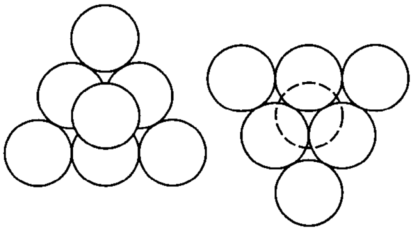
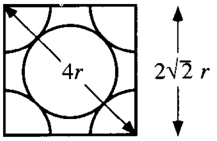
The PACKING DENSITIES for several packing types are summarized in the following table.

Packing	η (exact)	η (approx.)
square lattice (2-D)	$\frac{\pi}{4}$	0.7854
hexagonal lattice (2-D)	$\frac{\pi}{2\sqrt{3}}$	0.9069
cubic lattice	$\frac{\pi}{6}$	0.5236
hexagonal lattice	$\frac{\pi}{3\sqrt{3}}$	0.6046
face-centered cubic lattice	$\frac{\pi}{3\sqrt{2}}$	0.7405
random	—	0.6400



For cubic close packing, pack six SPHERES together in the shape of an EQUILATERAL TRIANGLE and place another SPHERE on top to create a TRIANGULAR PYRAMID. Now create another such grouping of seven SPHERES and place the two PYRAMIDS together facing in opposite directions. A CUBE emerges. Consider a face of the CUBE, illustrated below.



The "unit cell" cube contains eight 1/8-spheres (one at each VERTEX) and six HEMISPHERES. The total VOLUME of SPHERES in the unit cell is

$$\begin{aligned} V_{\text{spheres in unit cell}} &= (8\cdot\tfrac{1}{8} + 6\cdot\tfrac{1}{2})\frac{4\pi}{3}r^3 \\ &= 4\cdot\frac{4\pi}{3}r^3 = \tfrac{16}{3}\pi r^3. \end{aligned} \qquad (3)$$

The diagonal of the face is $4r$, so each side is $2\sqrt{2}\,r$. The VOLUME of the unit cell is therefore

$$V_{\text{unit cell}} = (2\sqrt{2}\,r)^3 = 16\sqrt{2}\,r^3. \qquad (4)$$

The PACKING DENSITY is therefore

$$\eta_{\text{CCP}} = \frac{\frac{16}{3}\pi r^2}{16\sqrt{2}r^3} = \frac{\pi}{3\sqrt{2}} \qquad (5)$$

(Conway and Sloane 1993, p. 2).

Hexagonal close packing must give the same values, since sliding one sheet of SPHERES cannot affect the volume they occupy. To verify this, construct a 3-D diagram containing a hexagonal unit cell with three layers. Both the top and the bottom contain six 1/6-SPHERES and one HEMISPHERE. The total number of spheres in these two rows is therefore

$$2(6\tfrac{1}{6} + 1\tfrac{1}{2}) = 3. \qquad (6)$$

The VOLUME of SPHERES in the middle row cannot be simply computed using geometry. However, symmetry requires that the piece of the SPHERE which is cut off is exactly balanced by an extra piece on the other side. There are therefore three SPHERES in the middle layer, for a total of six, and a total VOLUME

$$V_{\text{spheres in unit cell}} = 6\cdot\frac{4\pi}{3}r^3(3+3) = 8\pi r^3. \qquad (7)$$

The base of the HEXAGON is made up of 6 EQUILATERAL TRIANGLES with side lengths $2r$. The unit cell base AREA is therefore

$$A_{\text{unit cell}} = 6[\tfrac{1}{2}(2r)(\sqrt{3}\,r)] = 6\sqrt{3}\,r^2. \tag{8}$$

The height is the same as that of two TETRAHEDRA length $2r$ on a side, so

$$h_{\text{unit cell}} = 2\left(2r\sqrt{\frac{2}{3}}\right), \tag{9}$$

giving

$$\eta_{\text{HCP}} = \frac{8\pi r^3}{(6\sqrt{3}\,r^2)\left(4r\sqrt{\frac{2}{3}}\right)} = \frac{\pi}{3\sqrt{2}} \tag{10}$$

(Conway and Sloane 1993, pp. 7 and 9).

If we had actually wanted to compute the VOLUME of SPHERE inside and outside the HEXAGONAL PRISM, we could use the SPHERICAL CAP equation to obtain

$$\begin{aligned} V_{\subset} &= \tfrac{1}{3}\pi h^2(3r-h) = \frac{1}{3}\pi r^3 \frac{1}{3}\left(3 - \frac{1}{\sqrt{3}}\right) \\ &= \frac{1}{9}\pi r^3\left(3 - \frac{\sqrt{3}}{3}\right) = \tfrac{1}{27}\pi r^3(9-\sqrt{3}) \qquad (11) \\ V_{\supset} &= \pi r^3\left[\tfrac{4}{3} - \tfrac{1}{27}(9-\sqrt{3})\right] = \tfrac{1}{27}\pi r^3(36 - 9 + \sqrt{3}) \\ &= \tfrac{1}{27}\pi r^3(27+\sqrt{3}). \qquad (12) \end{aligned}$$

The rigid packing with *lowest* density known has $\eta \approx 0.0555$ (Gardner 1966). To be RIGID, each SPHERE must touch at least four others, and the four contact points cannot be in a single HEMISPHERE or all on one equator.

If spheres packed in a cubic lattice, face-centered cubic lattice, and hexagonal lattice are allowed to expand, they form cubes, hexagonal prisms, and rhombic dodecahedra. Compressing a random packing gives polyhedra with an average of 13.3 faces (Coxeter 1958, 1961).

For sphere packing inside a CUBE, see Goldberg (1971) and Schaer (1966).

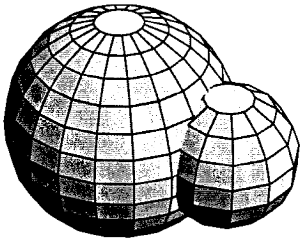
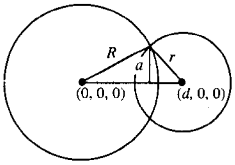
Sphere Point Picking

see FEJES TÓTH'S PROBLEM

Sphere-Sphere Intersection





Let two spheres of RADII R and r be located along the x-AXIS centered at $(0,0,0)$ and $(d,0,0)$, respectively. Not surprisingly, the analysis is very similar to the case of the CIRCLE-CIRCLE INTERSECTION. The equations of the two SPHERES are

$$x^2+y^2+z^2=R^2 \qquad (1)$$
$$(x-d)^2+y^2+z^2=r^2. \qquad (2)$$

Combining (1) and (2) gives

$$(x-d)^2+(R^2-x^2)=r^2. \qquad (3)$$

Multiplying through and rearranging give

$$x^2-2dx+d^2-x^2=r^2-R^2. \qquad (4)$$

Solving for x gives

$$x=\frac{d^2-r^2+R^2}{2d}. \qquad (5)$$

The intersection of the SPHERES is therefore a curve lying in a PLANE parallel to the yz-plane at a single x-coordinate. Plugging this back into (1) gives

$$\begin{aligned} y^2+z^2=R^2-x^2&=R^2-\left(\frac{d^2-r^2+R^2}{2d}\right)^2\\ &=\frac{4d^2R^2-(d^2-r^2+R^2)^2}{4d^2}, \qquad (6)\end{aligned}$$

which is a CIRCLE with RADIUS

$$\begin{aligned} a&=\frac{1}{2d}\sqrt{4d^2R^2-(d^2-r^2+R^2)^2}\\ &=\frac{1}{2d}[(-d+r-R)(-d-r+R)\\ &\quad\times[(-d+r+R)(d+r+R)]^{1/2}. \qquad (7)\end{aligned}$$

The VOLUME of the 3-D LENS common to the two spheres can be found by adding the two SPHERICAL CAPS. The distances from the SPHERES' centers to the bases of the caps are

$$d_1=x \qquad (8)$$
$$d_2=d-x, \qquad (9)$$

so the heights of the caps are

$$h_1=R-d_1=\frac{(r-R+d)(r+R-d)}{2d} \qquad (10)$$
$$h_2=r-d_2=\frac{(R-r+d)(R+r-d)}{2d}. \qquad (11)$$

The VOLUME of a SPHERICAL CAP of height h' for a SPHERE of RADIUS R' is

$$V(R',h')=\tfrac{1}{3}\pi h'^2(3R'-h'). \qquad (12)$$

Letting $R_1=R$ and $R_2=r$ and summing the two caps gives

$$\begin{aligned} V&=V(R_1,h_1)+V(R_2,h_2)\\ &=\frac{\pi(R+r-d)^2(d^2+2dr-3r^2+2dR+6rR-3R^2)}{12d}. \qquad (13)\end{aligned}$$

This expression gives $V=0$ for $d=r+R$ as it must. In the special case $r=R$, the VOLUME simplifies to

$$V=\tfrac{1}{12}\pi(4R+d)(2R-d)^2. \qquad (14)$$

see also APPLE, CIRCLE-CIRCLE INTERSECTION, DOUBLE BUBBLE, LENS, SPHERE

Sphere with Tunnel

Find the tunnel between two points A and B on a gravitating SPHERE which gives the shortest transit time under the force of gravity. Assume the SPHERE to be nonrotating, of RADIUS a, and with uniform density ρ. Then the standard form EULER-LAGRANGE DIFFERENTIAL EQUATION in polar coordinates is

$$r_{\phi\phi}(r^3-ra^2)+{r_\phi}^2(2a^2-r^2)+a^2r^2=0, \qquad (1)$$

along with the boundary conditions $r(\phi=0)=r_0$, $r_\phi(\phi=0)=0$, $r(\phi=\phi_A)=a$, and $r(\phi=\phi_B)=a$. Integrating once gives

$${r_\phi}^2=\frac{a^2r^2}{{r_0}^2}\frac{r^2-{r_0}^2}{a^2-r^2}. \qquad (2)$$

But this is the equation of a HYPOCYCLOID generated by a CIRCLE of RADIUS $\frac{1}{2}(a-r_0)$ rolling inside the CIRCLE of RADIUS a, so the tunnel is shaped like an arc of a HYPOCYCLOID. The transit time from point A to point B is

$$T=\pi\sqrt{\frac{a^2-{r_0}^2}{ag}}, \qquad (3)$$

where

$$g=\frac{GM}{a^2}=\tfrac{4}{3}\pi\rho Ga \qquad (4)$$

is the surface gravity with G the universal gravitational constant.

Spherical Bessel Differential Equation

Take the HELMHOLTZ DIFFERENTIAL EQUATION

$$\nabla^2F+k^2F=0 \qquad (1)$$

in SPHERICAL COORDINATES. This is just LAPLACE'S EQUATION in SPHERICAL COORDINATES with an additional term,

$$\begin{aligned}&\frac{d^2R}{dr^2}\Phi\Theta+\frac{2}{r}\frac{dR}{dr}+\frac{1}{r^2\sin^2\phi}\frac{d^2\Theta}{d\theta^2}\Phi R\\ &\quad+\frac{\cos\phi}{r^2\sin\phi}\frac{d\Phi}{d\phi}\Theta R+\frac{1}{r^2}\frac{d^2\Phi}{d\phi^2}+k^2R\Phi\Theta=0. \qquad (2)\end{aligned}$$

Multiply through by $r^2/R\Phi\Theta$,

$$\frac{r^2}{R}\frac{d^2R}{dr^2}+\frac{2r}{R}\frac{dR}{dr}+k^2r^2+\frac{1}{\Theta\sin^2\phi}\frac{d^2\Theta}{d\theta^2}+\frac{\cos\phi}{\Phi\sin\phi}\frac{d\Phi}{d\phi}+\frac{1}{\Phi}\frac{d^2\Phi}{d\phi^2}=0. \tag{3}$$

This equation is separable in R. Call the separation constant $n(n+1)$,

$$\frac{r^2}{R}\frac{d^2R}{dr^2}+\frac{2r}{R}\frac{dR}{dr}+k^2r^2=n(n+1). \tag{4}$$

Now multiply through by R,

$$r^2\frac{d^2R}{dr^2}+2r\frac{dR}{dr}+[k^2r^2-n(n+1)]R=0. \tag{5}$$

This is the SPHERICAL BESSEL DIFFERENTIAL EQUATION. It can be transformed by letting $x\equiv kr$, then

$$r\frac{dR(r)}{dr}=kr\frac{dR(r)}{k\,dr}=kr\frac{dR(r)}{d(kr)}=x\frac{dR(r)}{dx}. \tag{6}$$

Similarly,

$$r^2\frac{d^2R(r)}{dr^2}=x^2\frac{d^2R(r)}{dx^2}, \tag{7}$$

so the equation becomes

$$x^2\frac{d^2R}{dx^2}+2x\frac{dR}{dx}+[x^2-n(n+1)]R=0. \tag{8}$$

Now look for a solution of the form $R(r)=Z(x)x^{-1/2}$, denoting a derivative with respect to x by a prime,

$$R'=Z'x^{-1/2}-\tfrac{1}{2}Zx^{-3/2} \tag{9}$$

$$\begin{aligned}R''&=Z''x^{-1/2}-\tfrac{1}{2}Z'x^{-3/2}-\tfrac{1}{2}Z'x^{-3/2}\\&\quad-\tfrac{1}{2}(-\tfrac{3}{2})Zx^{-5/2}\\&=Z''x^{-1/2}-Z'x^{-3/2}+\tfrac{3}{4}Zx^{-5/2},\end{aligned} \tag{10}$$

so

$$\begin{aligned}&x^2(Z''x^{-1/2}-Z'x^{-3/2}+\tfrac{3}{4}Zx^{-5/2})\\&+2x(Z'x^{-1/2}-\tfrac{1}{2}Zx^{-3/2})+[x^2-n(n+1)]Zx^{-1/2}=0\end{aligned} \tag{11}$$

$$x^2(Z''-Z'x^{-1}+\tfrac{3}{4}Zx^{-2})+2x(Z'-\tfrac{1}{2}Zx^{-1})+[x^2-n(n+1)]Z=0 \tag{12}$$

$$x^2Z''+(-x+2x)Z'+[\tfrac{3}{4}-1+x^2-n(n+1)]Z=0 \tag{13}$$

$$\begin{aligned}&x^2Z''+xZ'+[x^2-(n^2+n+\tfrac{1}{4})]Z=0\\&x^2Z''+xZ'+[x^2-(n+\tfrac{1}{2})^2]Z=0.\end{aligned} \tag{14}$$

But the solutions to this equation are BESSEL FUNCTIONS of half integral order, so the normalized solutions to the original equation are

$$R(r)\equiv A\frac{J_{n+1/2}(kr)}{\sqrt{kr}}+B\frac{Y_{n+1/2}(kr)}{\sqrt{kr}} \tag{15}$$

which are known as SPHERICAL BESSEL FUNCTIONS. The two types of solutions are denoted $j_n(x)$ (SPHERICAL BESSEL FUNCTION OF THE FIRST KIND) or $n_n(x)$ (SPHERICAL BESSEL FUNCTION OF THE SECOND KIND), and the general solution is written

$$R(r)=A'j_n(kr)+B'n_n(kr), \tag{16}$$

where

$$j_n(z)\equiv\sqrt{\frac{\pi}{2}}\frac{J_{n+1/2}(z)}{\sqrt{z}} \tag{17}$$

$$n_n(z)\equiv\sqrt{\frac{\pi}{2}}\frac{Y_{n+1/2}(z)}{\sqrt{z}}. \tag{18}$$

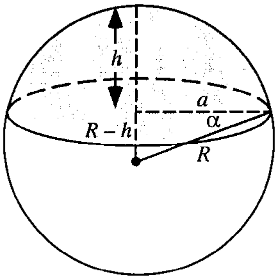
Spherical Bessel Function of the Third Kind

see SPHERICAL HANKEL FUNCTION OF THE FIRST KIND, SPHERICAL HANKEL FUNCTION OF THE SECOND KIND

Spherical Cap



A spherical cap is the region of a SPHERE which lies above (or below) a given PLANE. If the PLANE passes through the CENTER of the SPHERE, the cap is a HEMISPHERE. Let the SPHERE have RADIUS R, then the VOLUME of a spherical cap of height h and base RADIUS a is given by the equation of a SPHERICAL SEGMENT (which is a spherical cut by a second PLANE)

$$V_{\text{spherical segment}} = \tfrac{1}{6}\pi h(3a^2 + 3b^2 + h^2) \tag{1}$$

with $b = 0$, giving

$$V_{\text{cap}} = \tfrac{1}{6}\pi h(3a^2 + h^2). \tag{2}$$

Using the PYTHAGOREAN THEOREM gives

$$(R-h)^2 + a^2 = R^2, \tag{3}$$

which can be solved for a^2 as

$$a^2 = 2Rh - h^2, \tag{4}$$

and plugging this in gives the equivalent formula

$$V_{\text{cap}} = \tfrac{1}{3}\pi h^2(3R - h). \tag{5}$$

In terms of the so-called CONTACT ANGLE (the angle between the normal to the sphere at the bottom of the cap and the base plane)

$$R - h = R\sin\theta \tag{6}$$

$$\alpha \equiv \sin^{-1}\left(\frac{R-h}{R}\right), \tag{7}$$

so

$$V_{\text{cap}} = \tfrac{1}{3}\pi R^3(2 - 3\sin\alpha + \sin^3\alpha). \tag{8}$$

Consider a cylindrical box enclosing the cap so that the top of the box is tangent to the top of the SPHERE. Then the enclosing box has VOLUME

$$\begin{aligned} V_{\text{box}} = \pi a^2 h &= \pi(R\cos\alpha)[R(1-\sin\alpha)] \\ &= \pi R^3(1 - \sin\alpha - \sin^2\alpha + \sin^3\alpha), \end{aligned} \tag{9}$$

so the hollow volume between the cap and box is given by

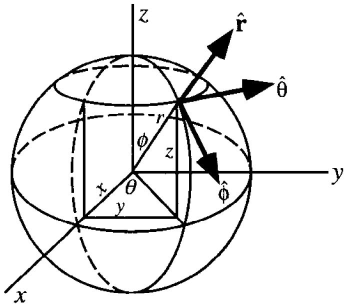
$$V_{\text{box}} - V_{\text{cap}} = \tfrac{1}{3}\pi R^3(1 - 3\sin^2\alpha + 2\sin^3\alpha). \tag{10}$$

If a second PLANE cuts the cap, the resulting SPHERICAL FRUSTUM is called a SPHERICAL SEGMENT. The SURFACE AREA of the spherical cap is given by the same equation as for a general ZONE:

$$S_{\text{cap}} = 2\pi Rh. \tag{11}$$

see also CONTACT ANGLE, DOME, FRUSTUM, HEMISPHERE, SOLID OF REVOLUTION, SPHERE, SPHERICAL SEGMENT, TORISPHERICAL DOME, ZONE

Spherical Coordinates



A system of CURVILINEAR COORDINATES which is natural for describing positions on a SPHERE or SPHEROID. Define θ to be the azimuthal ANGLE in the xy-PLANE from the x-AXIS with $0 \leq \theta < 2\pi$ (denoted λ when referred to as the LONGITUDE), ϕ to be the polar ANGLE from the z-AXIS with $0 \leq \phi \leq \pi$ (COLATITUDE, equal to $\phi = 90° - \delta$ where δ is the LATITUDE), and r to be distance (RADIUS) from a point to the ORIGIN.

Unfortunately, the convention in which the symbols θ and ϕ are reversed is frequently used, especially in physics, leading to unnecessary confusion. The symbol ρ is sometimes also used in place of r. Arfken (1985) uses (r, ϕ, θ), whereas Beyer (1987) uses (ρ, θ, ϕ). Be very careful when consulting the literature.

In this work, the symbols for the azimuthal, polar, and radial coordinates are taken as θ, ϕ, and r, respectively. Note that this definition provides a logical extension of the usual POLAR COORDINATES notation, with θ remaining the ANGLE in the xy-PLANE and ϕ becoming the ANGLE out of the PLANE.

$$r = \sqrt{x^2 + y^2 + z^2} \tag{1}$$

$$\theta = \tan^{-1}\left(\frac{y}{x}\right) \tag{2}$$

$$\phi = \sin^{-1}\left(\frac{\sqrt{x^2+y^2}}{r}\right) = \cos^{-1}\left(\frac{z}{r}\right), \tag{3}$$

where $r \in [0, \infty)$, $\theta \in [0, 2\pi)$, and $\phi \in [0, \pi]$. In terms of CARTESIAN COORDINATES,

$$x = r\cos\theta\sin\phi \tag{4}$$

$$y = r\sin\theta\sin\phi \tag{5}$$

$$z = r\cos\phi. \tag{6}$$

The SCALE FACTORS are

$$h_r = 1 \tag{7}$$

$$h_\theta = r\sin\phi \tag{8}$$

$$h_\phi = r, \tag{9}$$

so the METRIC COEFFICIENTS are

$$g_{rr} = 1 \qquad (10)$$

$$g_{\theta\theta} = r^2 \sin^2 \phi \qquad (11)$$

$$g_{\phi\phi} = r^2. \qquad (12)$$

The LINE ELEMENT is

$$d\mathbf{s} = dr\,\hat{\mathbf{r}} + r\,d\phi\,\hat{\boldsymbol{\phi}} + r\sin\phi\,d\theta\,\hat{\boldsymbol{\theta}}, \qquad (13)$$

the AREA element

$$d\mathbf{a} = r^2 \sin\phi\,d\theta\,d\phi\,\hat{\mathbf{r}}, \qquad (14)$$

and the VOLUME ELEMENT

$$dV = r^2 \sin\phi\,d\theta\,d\phi\,dr. \qquad (15)$$

The JACOBIAN is

$$\left|\frac{\partial(x,y,z)}{\partial(r,\theta,\phi)}\right| = r^2|\sin\phi|. \qquad (16)$$

The POSITION VECTOR is

$$\mathbf{r} \equiv \begin{bmatrix} r\cos\theta\sin\phi \\ r\sin\theta\sin\phi \\ r\cos\phi \end{bmatrix}, \qquad (17)$$

so the UNIT VECTORS are

$$\hat{\mathbf{r}} \equiv \frac{\frac{d\mathbf{r}}{dr}}{\left|\frac{d\mathbf{r}}{dr}\right|} = \begin{bmatrix} \cos\theta\sin\phi \\ \sin\theta\sin\phi \\ \cos\phi \end{bmatrix} \qquad (18)$$

$$\hat{\boldsymbol{\theta}} \equiv \frac{\frac{d\mathbf{r}}{d\theta}}{\left|\frac{d\mathbf{r}}{d\theta}\right|} = \begin{bmatrix} -\sin\theta \\ \cos\theta \\ 0 \end{bmatrix} \qquad (19)$$

$$\hat{\boldsymbol{\phi}} \equiv \frac{\frac{d\mathbf{r}}{d\phi}}{\left|\frac{d\mathbf{r}}{d\phi}\right|} = \begin{bmatrix} \cos\theta\cos\phi \\ \sin\theta\cos\phi \\ -\sin\phi \end{bmatrix}. \qquad (20)$$

Derivatives of the UNIT VECTORS are

$$\frac{\partial\hat{\mathbf{r}}}{\partial r} = \mathbf{0} \qquad (21)$$

$$\frac{\partial\hat{\boldsymbol{\theta}}}{\partial r} = \mathbf{0} \qquad (22)$$

$$\frac{\partial\hat{\boldsymbol{\phi}}}{\partial r} = \mathbf{0} \qquad (23)$$

$$\frac{\partial\hat{\mathbf{r}}}{\partial\theta} = \begin{bmatrix} -\sin\theta\sin\phi \\ \cos\theta\sin\phi \\ 0 \end{bmatrix} = \sin\phi\,\hat{\boldsymbol{\theta}} \qquad (24)$$

$$\frac{\partial\hat{\boldsymbol{\theta}}}{\partial\theta} = \begin{bmatrix} -\cos\theta \\ -\sin\theta \\ 0 \end{bmatrix} = -\cos\phi\,\hat{\boldsymbol{\phi}} - \sin\phi\,\hat{\mathbf{r}} \qquad (25)$$

$$\frac{\partial\hat{\boldsymbol{\phi}}}{\partial\theta} = \begin{bmatrix} -\sin\theta\cos\phi \\ \cos\theta\cos\phi \\ 0 \end{bmatrix} = \cos\phi\,\hat{\boldsymbol{\theta}} \qquad (26)$$

$$\frac{\partial\hat{\mathbf{r}}}{\partial\phi} = \begin{bmatrix} \cos\theta \\ \sin\theta\cos\phi \\ -\sin\phi \end{bmatrix} = \hat{\boldsymbol{\phi}} \qquad (27)$$

$$\frac{\partial\hat{\boldsymbol{\theta}}}{\partial\phi} = \mathbf{0} \qquad (28)$$

$$\frac{\partial\hat{\boldsymbol{\phi}}}{\partial\phi} = \begin{bmatrix} -\cos\theta\sin\phi \\ -\sin\theta\sin\phi \\ -\cos\phi \end{bmatrix} = -\hat{\mathbf{r}}. \qquad (29)$$

The GRADIENT is

$$\nabla = \hat{\mathbf{r}}\frac{\partial}{\partial r} + \frac{1}{r}\hat{\boldsymbol{\phi}}\frac{\partial}{\partial\phi} + \frac{1}{r\sin\phi}\hat{\boldsymbol{\theta}}\frac{\partial}{\partial\theta}, \qquad (30)$$

so

$$\nabla_r\hat{\mathbf{r}} = \mathbf{0} \qquad (31)$$

$$\nabla_r\hat{\boldsymbol{\theta}} = \mathbf{0} \qquad (32)$$

$$\nabla_r\hat{\boldsymbol{\phi}} = \hat{\mathbf{0}} \qquad (33)$$

$$\nabla_\theta\hat{\mathbf{r}} = \frac{\sin\phi\,\hat{\boldsymbol{\theta}}}{r\sin\phi} = \frac{1}{r}\hat{\boldsymbol{\theta}} \qquad (34)$$

$$\nabla_\theta\hat{\boldsymbol{\theta}} = -\frac{\cos\phi\,\hat{\boldsymbol{\phi}} + \sin\phi\,\hat{\mathbf{r}}}{r\sin\phi} = -\frac{\cot\phi}{r}\hat{\boldsymbol{\phi}} - \frac{1}{r}\hat{\mathbf{r}} \qquad (35)$$

$$\nabla_\theta\hat{\boldsymbol{\phi}} = \frac{\cos\phi\,\hat{\boldsymbol{\phi}}}{r\sin\phi} = \frac{1}{r}\cot\phi\,\hat{\boldsymbol{\theta}}. \qquad (36)$$

Now, since the CONNECTION COEFFICIENTS are given by $\Gamma^i_{jk} = \hat{\mathbf{x}}_i \cdot (\nabla_k \hat{\mathbf{x}}_j)$,

$$\Gamma^\theta = \begin{bmatrix} 0 & \frac{1}{r} & 0 \\ 0 & 0 & 0 \\ 0 & \frac{\cot\phi}{r} & 0 \end{bmatrix} \qquad (37)$$

$$\Gamma^\phi = \begin{bmatrix} 0 & 0 & \frac{1}{r} \\ 0 & -\frac{\cot\phi}{r} & 0 \\ 0 & 0 & 0 \end{bmatrix} \qquad (38)$$

$$\Gamma^r = \begin{bmatrix} 0 & 0 & 0 \\ 0 & -\frac{1}{r} & 0 \\ 0 & 0 & -\frac{1}{r} \end{bmatrix}. \qquad (39)$$

The DIVERGENCE is

$$\begin{aligned}
\nabla \cdot \mathbf{F} &= A^k{}_{,k} + \Gamma^k_{jk}A^j \\
&= [A^r{}_{,r} + (\Gamma^r_{rr}A^r + \Gamma^r_{\theta r}A^\theta + \Gamma^r_{\phi r}A^\phi] \\
&\quad + [A^\theta{}_{,\theta} + (\Gamma^\theta_{r\theta}A^r + \Gamma^\theta_{\theta\theta}A^\theta + \Gamma^\theta_{\phi\theta}A^\phi)] \\
&\quad + [A^\phi{}_{,\phi} + (\Gamma^\phi_{r\phi}A^r + \Gamma^\phi_{\theta\phi}A^\theta + \Gamma^\phi_{\phi\phi}A^\phi)] \\
&= \frac{1}{g_r}\frac{\partial A^r}{\partial r} + \frac{1}{g_\theta}\frac{\partial A^\theta}{\partial\theta} + \frac{1}{g_\phi}\frac{\partial A^\phi}{\partial\phi} + (0+0+0) \\
&\quad + \left(\frac{1}{r}A^r + 0 + \frac{\cot\phi}{r}A^\phi\right) + \left(\frac{1}{r}A^r + 0 + 0\right) \\
&= \frac{\partial}{\partial r}A^r + \frac{2}{r}A^r + \frac{1}{r\sin\phi}\frac{\partial}{\partial\theta}A^\theta + \frac{1}{r}\frac{\partial}{\partial\phi}A^\phi + \frac{\cot\phi}{r}A^\phi,
\end{aligned} \qquad (40)$$

or, in VECTOR notation,

$$\begin{aligned}
\nabla \cdot \mathbf{F} &= \left(\frac{2}{r} + \frac{\partial}{\partial r}\right)F_r + \left(\frac{1}{r}\frac{\partial}{\partial\phi} + \frac{\cot\phi}{r}\right)F_\phi + \frac{1}{\sin\phi}\frac{\partial F_\theta}{\partial\theta} \\
&= \frac{1}{r^2}\frac{\partial}{\partial r}(r^2F_r) + \frac{1}{r\sin\phi}\frac{\partial}{\partial\phi}(\sin\phi F_\phi) + \frac{1}{r\sin\phi}\frac{\partial F_\theta}{\partial\theta}.
\end{aligned} \qquad (41)$$

The COVARIANT DERIVATIVES are given by

$$A_{j;k} = \frac{1}{g_{kk}}\frac{\partial A_j}{\partial x_k} - \Gamma^i_{jk}A_i, \qquad (42)$$

so

$$\begin{aligned}
A_{r;r} &= \frac{\partial A_r}{\partial r} - \Gamma^i_{rr} A_i = \frac{\partial A_r}{\partial r} && (43)\\
A_{r;\theta} &= \frac{1}{r\sin\phi}\frac{\partial A_r}{\partial\theta} - \Gamma^i_{r\theta} = \frac{1}{r\sin\phi}\frac{\partial A_r}{\partial\theta} - \Gamma_{r\theta}A_\theta\\
&= \frac{1}{r\sin\phi}\frac{\partial A_r}{\partial\phi} - \frac{A_\theta}{r} && (44)\\
A_{r;\phi} &= \frac{1}{r}\frac{\partial A_r}{\partial\phi} - \Gamma^i_{r\phi}A_i = \frac{1}{r}\frac{\partial A_r}{\partial\phi} - \Gamma^\phi_{r\phi}A_\phi\\
&= \frac{1}{r}\left(\frac{\partial A_r}{\partial\phi} - A_\phi\right) && (45)\\
A_{\theta;r} &= \frac{\partial A_\theta}{\partial r} - \Gamma^i_{\theta r}A_i = \frac{\partial A_\theta}{\partial r} && (46)\\
A_{\theta;\theta} &= \frac{1}{r\sin\phi}\frac{\partial A_\phi}{\partial\theta} - \Gamma^i_{\theta\theta}A_i\\
&= \frac{1}{r\sin\phi}\partial A_\theta \partial\theta - \Gamma^\phi_{\theta\theta}A_\phi - \Gamma^r_{\theta\theta}A_r\\
&= \frac{1}{r\sin\phi}\frac{\partial A_\theta}{\partial\theta} + \frac{\cot\phi}{r}A_\phi + \frac{A_r}{r} && (47)\\
A_{\theta;\phi} &= \frac{1}{r}\frac{\partial A_\theta}{\partial r} - \Gamma^i_{\phi r}A_i\frac{\partial A_\theta}{\partial\phi} && (48)\\
A_{\phi;r} &= \frac{\partial A_\phi}{\partial r} - \Gamma^i_{\phi r}A_i = \frac{\partial A_\phi}{r} && (49)\\
A_{\phi;\theta} &= \frac{1}{r\sin\phi}\frac{\partial A_\phi}{\partial\theta} - \Gamma^i_{\phi\theta}A_i = \frac{1}{r\sin\phi}\frac{\partial A_\phi}{\partial\theta} - \Gamma^\theta_{\phi\theta}\\
&= \frac{1}{r\sin\phi}\frac{\partial A_\phi}{\partial\theta} - \frac{\cot\phi}{r}A_\theta && (50)\\
A_{\phi;\phi} &= \frac{1}{r}\frac{\partial A_\phi}{\partial\phi} - \Gamma^i_{\phi\phi}A_i = \frac{1}{r}\frac{\partial A_\phi}{\partial\phi} - \Gamma^r_{\phi\phi}A_r\\
&= \frac{1}{r}\frac{\partial A_\phi}{\partial\phi} + \frac{A_r}{r}. && (51)
\end{aligned}$$

The Commutation Coefficients are given by

$$c^\mu_{\alpha\beta}\vec{e}_\mu = [\vec{e}_\alpha, \vec{e}_\beta] = \nabla_\alpha\vec{e}_\beta - \nabla_\beta\vec{e}_\alpha \qquad (52)$$

$$[\hat{\mathbf{r}}, \hat{\mathbf{r}}] = [\hat{\boldsymbol{\theta}}, \hat{\boldsymbol{\theta}}] = [\hat{\boldsymbol{\phi}}, \hat{\boldsymbol{\phi}}] = \mathbf{0}, \qquad (53)$$

so $c^\alpha_{rr} = c^\alpha_{\theta\theta} = c^\alpha_{\phi\phi} = 0$, where $\alpha = r, \theta, \phi$.

$$[\hat{\mathbf{r}}, \hat{\boldsymbol{\theta}}] = -[\hat{\boldsymbol{\theta}}, \hat{\mathbf{r}}] = \nabla_r\hat{\boldsymbol{\theta}} - \nabla_\theta\hat{\mathbf{r}} = \mathbf{0} - \frac{1}{r}\hat{\boldsymbol{\theta}} = -\frac{1}{r}\hat{\boldsymbol{\theta}}, \qquad (54)$$

so $c^\theta_{r\theta} = -c^\theta_{\theta r} = -\frac{1}{r}$, $c^r_{r\theta} = c^\phi_{r\theta} = 0$.

$$[\hat{\mathbf{r}}, \hat{\boldsymbol{\phi}}] = -[\hat{\boldsymbol{\phi}}, \hat{\mathbf{r}}] = \mathbf{0} - \frac{1}{r}\hat{\boldsymbol{\phi}} = -\frac{1}{r}\hat{\boldsymbol{\phi}}, \qquad (55)$$

so $c^\phi_{r\phi} = -c^\phi_{\phi r} = \frac{1}{r}$.

$$[\hat{\boldsymbol{\theta}}, \hat{\boldsymbol{\phi}}] = -[\hat{\boldsymbol{\phi}}, \hat{\boldsymbol{\theta}}] = \frac{1}{r}\cot\phi\hat{\boldsymbol{\theta}} - \mathbf{0} = \frac{1}{r}\cot\phi\hat{\boldsymbol{\theta}}, \qquad (56)$$

so

$$c^\theta_{\theta\phi} = -c^\theta_{\phi\theta} = \frac{1}{r}\cot\phi. \qquad (57)$$

Summarizing,

$$c^r = \begin{bmatrix} 0 & 0 & 0\\ 0 & 0 & 0\\ 0 & 0 & 0 \end{bmatrix} \qquad (58)$$

$$c^\theta = \begin{bmatrix} 0 & -\frac{1}{r} & 0\\ \frac{1}{r} & 0 & \frac{1}{r}\cot\phi\\ 0 & -\frac{1}{r}\cot\phi & 0 \end{bmatrix} \qquad (59)$$

$$c^\phi = \begin{bmatrix} 0 & 0 & -\frac{1}{r}\\ 0 & 0 & 0\\ \frac{1}{r} & 0 & 0 \end{bmatrix}. \qquad (60)$$

Time derivatives of the Position Vector are

$$\begin{aligned}
\dot{\mathbf{r}} &= \begin{bmatrix} \cos\theta\sin\phi\,\dot{r} - r\sin\theta\sin\phi\,\dot{\theta} + r\cos\theta\cos\phi\,\dot{\phi}\\ \sin\theta\sin\phi\,\dot{r} + r\cos\theta\sin\phi\,\dot{\theta} + r\sin\theta\cos\phi\,\dot{\phi}\\ \cos\phi\,\dot{r} - r\sin\phi\,\dot{\phi} \end{bmatrix}\\
&= \begin{bmatrix} \cos\theta\sin\phi\\ \sin\theta\sin\phi\\ \cos\phi \end{bmatrix}\dot{r} + r\sin\phi\begin{bmatrix} -\sin\theta\\ \cos\theta\\ 0 \end{bmatrix}\dot{\theta}\\
&\quad + r\begin{bmatrix} \cos\theta\cos\phi\\ \sin\theta\cos\phi\\ -\sin\phi \end{bmatrix}\dot{\phi}\\
&= \dot{r}\,\hat{\mathbf{r}} + r\sin\phi\,\dot{\theta}\,\hat{\boldsymbol{\theta}} + r\,\dot{\phi}\,\hat{\boldsymbol{\phi}}. && (61)
\end{aligned}$$

The Speed is therefore given by

$$v \equiv |\dot{\mathbf{r}}| = \sqrt{\dot{r}^2 + r^2\sin^2\phi\dot{\theta}^2 + r^2\dot{\phi}^2}. \qquad (62)$$

The Acceleration is

$$\begin{aligned}
\ddot{x} &= (-\sin\theta\sin\phi\dot{\theta}\dot{r} + \cos\theta\cos\phi\dot{r}\dot{\phi} + \cos\theta\sin\phi\ddot{r})\\
&\quad - (\sin\theta\sin\phi\dot{r}\dot{\theta} + r\cos\theta\sin\phi\dot{\theta}^2 + r\sin\theta\cos\phi\dot{\theta}\dot{\phi}\\
&\quad + r\sin\theta\sin\phi\ddot{\theta}) + (\cos\theta\cos\phi\dot{r}\dot{\phi} - r\sin\theta\cos\dot{\theta}\dot{\phi}\\
&\quad - r\cos\theta\sin\phi\dot{\phi}^2 + r\cos\theta\cos\phi\ddot{\phi})\\
&= -2\sin\theta\sin\phi\dot{\theta}\dot{r} + 2\cos\theta\cos\phi\dot{r}\dot{\phi} - 2r\sin\theta\cos\phi\dot{\theta}\dot{\phi}\\
&\quad + \cos\theta\sin\phi\ddot{r} - r\sin\theta\sin\phi\ddot{\theta} + r\cos\theta\cos\phi\ddot{\phi}\\
&\quad - r\cos\theta\sin\phi(\dot{\theta}^2 + \dot{\phi}^2) && (63)\\
\ddot{y} &= (\sin\theta\sin\phi\ddot{r} + r\cos\theta\sin\phi\dot{\theta} + r\cos\phi\sin\theta\dot{\phi})\\
&\quad + (\cos\theta\sin\phi\dot{r}\dot{\theta} - r\sin\theta\sin\phi\dot{\theta}^2 + r\cos\theta\cos\phi\dot{\theta}\dot{\phi}\\
&\quad + r\cos\theta\sin\phi\ddot{\theta}) + (\sin\theta\cos\phi\dot{r}\dot{\phi} + r\cos\theta\cos\phi\dot{\theta}\dot{\phi}\\
&\quad - r\sin\theta\sin\phi\dot{\phi}^2 + r\sin\theta\cos\phi\ddot{\phi})\\
&= 2\cos\theta\sin\phi\dot{\theta}\dot{r} + 2\sin\theta\cos\phi\dot{r}\dot{\phi} + 2r\cos\theta\cos\phi\dot{\theta}\dot{\phi}\\
&\quad + \sin\theta\sin\phi\ddot{r} + r\cos\theta\sin\phi\ddot{\theta} + r\sin\theta\cos\phi\ddot{\phi}\\
&\quad - r\sin\theta\sin\phi(\dot{\theta}^2 + \dot{\phi}^2) && (64)\\
\ddot{z} &= (\cos\phi\ddot{r} - \sin\phi\dot{r}\dot{\phi}) - (\dot{r}\sin\phi\dot{\phi} + r\cos\phi\dot{\phi}^2 + r\sin\phi\ddot{\phi})\\
&= -r\cos\phi\dot{\phi}^2 + \cos\phi\ddot{r} - 2\sin\phi\dot{\phi}\dot{r} - r\sin\phi\ddot{\phi}. && (65)
\end{aligned}$$

Plugging these in gives

$$\ddot{\mathbf{r}} = (\ddot{r} - r\dot{\phi}^2)\begin{bmatrix}\cos\theta\sin\phi\\ \sin\theta\sin\phi\\ \cos\phi\end{bmatrix} + (2r\cos\phi\dot{\theta}\dot{\phi} + r\sin\phi\ddot{\theta})\begin{bmatrix}-\sin\theta\\ \cos\theta\\ 0\end{bmatrix} + (2\dot{r}\dot{\phi} + r\ddot{\phi})\begin{bmatrix}\cos\theta\cos\phi\\ \sin\theta\cos\phi\\ -\sin\phi\end{bmatrix} - r\sin\phi\dot{\theta}^2\begin{bmatrix}\cos\theta\\ \sin\theta\\ 0\end{bmatrix}, \tag{66}$$

but

$$\sin\phi\hat{\mathbf{r}} + \cos\phi\hat{\boldsymbol{\phi}} = \begin{bmatrix}\cos\theta\sin^2\phi + \cos\theta\cos^2\phi\\ \sin\theta\sin^2\phi + \sin\theta\cos^2\phi\\ 0\end{bmatrix} = \begin{bmatrix}\cos\theta\\ \sin\theta\\ 0\end{bmatrix}, \tag{67}$$

so

$$\begin{aligned}\ddot{\mathbf{r}} &= (\ddot{r} - r\dot{\phi}^2)\hat{\mathbf{r}} + (2r\cos\phi\dot{\theta}\dot{\phi} + 2\sin\phi\dot{\theta}\dot{r} + r\sin\phi\ddot{\theta})\hat{\boldsymbol{\theta}}\\ &\quad + (2\dot{r}\dot{\phi} + r\ddot{\phi})\hat{\boldsymbol{\phi}} - r\sin\phi\dot{\theta}^2(\sin\phi\hat{\mathbf{r}} + \cos\phi\hat{\boldsymbol{\phi}})\\ &= (\ddot{r} - r\dot{\phi}^2 - r\sin^2\phi\dot{\theta}^2)\hat{\mathbf{r}}\\ &\quad + (2\sin\phi\dot{\theta}\dot{r} + 2r\cos\phi\dot{\theta}\dot{\phi} + r\sin\phi\ddot{\theta})\hat{\boldsymbol{\theta}}\\ &\quad + (2\dot{r}\dot{\phi} + r\ddot{\phi} - r\sin\phi\cos\phi\dot{\theta}^2)\hat{\boldsymbol{\phi}}.\end{aligned} \tag{68}$$

Time DERIVATIVES of the UNIT VECTORS are

$$\dot{\hat{\mathbf{r}}} = \begin{bmatrix}-\sin\theta\sin\phi\,\dot{\theta} + \cos\theta\cos\phi\,\dot{\phi}\\ \cos\theta\sin\phi\,\dot{\theta} + \sin\theta\cos\phi\,\dot{\phi}\\ -\sin\phi\,\dot{\phi}\end{bmatrix} = \sin\phi\,\dot{\theta}\hat{\boldsymbol{\theta}} + \dot{\phi}\hat{\boldsymbol{\phi}} \tag{69}$$

$$\dot{\hat{\boldsymbol{\theta}}} = \begin{bmatrix}-\cos\theta\dot{\theta}\\ -\sin\theta\dot{\theta}\\ 0\end{bmatrix} = -\dot{\theta}\begin{bmatrix}\cos\theta\\ \sin\theta\\ 0\end{bmatrix} = -\dot{\theta}(\sin\phi\hat{\mathbf{r}} + \cos\phi\hat{\boldsymbol{\phi}}) \tag{70}$$

$$\dot{\hat{\boldsymbol{\phi}}} = \begin{bmatrix}-\sin\theta\cos\phi\,\dot{\theta} - \cos\theta\sin\phi\,\dot{\phi}\\ \cos\theta\cos\phi\,\dot{\theta} - \sin\theta\sin\phi\,\dot{\phi}\\ -\cos\phi\,\dot{\phi}\end{bmatrix} = -\dot{\phi}\hat{\mathbf{r}} + \cos\phi\dot{\theta}\hat{\boldsymbol{\theta}}. \tag{71}$$

The CURL is

$$\nabla\times\mathbf{F} = \frac{1}{r\sin\phi}\left[\frac{\partial}{\partial\phi}(\sin\phi F_\theta) - \frac{\partial F_\phi}{\partial\theta}\right]\hat{\mathbf{r}} + \frac{1}{r}\left[\frac{1}{\sin\phi}\frac{\partial F_r}{\partial\theta} - \frac{\partial}{\partial r}(rF_\theta)\right]\hat{\boldsymbol{\phi}} + \frac{1}{r}\left[\frac{\partial}{\partial r}(rF_\phi) - \frac{\partial F_r}{\partial\phi}\right]\hat{\boldsymbol{\theta}}. \tag{72}$$

The LAPLACIAN is

$$\begin{aligned}\nabla^2 &\equiv \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) + \frac{1}{r^2\sin^2\phi}\frac{\partial^2}{\partial\theta^2}\\ &\quad + \frac{1}{r^2\sin\phi}\frac{\partial}{\partial\phi}\left(\sin\phi\frac{\partial}{\partial\phi}\right)\\ &= \frac{1}{r^2}\left(r^2\frac{\partial^2}{\partial r^2} + 2r\frac{\partial}{\partial r}\right) + \frac{1}{r^2\sin^2\phi}\frac{\partial^2}{\partial\theta^2}\\ &\quad + \frac{1}{r^2\sin\phi}\left(\cos\phi\frac{\partial}{\partial\phi} + \sin\phi\frac{\partial^2}{\partial\phi^2}\right)\\ &= \frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r} + \frac{1}{r^2\sin^2\phi}\frac{\partial^2}{\partial\theta^2}\\ &\quad + \frac{\cos\phi}{r^2\sin\phi}\frac{\partial}{\partial\phi} + \frac{1}{r^2}\frac{\partial^2}{\partial\phi^2}.\end{aligned} \tag{73}$$

The vector LAPLACIAN is

$$\nabla^2\mathbf{v} = \begin{bmatrix}\frac{1}{r}\frac{\partial^2(rv_r)}{\partial r^2} + \frac{1}{r^2}\frac{\partial^2 v_r}{\partial\theta^2} + \frac{1}{r^2\sin^2\theta}\frac{\partial^2 v_r}{\partial\phi^2} + \frac{\cot\theta}{r^2}\frac{\partial v_r}{\theta}\\ \quad - \frac{2}{r^2}\frac{\partial v_\theta}{\partial\theta} - \frac{2}{r^2\sin\theta}\frac{\partial v_\phi}{\partial\phi} - \frac{2v_r}{r^2} - \frac{2\cot\theta}{r^2}v_\theta\\ \frac{1}{r}\frac{\partial^2(rv_\theta)}{\partial r^2} + \frac{1}{r^2}\frac{\partial^2 v_\theta}{\partial\theta^2} + \frac{1}{r^2\sin^2\theta}\frac{\partial^2 v_\theta}{\partial\phi^2} + \frac{\cot\theta}{r^2}\frac{\partial v_\theta}{\partial\theta}\\ \quad - \frac{2}{r^2}\frac{2\cot\theta}{r^2\sin\theta}\frac{\partial v_\phi}{\partial\phi} + \frac{2}{r^2}\frac{\partial v_r}{\partial\theta} - \frac{v_\theta}{r^2\sin^2\theta}\\ \frac{1}{r}\frac{\partial^2(rv_\phi)}{\partial r^2} + \frac{1}{r^2}\frac{\partial^2 v_\phi a}{\partial\theta^2} + \frac{1}{r^2\sin^2\theta}\frac{\partial^2 v_\phi}{\partial\phi^2} + \frac{\cot\theta}{r^2}\frac{\partial v_\phi}{\partial\theta}\\ \quad + \frac{2}{r^2}\frac{\partial v_r}{\partial\phi} + \frac{2\cot\theta}{r^2\sin\theta}\frac{\partial v_\theta}{\partial\phi} - \frac{v_\phi}{r^2\sin^2\theta}\end{bmatrix}. \tag{74}$$

To express PARTIAL DERIVATIVES with respect to Cartesian axes in terms of PARTIAL DERIVATIVES of the spherical coordinates,

$$\begin{bmatrix}x\\ y\\ z\end{bmatrix} = \begin{bmatrix}r\cos\theta\sin\phi\\ r\sin\theta\sin\phi\\ r\cos\phi\end{bmatrix} \tag{75}$$

$$\begin{bmatrix}dx\\ dy\\ dz\end{bmatrix} = \begin{bmatrix}\cos\theta\sin\phi\,dr - r\sin\theta\sin\phi\,d\theta + r\cos\theta\cos\phi\,d\phi\\ \sin\theta\sin\phi\,dr + r\sin\phi\cos\theta\,d\theta + r\sin\theta\cos\phi\,d\phi\\ \cos\phi\,dr - r\sin\phi\,d\phi\end{bmatrix} = \begin{bmatrix}\cos\theta\sin\phi & -r\sin\theta\sin\phi & r\cos\theta\cos\phi\\ \sin\theta\sin\phi & r\sin\phi\cos\theta & r\sin\theta\cos\phi\\ \cos\phi & 0 & -r\sin\phi\end{bmatrix}\begin{bmatrix}dr\\ d\theta\\ d\phi\end{bmatrix}. \tag{76}$$

Upon inversion, the result is

$$\begin{bmatrix}dr\\ d\theta\\ d\phi\end{bmatrix} = \begin{bmatrix}\cos\theta\sin\phi & \sin\theta\sin\phi & \cos\phi\\ -\frac{\sin\theta}{r\sin\phi} & \frac{\cos\theta}{r\sin\phi} & 0\\ \frac{\cos\theta\cos\phi}{r} & \frac{\sin\theta\cos\phi}{r} & -\frac{\sin\phi}{r}\end{bmatrix}\begin{bmatrix}dx\\ dy\\ dz\end{bmatrix}. \tag{77}$$

The Cartesian PARTIAL DERIVATIVES in spherical coordinates are therefore

$$\begin{aligned}\frac{\partial}{\partial x} &= \frac{\partial r}{\partial x}\frac{\partial}{\partial r} + \frac{\partial \theta}{\partial x}\frac{\partial}{\partial \theta} + \frac{\partial \phi}{\partial x}\frac{\partial}{\partial \phi} \\ &= \cos\theta\sin\phi\frac{\partial}{\partial r} - \frac{\sin\theta}{r\sin\phi}\frac{\partial}{\partial\theta} + \frac{\cos\theta\cos\phi}{r}\frac{\partial}{\partial\phi}\end{aligned} \tag{78}$$

$$\begin{aligned}\frac{\partial}{\partial y} &= \frac{\partial r}{\partial y}\frac{\partial}{\partial r} + \frac{\partial \theta}{\partial y}\frac{\partial}{\partial \theta} + \frac{\partial \phi}{\partial y}\frac{\partial}{\partial \phi} \\ &= \sin\theta\sin\phi\frac{\partial}{\partial r} + \frac{\cos\theta}{r\sin\phi}\frac{\partial}{\partial\theta} + \frac{\sin\theta\cos\phi}{r}\frac{\partial}{\partial\phi}\end{aligned} \tag{79}$$

$$\begin{aligned}\frac{\partial}{\partial z} &= \frac{\partial r}{\partial z}\frac{\partial}{\partial r} + \frac{\partial \theta}{\partial z}\frac{\partial}{\partial \theta} + \frac{\partial \phi}{\partial z}\frac{\partial}{\partial \phi} \\ &= \cos\phi\frac{\partial}{\partial r} - \frac{\sin\phi}{r}\frac{\partial}{\partial\phi}\end{aligned} \tag{80}$$

(Gasiorowicz 1974, pp. 167–168).

The HELMHOLTZ DIFFERENTIAL EQUATION is separable in spherical coordinates.

Spherical Design

X is a spherical t-design in E IFF it is possible to exactly determine the average value on E of any POLYNOMIAL f of degree at most t by sampling f at the points of X. In other words,

$$\frac{1}{\text{volume } E}\int_E f(\xi)\,d\xi = \frac{1}{|X|}\sum_{x\in X} f(x).$$

Spherical Frustum

see SPHERICAL SEGMENT

Spherical Geometry

The study of figures on the surface of a SPHERE (such as the SPHERICAL TRIANGLE and SPHERICAL POLYGON), as opposed to the type of geometry studied in PLANE GEOMETRY or SOLID GEOMETRY.

see also PLANE GEOMETRY, SOLID GEOMETRY, SPHERICAL TRIGONOMETRY, THURSTON'S GEOMETRIZATION CONJECTURE

Spherical Hankel Function of the First Kind

$$h_n^{(1)}(x) \equiv \sqrt{\frac{\pi}{2x}}\,H_{n+1/2}^{(1)}(x) = j_n(x) + in_n(x),$$

where $H^{(1)}(x)$ is the HANKEL FUNCTION OF THE FIRST KIND and $j_n(x)$ and $n_n(x)$ are the SPHERICAL BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS. Explicitly, the first few are

$$\begin{aligned}h_0^{(1)}(x) &= \frac{1}{x}(\sin x - i\cos x) = -\frac{i}{x}e^{ix} \\ h_1^{(1)}(x) &= e^{ix}\left(-\frac{1}{x} - \frac{i}{x^2}\right) \\ h_2^{(1)}(x) &= e^{ix}\left(\frac{i}{x} - \frac{3}{x^2} - \frac{3i}{x^3}\right).\end{aligned}$$

References

Spherical Hankel Function of the Second Kind

$$h_n^{(2)}(x) \equiv \sqrt{\frac{\pi}{2x}}\,H_{n+1/2}^{(2)}(x) = j_n(x) - in_n(x),$$

where $H^{(2)}(x)$ is the HANKEL FUNCTION OF THE SECOND KIND and $j_n(x)$ and $n_n(x)$ are the SPHERICAL BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS. Explicitly, the first is

$$h_0^{(2)}(x) = \frac{1}{x}(\sin x + i\cos x) = \frac{i}{x}e^{-ix}.$$

References

Abramowitz, M. and Stegun, C. A. (Eds.). "Spherical Bessel Functions." §10.1 in *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, 9th printing.* New York: Dover, pp. 437–442, 1972.

Spherical Harmonic

The spherical harmonics $Y_l^m(\theta,\phi)$ are the angular portion of the solution to LAPLACE'S EQUATION in SPHERICAL COORDINATES where azimuthal symmetry is not present. Some care must be taken in identifying the notational convention being used. In the below equations, θ is taken as the azimuthal (longitudinal) coordinate, and ϕ as the polar (latitudinal) coordinate (opposite the notation of Arfken 1985).

$$Y_l^m(\theta,\phi) \equiv \sqrt{\frac{2l+1}{4\pi}\frac{(l-m)!}{(l+m)!}}P_l^m(\cos\phi)e^{im\theta}, \qquad (1)$$

where $m = -l, -1+1, \ldots, 0, \ldots, l$ and the normalization is chosen such that

$$\int_0^{2\pi}\int_0^{\pi} Y_l^m Y_{l'}^{m'\,*}\sin\phi\,d\phi\,d\theta = \int_0^{2\pi}\int_{-1}^{1} Y_l^m Y_{l'}^{m'\,*}\,d(\cos\phi)\,d\theta = \delta_{mm'}\delta_{ll'}, \qquad (2)$$

where δ_{mn} is the KRONECKER DELTA. Sometimes, the CONDON-SHORTLEY PHASE $(-1)^m$ is prepended to the definition of the spherical harmonics.

Integrals of the spherical harmonics are given by

$$\int Y_{l_1}^{m_1}Y_{l_2}^{m_2}Y_{l_3}^{m_3}\,d\Omega = \sqrt{\frac{(2l_1+1)(2l_2+1)(2l_3+1)}{4\pi}} \times \begin{pmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{pmatrix}\begin{pmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \end{pmatrix}, \qquad (3)$$

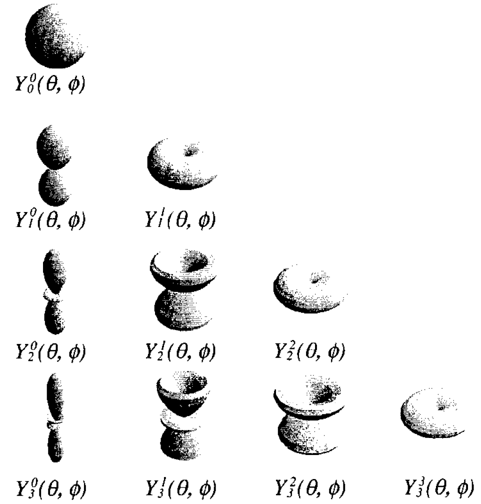
where $\begin{pmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \end{pmatrix}$ is a WIGNER 3j-SYMBOL (which is related to the CLEBSCH-GORDON COEFFICIENTS). The spherical harmonics obey

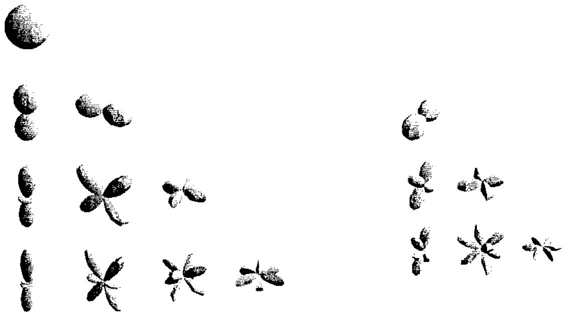
$$Y_l^{-l} = \frac{1}{2^l l!}\sqrt{\frac{(2l+1)!}{4\pi}}\sin^l\phi e^{-il\theta} \qquad (4)$$

$$Y_l^0 = \sqrt{\frac{2l+1}{4\pi}}P_l(\cos\phi) \qquad (5)$$

$$Y_l^{-m} = (-1)^m Y_l^{m*}, \qquad (6)$$

where $P_l(x)$ is a LEGENDRE POLYNOMIAL.





The above illustrations show $|Y_l^m(\theta,\phi)|$ (top) and $\Re[Y_l^m(\theta,\phi)]$ and $\Im[Y_l^m(\theta,\phi)]$ (bottom). The first few spherical harmonics are

$$Y_0^0 = \frac{1}{2}\frac{1}{\sqrt{\pi}}$$

$$Y_1^{-1} = \frac{1}{2}\sqrt{\frac{3}{2\pi}}\sin\phi\,e^{-i\theta}$$

$$Y_1^0 = \frac{1}{2}\sqrt{\frac{3}{\pi}}\cos\phi$$

$$Y_1^1 = -\frac{1}{2}\sqrt{\frac{3}{2\pi}}\sin\phi\,e^{i\theta}$$

$$Y_2^{-2} = \frac{1}{4}\sqrt{\frac{15}{2\pi}}\sin^2\phi\,e^{-2i\theta}$$

$$Y_2^{-1} = \frac{1}{2}\sqrt{\frac{15}{2\pi}}\sin\phi\cos\phi\,e^{-i\theta}$$

$$Y_2^0 = \frac{1}{4}\sqrt{\frac{5}{\pi}}(3\cos^2\phi - 1)$$

$$Y_2^1 = -\frac{1}{2}\sqrt{\frac{15}{2\pi}}\sin\phi\cos\phi\,e^{i\theta}$$

$$Y_2^2 = \frac{1}{4}\sqrt{\frac{15}{2\pi}}\sin^2\phi\,e^{2i\theta}$$

$$Y_3^{-3} = \frac{1}{8}\sqrt{\frac{35}{\pi}}\sin^3\phi\,e^{-3i\theta}$$

$$Y_3^{-2} = \frac{1}{4}\sqrt{\frac{105}{2\pi}}\sin^2\phi\cos\phi\,e^{-2i\theta}$$

$$Y_3^{-1} = \frac{1}{8}\sqrt{\frac{21}{\pi}}\sin\phi(5\cos^2\phi - 1)e^{-i\theta}$$

$$Y_3^0 = \frac{1}{4}\sqrt{\frac{7}{\pi}}(5\cos^3\phi - 3\cos\phi)$$

$$Y_3^1 = -\frac{1}{8}\sqrt{\frac{21}{\pi}}\sin\phi(5\cos^2\phi - 1)e^{i\theta}$$

$$Y_3^2 = \frac{1}{4}\sqrt{\frac{105}{2\pi}}\sin^2\phi\cos\phi\,e^{2i\theta}$$

$$Y_3^3 = -\frac{1}{8}\sqrt{\frac{35}{\pi}}\sin^3\phi\,e^{3i\theta}.$$

Written in terms of CARTESIAN COORDINATES,

$$e^{i\theta} = \frac{x+iy}{\sqrt{x^2+y^2}} \tag{7}$$

$$\phi = \sin^{-1}\left(\sqrt{\frac{x^2+y^2}{x^2+y^2+z^2}}\right) \tag{8}$$

$$= \cos^{-1}\left(\frac{z}{\sqrt{x^2+y^2+z^2}}\right), \tag{9}$$

so

$$Y_0^0 = \frac{1}{2}\frac{1}{\sqrt{\pi}} \tag{10}$$

$$Y_1^0 = \frac{1}{2}\sqrt{\frac{3}{\pi}}\frac{z}{\sqrt{x^2+y^2+z^2}} \tag{11}$$

$$Y_1^1 = -\frac{1}{2}\sqrt{\frac{3}{2\pi}}\frac{x+iy}{\sqrt{x^2+y^2+z^2}} \tag{12}$$

$$Y_2^0 = \frac{1}{4}\sqrt{\frac{5}{\pi}}\left(\frac{3z^2}{x^2+y^2+z^2}-1\right) \tag{13}$$

$$Y_2^1 = -\frac{1}{2}\sqrt{\frac{15}{2\pi}}\frac{z(x+iy)}{x^2+y^2+z^2} \tag{14}$$

$$Y_2^2 = \frac{1}{4}\sqrt{\frac{15}{2\pi}}\frac{(x+iy)^2}{x^2+y^2+z^2}. \tag{15}$$

These can be separated into their REAL and IMAGINARY PARTS

$$Y_l^{m\,s}(\theta,\phi) \equiv P_l^m(\cos\phi)\sin(m\theta) \tag{16}$$

$$Y_l^{m\,c}(\theta,\phi) \equiv P_l^m(\cos\phi)\cos(m\theta). \tag{17}$$

The ZONAL HARMONICS are defined to be those of the form

$$P_n^m(\cos\theta). \tag{18}$$

The TESSERAL HARMONICS are those of the form

$$\sin(m\phi)P_n^m(\cos\theta) \tag{19}$$

$$\cos(m\phi)P_n^m(\cos\theta) \tag{20}$$

for $n \neq m$. The SECTORIAL HARMONICS are of the form

$$\sin(m\phi)P_m^m(\cos\theta) \tag{21}$$

$$\cos(m\phi)P_m^m(\cos\theta). \tag{22}$$

The spherical harmonics form a COMPLETE ORTHONORMAL BASIS, so an arbitrary REAL function $f(\theta,\phi)$ can be expanded in terms of COMPLEX spherical harmonics

$$f(\theta,\phi) \equiv \sum_{l=0}^{\infty}\sum_{m=-1}^{l} A_l^m Y_l^m(\theta,\phi), \tag{23}$$

or REAL spherical harmonics

$$f(\theta,\phi) \equiv \sum_{l=0}^{\infty}\sum_{m=0}^{l}[C_l^m Y_l^{m\,c}(\theta,\phi)\sin(m\theta) + S_l^m Y_l^{m\,s}(\theta,\phi)]. \tag{24}$$

Spherical Harmonic Addition Theorem

A FORMULA also known as the LEGENDRE ADDITION THEOREM which is derived by finding GREEN'S FUNCTIONS for the SPHERICAL HARMONIC expansion and equating them to the generating function for LEGENDRE POLYNOMIALS. When γ is defined by

$$\cos\gamma \equiv \cos\theta_1\cos\theta_2 + \sin\theta_1\sin\theta_2\cos\phi_1 - \phi_2,$$

$$P_n(\cos\gamma) = \frac{4\pi}{2n+1}\sum_{m=-n}^{n}(-1)^m Y_m^n(\theta_1,\phi_1)Y_{-m}^n(\theta_2,\phi_2)$$

$$= \frac{4\pi}{2n+1}\sum_{m=-n}^{n} Y_m^n(\theta_1,\phi_1)Y_m^{n\,*}(\theta_2,\phi_2)$$

$$= P_n(\cos\theta_1)P_n(\cos\theta_2)$$

$$+2\sum_{m=-n}^{n}\frac{(n-m)!}{(n+m)!}P_m^n(\cos\theta_1)P_m^n(\cos\theta_2)\cos[m(\phi_1-\phi_2)].$$

Spherical Harmonic Closure Relations

The sum of the absolute squares of the SPHERICAL HARMONICS $Y_l^m(\theta,\phi)$ over all values of m is

$$\sum_{m=-l}^{l} |Y_l^m(\theta,\phi)|^2 = \frac{2l+1}{4\pi}.$$

The double sum over m and l is given by

$$\begin{aligned}\sum_{l=0}^{\infty}\sum_{m=-l}^{l} Y_l^m(\theta_1,\phi_1)Y_l^{m*}(\theta_2,\phi_2)\\ &= \frac{1}{\sin\theta_1}\delta(\theta_1-\theta_2)\delta(\phi_1-\phi_2)\\ &= \delta(\cos\theta_1-\cos\theta_2)\delta(\phi_1-\phi_2),\end{aligned}$$

where $\delta(x)$ is the DELTA FUNCTION.

Spherical Harmonic Tensor

A tensor defined in terms of the TENSORS which satisfy the DOUBLE CONTRACTION RELATION.

see also DOUBLE CONTRACTION RELATION, SPHERICAL HARMONIC

Spherical Helix

The TANGENT INDICATRIX of a CURVE OF CONSTANT PRECESSION is a spherical helix. The equation of a spherical helix on a SPHERE with RADIUS r making an ANGLE θ with the z-axis is

$$\begin{aligned}x(\psi) &= \tfrac{1}{2}r(1+\cos\theta)\cos\psi\\ &\quad -\tfrac{1}{2}r(1-\cos\theta)\cos\left(\frac{1+\cos\theta}{1-\cos\theta}\psi\right) \qquad (1)\\ y(\psi) &= \tfrac{1}{2}r(1+\cos\theta)\sin\psi\\ &\quad -\tfrac{1}{2}r(1-\cos\theta)\sin\left(\frac{1+\cos\theta}{1-\cos\theta}\psi\right) \qquad (2)\\ z(\psi) &= r\sin\theta\cos\left(\frac{\cos\theta}{1-\cos\theta}\psi\right). \qquad (3)\end{aligned}$$

The projection on the xy-plane is an EPICYCLOID with RADII

$$a = r\cos\theta \qquad (4)$$

$$b = r\sin^2(\tfrac{1}{2}\theta). \qquad (5)$$

see also HELIX, LOXODROME, SPHERICAL SPIRAL

Spherical Point System

How can n points be distributed on a SPHERE such that they maximize the minimum distance between any pair of points? This is FEJES TÓTH'S PROBLEM.

see also FEJES TÓTH'S PROBLEM

Spherical Polygon

A closed geometric figure on the surface of a SPHERE which is formed by the ARCS of GREAT CIRCLES. The spherical polygon is a generalization of the SPHERICAL TRIANGLE. If θ is the sum of the RADIAN ANGLES of a spherical polygon on a SPHERE of RADIUS r, then the AREA is

$$S = [\theta-(n-2)\pi]r^2.$$

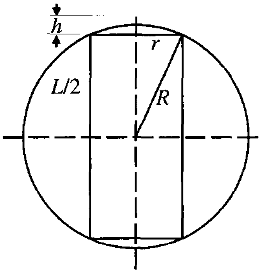
see also GREAT CIRCLE, SPHERICAL TRIANGLE

References

Beyer, W. H. *CRC Standard Mathematical Tables, 28th ed.* Boca Raton, FL: CRC Press, p. 131, 1987.

Spherical Ring

A SPHERE with a CYLINDRICAL HOLE cut so that the centers of the CYLINDER and SPHERE coincide, also called a NAPKIN RING.



The volume of the entire CYLINDER is

$$V_{\text{cyl}} = \pi LR^2, \qquad (1)$$

and the VOLUME of the upper segment is

$$V_{\text{seg}} = \tfrac{1}{6}\pi h(3R^2+h^2), \qquad (2)$$

where

$$R = \sqrt{r^2-\tfrac{1}{4}L^2} \qquad (3)$$

$$h = r-\tfrac{1}{2}L, \qquad (4)$$

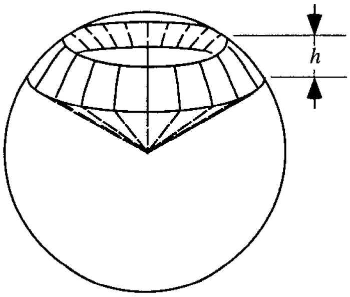
so the VOLUME removed upon drilling of a CYLINDRICAL hole is

$$\begin{aligned}V_{\text{rem}} &= V_{\text{cyl}}+2V_{\text{seg}} = \pi[LR^2+\tfrac{1}{3}h(3R^2+h^2)]\\ &= \pi(LR^2+hR^2+\tfrac{1}{3}h^3)\\ &= \pi[L(r^2-\tfrac{1}{4}L^2)+(r-\tfrac{1}{2}L)(r^2-\tfrac{1}{4}L^2)\\ &\quad +\tfrac{1}{3}(r-\tfrac{1}{2}L)^3]\\ &= \pi[Lr^2-\tfrac{1}{4}L^3+(r^3-\tfrac{1}{2}r^2L-\tfrac{1}{4}RL^2+\tfrac{1}{8}L^3)\\ &\quad +\tfrac{1}{3}(r^3-\tfrac{3}{2}r^2L+\tfrac{3}{4}rL^2-\tfrac{1}{8}L^3)]\\ &= \pi[\tfrac{4}{3}r^3+(1-\tfrac{1}{2}-\tfrac{1}{2})r^2L+(-\tfrac{1}{4}+\tfrac{1}{4})RL^2\\ &\quad +L^3(-\tfrac{1}{4}+\tfrac{1}{8}-\tfrac{1}{24})]\\ &= \tfrac{4}{3}\pi r^3-\tfrac{1}{6}\pi L^3 = \tfrac{1}{6}\pi(8r^3-L^3), \qquad (5)\end{aligned}$$

so

$$V_{\text{left}} = V_{\text{sphere}} - V_{\text{rem}} = \tfrac{4}{3}\pi r^3 - (\tfrac{4}{3}\pi r^3 - \tfrac{1}{6}\pi L^3) = \tfrac{1}{6}\pi L^3. \tag{6}$$

Spherical Sector



The VOLUME of a spherical sector, depicted above, is given by

$$V = \tfrac{2}{3}\pi R^2 h,$$

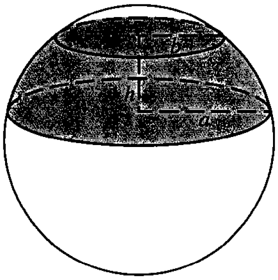
where h is the vertical height of the upper and lower curves.

see also CYLINDRICAL SEGMENT, SPHERE, SPHERICAL CAP, SPHERICAL SEGMENT, ZONE

References

Beyer, W. H. *CRC Standard Mathematical Tables, 28th ed.* Boca Raton, FL: CRC Press, p. 131, 1987.

Spherical Segment



A spherical segment is the solid defined by cutting a SPHERE with a pair of PARALLEL PLANES. It can be thought of as a SPHERICAL CAP with the top truncated, and so it corresponds to a SPHERICAL FRUSTUM. The surface of the spherical segment (excluding the bases) is called a ZONE.

Call the RADIUS of the SPHERE R and the height of the segment (the distance from the plane to the top of SPHERE) h. Let the RADII of the lower and upper bases be denoted a and b, respectively. Call the distance from the center to the start of the segment d, and the height from the bottom to the top of the segment h. Call the RADIUS parallel to the segment r, and the height above the center y. Then $r^2 = R^2 - y^2$,

$$\begin{aligned} V &= \int_d^{d+h} \pi r^2\,dy = \pi \int_d^{d+h} (R^2 - y^2)\,dy \\ &= \pi\left[R^2 y - \tfrac{1}{3}y^3\right]_d^{d+h} = \pi\{R^2 h - \tfrac{1}{3}[(d+h)^3 - d^3]\} \\ &= \pi[R^2 h - \tfrac{1}{3}(d^3 + 3d^2 h + 3h^2 d + h^3 - d^3)] \\ &= \pi(R^2 h - d^2 h - h^2 d - \tfrac{1}{3}h^3) \\ &= \pi h(R^2 - d^2 - hd - \tfrac{1}{3}h^2). \end{aligned} \tag{1}$$

Using

$$a^2 = R^2 - d^2 \tag{2}$$

$$b^2 = R^2 - (d+h)^2 = R^2 - d^2 - 2dh - h^2, \tag{3}$$

gives

$$a^2 + b^2 = 2R^2 - 2d^2 - 2dh - h^2 \tag{4}$$

$$R^2 - d^2 - dh = \tfrac{1}{2}(a^2 + b^2 + h^2), \tag{5}$$

so

$$\begin{aligned} V &= \pi h[\tfrac{1}{2}(a^2 + b^2 + h^2) - \tfrac{1}{3}h^2] = \pi h(\tfrac{1}{2}a^2 + \tfrac{1}{2}b^2 + \tfrac{1}{6}h^2) \\ &= \tfrac{1}{6}\pi h(3a^2 + 3b^2 + h^2). \end{aligned} \tag{6}$$

The surface area of the ZONE (which excludes the top and bottom bases) is given by

$$S = 2\pi R h. \tag{7}$$

References

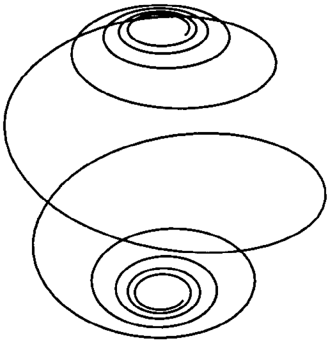
Beyer, W. H. *CRC Standard Mathematical Tables, 28th ed.* Boca Raton, FL: CRC Press, p. 130, 1987.

Spherical Shell

A generalization of an ANNULUS to 3-D. A spherical shell is the intersection of two concentric BALLS of differing RADII.

see also ANNULUS, BALL, CHORD, SPHERE, SPHERICAL HELIX

Spherical Spiral



The path taken by a ship which travels from the south pole to the north pole of a SPHERE while keeping a fixed (but not RIGHT) ANGLE with respect to the meridians. The curve has an infinite number of loops since the separation of consecutive revolutions gets smaller and smaller near the poles. It is given by the parametric equations

$$\begin{aligned} x &= \cos t \cos c \\ y &= \sin t \cos c \\ z &= -\sin c, \end{aligned}$$

where

$$c \equiv \tan^{-1}(at)$$

and a is a constant.

Lauwerier, H. "Spherical Spiral." In *Fractals: Endlessly Repeated Geometric Figures.* Princeton, NJ: Princeton University Press, pp. 64–66, 1991.

Spherical Symmetry

Let **A** and **B** be constant VECTORS. Define

$$Q \equiv 3(\mathbf{A} \cdot \hat{\mathbf{r}})(\mathbf{B} \cdot \hat{\mathbf{r}}) - \mathbf{A} \cdot \mathbf{B}.$$

Then the average of Q over a spherically symmetric surface or volume is

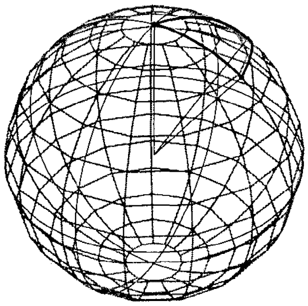
$$\langle Q \rangle = \left\langle 3\cos^2\theta - 1 \right\rangle (\mathbf{A} \cdot \mathbf{B}) = 0,$$

since $\left\langle 3\cos^2\theta - 1 \right\rangle = 0$ over the sphere.

Spherical Tessellation

see TRIANGULAR SYMMETRY GROUP

Spherical Triangle



A spherical triangle is a figure formed on the surface of a sphere by three great circular arcs intersecting pairwise in three vertices. The spherical triangle is the spherical analog of the planar TRIANGLE. Let a spherical triangle have ANGLES α, β, and γ and RADIUS r. Then the AREA of the spherical triangle is

$$K = r^2[(\alpha + \beta + \gamma) - \pi].$$

The sum of the angles of a spherical triangle is between 180° and 540°. The amount by which it exceeds 180° is called the SPHERICAL EXCESS and is denoted E or Δ.

The study of angles and distances of figures on a sphere is known as SPHERICAL TRIGONOMETRY.

see also COLUNAR TRIANGLE, GIRARD'S SPHERICAL EXCESS FORMULA, L'HUILIER'S THEOREM, SPHERICAL POLYGON, SPHERICAL TRIGONOMETRY

References

Abramowitz, M. and Stegun, C. A. (Eds.). *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, 9th printing.* New York: Dover, p. 79, 1972.

Spherical Trigonometry

Define a SPHERICAL TRIANGLE on the surface of a unit SPHERE, centered at a point O, with vertices A, B, and C. Define ANGLES $a \equiv \angle BOC$, $b \equiv \angle COA$, and $c \equiv \angle AOB$. Let the ANGLE between PLANES AOB and AOC be α, the ANGLE between PLANES BOC and AOB be β, and the ANGLE between PLANES BOC and AOC be γ. Define the VECTORS

$$\mathbf{a} \equiv \overrightarrow{OA} \tag{1}$$

$$\mathbf{b} \equiv \overrightarrow{OB} \tag{2}$$

$$\mathbf{c} \equiv \overrightarrow{OC}. \tag{3}$$

Then

$$\begin{aligned} (\hat{\mathbf{a}} \times \hat{\mathbf{b}}) \cdot (\hat{\mathbf{a}} \times \hat{\mathbf{c}}) &= (|\hat{\mathbf{a}}|\,|\hat{\mathbf{b}}| \sin c)(|\hat{\mathbf{a}}|\,|\hat{\mathbf{c}}| \sin b) \cos\alpha \\ &= \sin b \sin c \cos\alpha. \end{aligned} \tag{4}$$

Equivalently,

$$\begin{aligned} (\hat{\mathbf{a}} \times \hat{\mathbf{b}}) \cdot (\hat{\mathbf{a}} \times \hat{\mathbf{c}}) &= \hat{\mathbf{a}} \cdot [\hat{\mathbf{b}} \times (\hat{\mathbf{a}} \times \hat{\mathbf{c}})] \\ &= \hat{\mathbf{a}} \cdot [\hat{\mathbf{a}}(\hat{\mathbf{b}} \cdot \hat{\mathbf{c}}) - \hat{\mathbf{c}}(\hat{\mathbf{a}} \cdot \hat{\mathbf{b}})] \\ &= (\hat{\mathbf{b}} \cdot \hat{\mathbf{c}}) - (\hat{\mathbf{a}} \cdot \hat{\mathbf{c}})(\hat{\mathbf{a}} \cdot \hat{\mathbf{b}}) \\ &= \cos a - \cos c \cos b. \end{aligned} \tag{5}$$

Since these two expressions are equal, we obtain the identity

$$\cos a = \cos b \cos c + \sin b \sin c \cos\alpha \tag{6}$$

The identity

$$\begin{aligned} \sin\alpha &= \frac{|(\hat{\mathbf{a}} \times \hat{\mathbf{b}}) \times (\hat{\mathbf{a}} \times \hat{\mathbf{c}})|}{|\hat{\mathbf{a}} \times \hat{\mathbf{b}}||\hat{\mathbf{a}} \times \hat{\mathbf{c}}|} = -\frac{|\hat{\mathbf{a}}[\hat{\mathbf{b}}, \hat{\mathbf{a}}, \hat{\mathbf{c}}] + \hat{\mathbf{b}}[\hat{\mathbf{a}}, \hat{\mathbf{a}}, \hat{\mathbf{c}}]|}{\sin b \sin c} \\ &= \frac{[\hat{\mathbf{a}}, \hat{\mathbf{b}}, \hat{\mathbf{c}}]}{\sin b \sin c}, \end{aligned} \tag{7}$$

where $[\mathbf{a},\mathbf{b},\mathbf{c}]$ is the SCALAR TRIPLE PRODUCT, gives a spherical analog of the LAW OF SINES,

$$\frac{\sin\alpha}{\sin a}=\frac{\sin\beta}{\sin b}=\frac{\sin\gamma}{\sin c}=\frac{6\operatorname{Vol}(OABC)}{\sin a\sin b\sin c}, \tag{8}$$

where $\operatorname{Vol}(OABC)$ is the VOLUME of the TETRAHEDRON. From (7) and (8), it follows that

$$\sin a\cos\beta=\cos b\sin c-\sin b\cos c\cos\alpha \tag{9}$$

$$\cos a\cos\gamma=\sin a\cot b-\sin\gamma\cot\beta. \tag{10}$$

These are the fundamental equalities of spherical trigonometry.

There are also spherical analogs of the LAW OF COSINES for the sides of a spherical triangle,

$$\cos a=\cos b\cos c+\sin b\sin c\cos A \tag{11}$$

$$\cos b=\cos c\cos a+\sin c\sin a\cos B \tag{12}$$

$$\cos c=\cos a\cos b+\sin a\sin b\cos C, \tag{13}$$

and the angles of a spherical triangle,

$$\cos A=-\cos B\cos C+\sin B\sin C\cos a \tag{14}$$

$$\cos B=-\cos C\cos A+\sin C\sin A\cos b \tag{15}$$

$$\cos C=-\cos A\cos B+\sin A\sin B\cos c \tag{16}$$

(Beyer 1987), as well as the LAW OF TANGENTS

$$\frac{\tan[\frac{1}{2}(a-b)]}{\tan[\frac{1}{2}(a+b)]}=\frac{\tan[\frac{1}{2}(A-B)]}{\tan[\frac{1}{2}(A+B)]}. \tag{17}$$

Let

$$s\equiv\tfrac{1}{2}(a+b+c) \tag{18}$$

$$S\equiv\tfrac{1}{2}(A+B+C), \tag{19}$$

then the half-angle formulas are

$$\tan(\tfrac{1}{2}A)=\frac{k}{\sin(s-a)} \tag{20}$$

$$\tan(\tfrac{1}{2}B)=\frac{k}{\sin(s-b)} \tag{21}$$

$$\tan(\tfrac{1}{2}C)=\frac{k}{\sin(s-c)}, \tag{22}$$

where

$$k^2=\frac{\sin(s-a)\sin(s-b)\sin(s-c)}{\sin s}=\tan^2 r, \tag{23}$$

and the half-side formulas are

$$\tan(\tfrac{1}{2}a)=K\cos(S-A) \tag{24}$$

$$\tan(\tfrac{1}{2}b)=K\cos(S-B) \tag{25}$$

$$\tan(\tfrac{1}{2}c)=K\cos(S-C), \tag{26}$$

where

$$K^2=-\frac{\cos S}{\cos(S-A)\cos(S-B)\cos(S-C)}=\tan^2 R, \tag{27}$$

where R is the RADIUS of the SPHERE on which the spherical triangle lies.

Additional formulas include the HAVERSINE formulas

$$\operatorname{hav}a=\operatorname{hav}(b-c)+\sin b\sin c\sin(s-c) \tag{28}$$

$$\operatorname{hav}A=\frac{\sin(s-b)\sin(s-c)}{\sin b\sin c} \tag{29}$$

$$=\frac{\operatorname{hav}a-\operatorname{hav}(b-c)}{\sin b\sin c} \tag{30}$$

$$=\operatorname{hav}[\pi-(B+C)]+\sin B\sin C\operatorname{hav}a, \tag{31}$$

GAUSS'S FORMULAS

$$\frac{\sin[\frac{1}{2}(a-b)]}{\sin(\frac{1}{2}c)}=\frac{\sin[\frac{1}{2}(A-B)]}{\cos(\frac{1}{2}C)} \tag{32}$$

$$\frac{\sin[\frac{1}{2}(a+b)]}{\sin(\frac{1}{2}c)}=\frac{\cos[\frac{1}{2}(A-B)]}{\sin(\frac{1}{2}C)} \tag{33}$$

$$\frac{\cos[\frac{1}{2}(a-b)]}{\cos(\frac{1}{2}c)}=\frac{\sin[\frac{1}{2}(A+B)]}{\cos(\frac{1}{2}C)} \tag{34}$$

$$\frac{\cos[\frac{1}{2}(a+b)]}{\cos(\frac{1}{2}c)}=\frac{\cos[\frac{1}{2}(A+B)]}{\sin(\frac{1}{2}C)}, \tag{35}$$

and NAPIER'S ANALOGIES

$$\frac{\sin[\frac{1}{2}(A-B)]}{\sin[\frac{1}{2}(A+B)]}=\frac{\tan[\frac{1}{2}(a-b)]}{\tan(\frac{1}{2}c)} \tag{36}$$

$$\frac{\cos[\frac{1}{2}(A-B)]}{\cos[\frac{1}{2}(A+B)]}=\frac{\tan[\frac{1}{2}(a+b)]}{\tan(\frac{1}{2}c)} \tag{37}$$

$$\frac{\sin[\frac{1}{2}(a-b)]}{\sin[\frac{1}{2}(a+b)]}=\frac{\tan[\frac{1}{2}(A-B)]}{\cot(\frac{1}{2}C)} \tag{38}$$

$$\frac{\cos[\frac{1}{2}(a-b)]}{\cos[\frac{1}{2}(a+b)]}=\frac{\tan[\frac{1}{2}(A+B)]}{\cot(\frac{1}{2}C)} \tag{39}$$

(Beyer 1987).

Spherical Vector Harmonic

see VECTOR SPHERICAL HARMONIC

Spheroid

A spheroid is an ELLIPSOID

$$\frac{r^2\cos^2\theta\sin^2\phi}{a^2}+\frac{r^2\sin^2\theta\sin^2\phi}{b^2}+\frac{r^2\cos^2\phi}{c^2}=1 \quad (1)$$

with two SEMIMAJOR AXES equal. Orient the ELLIPSE so that the a and b axes are equal, then

$$\frac{r^2\cos^2\theta\sin^2\phi}{a^2}+\frac{r^2\sin^2\theta\sin^2\phi}{a^2}+\frac{r^2\cos^2\phi}{c^2}=1 \quad (2)$$

$$\frac{r^2\sin^2\phi}{a^2}+\frac{r^2\cos^2\phi}{c^2}=1, \quad (3)$$

where a is the equatorial RADIUS and c is the polar RADIUS. Here ϕ is the colatitude, so take $\delta\equiv\pi/2-\phi$ to express in terms of latitude.

$$\frac{r^2\cos^2\delta}{a^2}+\frac{r^2\sin^2\delta}{c^2}=1. \quad (4)$$

Rewriting $\cos^2\delta=1-\sin^2\delta$ gives

$$\frac{r^2}{a^2}+r^2\sin^2\delta\left(\frac{1}{c^2}-\frac{1}{a^2}\right)=1 \quad (5)$$

$$r^2\left(1+a^2\sin^2\delta\frac{a^2-c^2}{c^2a^2}\right)$$
$$=r^2\left(1+\sin^2\delta\frac{a^2-c^2}{c^2}\right)=a^2, \quad (6)$$

so

$$r=a\left(1+\sin^2\delta\frac{a^2-c^2}{c^2}\right)^{-1/2}. \quad (7)$$

If $a>c$, the spheroid is OBLATE. If $a<c$, the spheroid is PROLATE. If $a=c$, the spheroid degenerates to a SPHERE.

see also DARWIN-DE SITTER SPHEROID, ELLIPSOID, OBLATE SPHEROID, PROLATE SPHEROID

Spheroidal Harmonic

A spheroidal harmonic is a special case of the ELLIPSOIDAL HARMONIC which satisfies the differential equation

$$\frac{d}{dx}\left[(1-x^2)\frac{dS}{dx}\right]+\left(\lambda-c^2x^2-\frac{m^2}{1-x^2}\right)S=0$$

on the interval $-1\le x\le 1$.

Spheroidal Wavefunction

Whittaker and Watson (1990, p. 403) define the internal and external spheroidal wavefunctions as

$$S_{mn}^{(1)}=2\pi\frac{(n-m)!}{(n+m)!}P_n^m(ir)P_n^m(\cos\theta)\begin{matrix}\cos\\ \sin\end{matrix}(m\phi)$$

$$S_{mn}^{(2)}=2\pi\frac{(n-m)!}{(n+m)!}Q_n^m(ir)Q_n^m(\cos\theta)\begin{matrix}\cos\\ \sin\end{matrix}(m\phi).$$

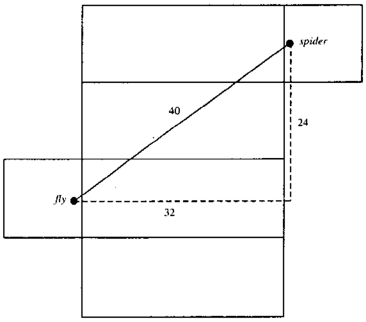
Spider and Fly Problem



In a rectangular room (a CUBOID) with dimensions 30′ × 12′ × 12′, a spider is located in the middle of one 12′ × 12′ wall one foot away from the ceiling. A fly is in the middle of the opposite wall one foot away from the floor. If the fly remains stationary, what is the shortest distance the spider must crawl to capture the fly? The answer, 40′, can be obtained by "flattening" the walls as illustrated above.

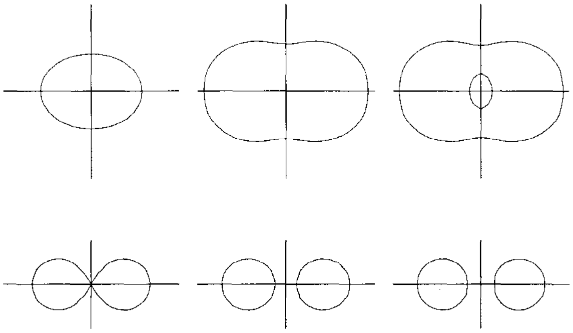
Spiric Section



A curve with Cartesian equation

$$(r^2 - a^2 + c^2 + x^2 + y^2) = 4r^2(x^2 + c^2).$$

Around 150 BC, Menaechmus constructed CONIC SECTIONS by cutting a CONE by a PLANE. Two hundred years later, the Greek mathematician Perseus investigated the curves obtained by cutting a TORUS by a PLANE which is PARALLEL to the line through the center of the HOLE of the TORUS (MacTutor).

In the FORMULA of the curve given above, the TORUS is formed from a CIRCLE of RADIUS a whose center is rotated along a CIRCLE of RADIUS r. The value of c gives the distance of the cutting PLANE from the center of the TORUS.

When $c = 0$, the curve consists of two CIRCLES of RADIUS a whose centers are at $(r, 0)$ and $(-r, 0)$. If $c = r + a$, the curve consists of one point (the origin), while if $c > r + a$, no point lies on the curve. The above curves have $(a, b, r) = (3, 4, 2)$, (3, 1, 2) (3, 0.8, 2), (3, 1, 4), (3, 1, 4.5), and (3, 0, 4.5).

References

Spirograph

A HYPOTROCHOID generated by a fixed point on a CIRCLE rolling inside a fixed CIRCLE. It has parametric equations,

$$x = (R + r)\cos\theta - (r + \rho)\cos\left(\frac{R + r}{r}\theta\right) \qquad (1)$$

$$y = (R + r)\sin\theta - (r + \rho)\sin\left(\frac{R + r}{r}\theta\right), \qquad (2)$$

where R is the radius of the fixed circle, r is the radius of the rotating circle, and ρ is the offset of the edge of the rotating circle. The figure closes only if R, r, and ρ are RATIONAL. The equations can also be written

$$x = x_0[m\cos t + a\cos(nt)] - y_0[m\sin t - a\sin(nt)] \qquad (3)$$

$$y = y_0[m\cos t + a\cos(nt)] + x_0[m\sin t - a\sin(nt)], \qquad (4)$$

where the outer wheel has radius 1, the inner wheel a radius p/q, the pen is placed a units from the center, the beginning is at θ radians above the x-axis, and

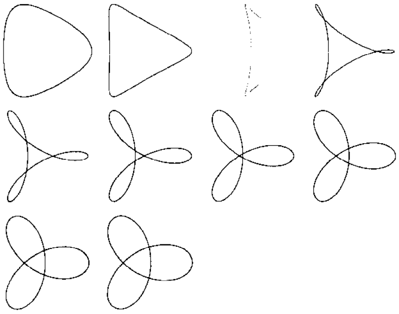
$$m \equiv \frac{q-p}{q} \qquad (5)$$

$$n \equiv \frac{q-p}{p} \qquad (6)$$

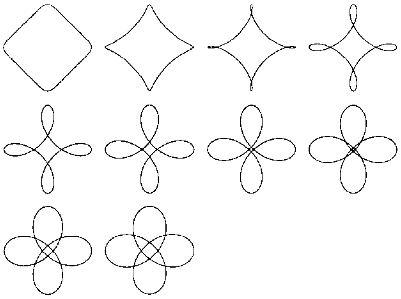
$$x_0 \equiv \cos\theta \qquad (7)$$

$$y_0 \equiv \sin\theta. \qquad (8)$$

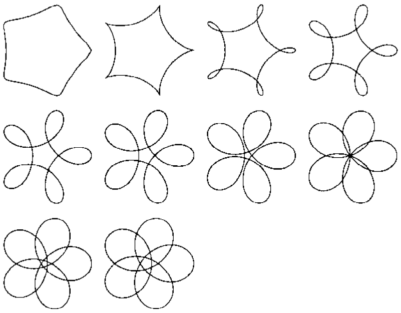
The following curves are for $a = i/10$, with $i = 1, 2, \ldots, 10$, and $\theta = 0$.



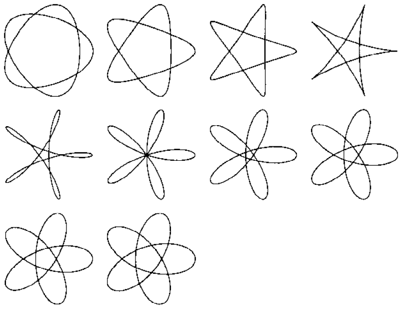
$(p,q) = (1,3)$



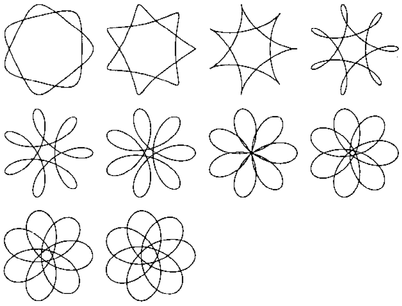
$(p,q) = (1,4)$



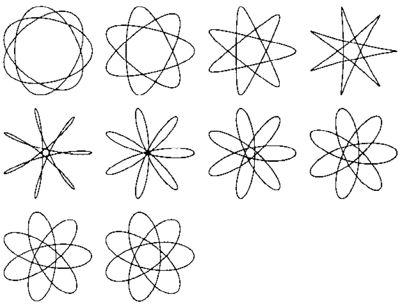
$(p,q) = (1,5)$



$(p,q) = (2,5)$

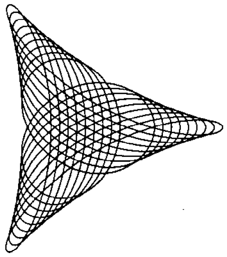


$(p,q) = (2,7)$



$(p,q) = (3,7)$

Additional attractive designs such as the following can also be made by superposing individual spirographs.



see also EPITROCHOID, HYPOTROCHOID, MAURER ROSE, SPIROLATERAL

Spirolateral

A figure formed by taking a series of steps of length 1, 2, ..., n, with an angle θ turn after each step. The symbol for a spirolateral is $^{a_1,\ldots,a_k}n_\theta$, where the a_is indicate that turns are in the $-\theta$ direction for these steps.

Spun Knot

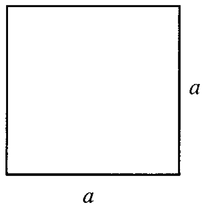
A 3-D KNOT spun about a plane in 4-D. Unlike SUSPENDED KNOTS, spun knots are smoothly embedded at the poles.

see also SUSPENDED KNOT, TWIST-SPUN KNOT

Squarable

An object which can be constructed by SQUARING is called squarable.

Square



The term square is sometimes used to mean SQUARE NUMBER. When used in reference to a geometric figure, however, it means a convex QUADRILATERAL with four equal sides at RIGHT ANGLES to each other, illustrated above.

The PERIMETER of a square with side length a is

$$L = 4a \tag{1}$$

and the AREA is

$$A = a^2. \tag{2}$$

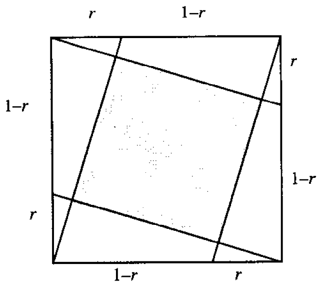
The INRADIUS r, CIRCUMRADIUS R, and AREA A can be computed directly from the formulas for a general regular POLYGON with side length a and $n = 4$ sides,

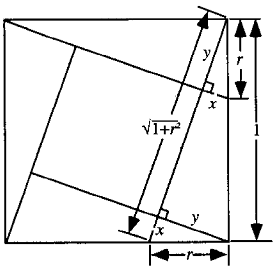
$$r = \tfrac{1}{2}a\cot\left(\frac{\pi}{4}\right) = \tfrac{1}{2}a \tag{3}$$

$$R = \tfrac{1}{2}a\csc\left(\frac{\pi}{4}\right) = \tfrac{1}{2}\sqrt{2}\,a \tag{4}$$

$$A = \tfrac{1}{4}na^2\cot\left(\frac{\pi}{4}\right) = a^2. \tag{5}$$

The length of the DIAGONAL of the UNIT SQUARE is $\sqrt{2}$, sometimes known as PYTHAGORAS'S CONSTANT.





The AREA of a square inscribed inside a UNIT SQUARE as shown in the above diagram can be found as follows. Label x and y as shown, then

$$x^2 + y^2 = r^2 \tag{6}$$

$$(\sqrt{1+r^2} - x)^2 + y^2 = 1. \tag{7}$$

Plugging (6) into (7) gives

$$(\sqrt{1+r^2} - x)^2 + (r^2 - x^2) = 1. \tag{8}$$

Expanding

$$x^2 - 2x\sqrt{1+r^2} + 1 + r^2 + r^2 - x^2 = 1 \tag{9}$$

and solving for x gives

$$x = \frac{r^2}{\sqrt{1+r^2}}. \tag{10}$$

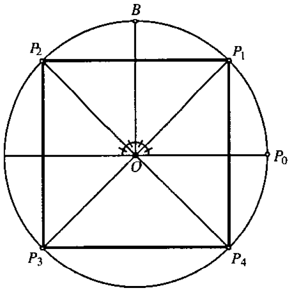
Plugging in for y yields

$$y = \sqrt{r^2 - x^2} = \frac{r}{\sqrt{1+r^2}}. \tag{11}$$

The area of the shaded square is then

$$A = (\sqrt{1+r^2} - x - y)^2 = \frac{(1-r)^2}{1+r^2} \tag{12}$$

(Detemple and Harold 1996).



Square

The STRAIGHTEDGE and COMPASS construction of the square is simple. Draw the line OP_0 and construct a circle having OP_0 as a radius. Then construct the perpendicular OB through O. Bisect P_0OB and $P_0'OB$ to locate P_1 and P_2, where P_0' is opposite P_0. Similarly, construct P_3 and P_4 on the other SEMICIRCLE. Connecting $P_1P_2P_3P_4$ then gives a square.

As shown by Schnirelmann, a square can be INSCRIBED in any closed convex planar curve (Steinhaus 1983). A square can also be CIRCUMSCRIBED about any closed curve (Steinhaus 1983).

An infinity of points in the interior of a square are known whose distances from three of the corners of a square are RATIONAL NUMBERS. Calling the distances a, b, and c where s is the side length of the square, these solutions satisfy

$$(s^2 + b^2 - a^2)^2 + (s^2 + b^2 - c^2)^2 = (2bs)^2 \tag{13}$$

(Guy 1994). In this problem, one of a, b, c, and s is DIVISIBLE by 3, one by 4, and one by 5. It is not known if there are points having distances from *all four* corners RATIONAL, but such a solution requires the additional condition

$$a^2 + c^2 = b^2 + d^2. \tag{14}$$

In this problem, s is DIVISIBLE by 4 and a, b, c, and d are ODD. If s is not DIVISIBLE by 3 (5), then two of a, b, c, and d are DIVISIBLE by 3 (5) (Guy 1994).

Square Bracket Polynomial

A POLYNOMIAL which is not necessarily an invariant of a LINK. It is related to the DICHROIC POLYNOMIAL. It is defined by the SKEIN RELATIONSHIP

$$B_{L_+} = q^{-1/2} v B_{L_0} + B_{L_\infty}, \tag{1}$$

and satisfies

$$B_{\text{unknot}} = q^{1/2} \tag{2}$$

and

$$B_{L\cup\text{unknot}} = q^{1/2} B_L. \tag{3}$$

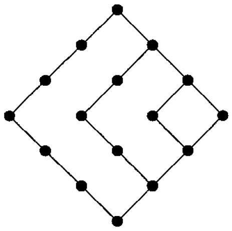
Square Matrix

A MATRIX for which horizontal and vertical dimensions are the same (i.e., an $n \times n$ MATRIX).

see also MATRIX

Square Number



A FIGURATE NUMBER of the form $m = n^2$, where n is an INTEGER. A square number is also called a PERFECT SQUARE. The first few square numbers are 1, 4, 9, 25, 36, 49, ... (Sloane's A000290). The GENERATING FUNCTION giving the square numbers is

$$\frac{x(x+1)}{(1-x)^3}=x+4x^2+9x^3+16x^4+\ldots. \tag{1}$$

The kth nonsquare number a_k is given by

$$a_n=n+\left\lfloor\tfrac{1}{2}+\sqrt{n}\right\rfloor, \tag{2}$$

where $\lfloor x\rfloor$ is the FLOOR FUNCTION, and the first few are 2, 3, 5, 6, 7, 8, 10, 11, ... (Sloane's A000037).

The only numbers which are simultaneously square and PYRAMIDAL (the CANNONBALL PROBLEM) are $P_1 = 1$ and $P_{24} = 4900$, corresponding to $S_1 = 1$ and $S_{70} = 4900$ (Dickson 1952, p. 25; Ball and Coxeter 1987, p. 59; Ogilvy 1988), as conjectured by Lucas (1875, 1876) and proved by Watson (1918). The CANNONBALL PROBLEM is equivalent to solving the DIOPHANTINE EQUATION

$$y^2=\tfrac{1}{6}x(x+1)(2x+1) \tag{3}$$

(Guy 1994, p. 147).

The only numbers which are square and TETRAHEDRAL are $Te_1 = 1$, $Te_2 = 4$, and $Te_{48} = 19600$ (giving $S_1 = 1$, $S_2 = 4$, and $S_{140} = 19600$), as proved by Meyl (1878; cited in Dickson 1952, p. 25; Guy 1994, p. 147). In general, proving that only certain numbers are simultaneously figurate in two different ways is far from elementary.

To find the possible last digits for a square number, write $n = 10a+b$ for the number written in decimal NOTATION as ab_{10} ($a, b = 0, 1, \ldots, 9$). Then

$$n^2 = 100a^2 + 20ab + b^2, \tag{4}$$

so the last digit of n^2 is the same as the last digit of b^2. The following table gives the last digit of b^2 for $b = 0, 1, \ldots, 9$. As can be seen, the last digit can be only 0, 1, 4, 5, 6, or 9.

0	1	2	3	4	5	6	7	8	9
0	1	4	9	_6	_5	_6	_9	_4	_1

We can similarly examine the allowable last two digits by writing abc_{10} as

$$n = 100a + 10b + c, \tag{5}$$

so

$$\begin{aligned} n^2 &= (100a + 10b + c)^2 \\ &= 10^4a^2 + 2(1000ab + 100ac + 10bc) + 100b^2 + c^2 \\ &= (10^4a^2 + 2000ab + 100ac + 100b^2) + 20bc + c^2, \end{aligned} \tag{6}$$

so the last two digits are given by $20bc + c^2 = c(20b+c)$. But since the last digit must be 0, 1, 4, 5, 6, or 9, the following table exhausts all possible last two digits.

c	*b*									
	0	1	2	3	4	5	6	7	8	9
1	01	21	41	61	81	_01	_21	_41	_61	_81
4	16	96	_76	_56	_36	_16	_96	_76	_56	_36
5	25	_25	_25	_25	_25	_25	_25	_25	_25	_25
6	36	_56	_76	_96	_16	_36	_56	_76	_96	_16
9	81	_61	_41	_21	_01	_81	_61	_41	_21	_01

The only possibilities are 00, 01, 04, 09, 16, 21, 24, 25, 29, 36, 41, 44, 49, 56, 61, 64, 69, 76, 81, 84, 89, and 96, which can be summarized succinctly as 00, *e*1, *e*4, 25, *o*6, and *e*9, where *e* stands for an EVEN NUMBER and *o* for an ODD NUMBER. Additionally, unless the sum of the digits of a number is 1, 4, 7, or 9, it cannot be a square number.

The following table gives the possible residues mod n for square numbers for $n = 1$ to 20. The quantity $s(n)$ gives the number of distinct residues for a given n.

n	$s(n)$	$x^2 \pmod{n}$
2	2	0, 1
3	2	0, 1
4	2	0, 1
5	3	0, 1, 4
6	4	0, 1, 3, 4
7	4	0, 1, 2, 4
8	3	0, 1, 4
9	4	0, 1, 4, 7
10	6	0, 1, 4, 5, 6, 9
11	6	0, 1, 3, 4, 5, 9
12	4	0, 1, 4, 9
13	7	0, 1, 3, 4, 9, 10, 12
14	8	0, 1, 2, 4, 7, 8, 9, 11
15	6	0, 1, 4, 6, 9, 10
16	4	0, 1, 4, 9
17	9	0, 1, 2, 4, 8, 9, 13, 15, 16
18	8	0, 1, 4, 7, 9, 10, 13, 16
19	10	0, 1, 4, 5, 6, 7, 9, 11, 16, 17
20	6	0, 1, 4, 5, 9, 16

In general, the ODD squares are congruent to 1 (mod 8) (Conway and Guy 1996). Stangl (1996) gives an explicit formula by which the number of squares $s(n)$ in $\mathbb{Z}_n$ (i.e., mod n) can be calculated. Let p be an ODD PRIME. Then $s(n)$ is the MULTIPLICATIVE FUNCTION given by

$$s(2) = 2 \tag{7}$$

$$s(p) = \tfrac{1}{2}(p+1) \qquad (p \neq 2) \tag{8}$$

$$s(p^2) = \tfrac{1}{2}(p^2 - p + 2) \qquad (p \neq 2) \tag{9}$$

$$s(2^n) = \begin{cases} \frac{1}{3}(2^{n-1} + 4) & \text{for } n \text{ even} \\ \frac{1}{3}(2^{n-1} + 5) & \text{for } n \text{ odd} \end{cases} \tag{10}$$

$$s(p^n) = \begin{cases} \frac{p^{n+1}+p+2}{2(p+1)} & \text{for } n \geq 3 \text{ even} \\ \frac{p^{n+1}+2p+1}{2(p+1)} & \text{for } n \geq 3 \text{ odd.} \end{cases} \tag{11}$$

$s(n)$ is related to the number $q(n)$ of QUADRATIC RESIDUES in $\mathbb{Z}_n$ by

$$q(p^n) = s(p^n) - s(p^{n-2}) \tag{12}$$

for $n \geq 3$ (Stangl 1996).

For a perfect square n, $(n/p) = 0$ or 1 for all ODD PRIMES $p < n$ where (n/p) is the LEGENDRE SYMBOL. A number n which is not a perfect square but which satisfies this relationship is called a PSEUDOSQUARE.

The minimum number of squares needed to represent the numbers 1, 2, 3, ... are 1, 2, 3, 1, 2, 3, 4, 2, 1, 2, ... (Sloane's A002828), and the number of distinct ways to represent the numbers 1, 2, 3, ... in terms of squares are 1, 1, 1, 2, 2, 2, 2, 3, 4, 4, ... (Sloane's A001156). A brute-force algorithm for enumerating the square permutations of n is repeated application of the GREEDY ALGORITHM. However, this approach rapidly becomes impractical since the number of representations grows extremely rapidly with n, as shown in the following table.

n	Square Partitions
10	4
50	104
100	1116
150	6521
200	27482

Every POSITIVE integer is expressible as a SUM of (at most) $g(2) = 4$ square numbers (WARING'S PROBLEM). (Actually, the basis set is $\{0, 1, 4, 9, 16, 25, 36, 64, 81, 100, \ldots\}$, so 49 need never be used.) Furthermore, an infinite number of n require four squares to represent them, so the related quantity $G(2)$ (the least INTEGER n such that every POSITIVE INTEGER beyond a certain point requires $G(2)$ squares) is given by $G(2) = 4$.

Numbers expressible as the sum of two squares are those whose PRIME FACTORS are of the form $4k - 1$ taken to an EVEN POWER. Numbers expressible as the sum of three squares are those not of the form $4^k(8l + 7)$ for $k, l \geq 0$. The following table gives the first few numbers which require $N = 1$, 2, 3, and 4 squares to represent them as a sum.

N	Sloane	Numbers
1	000290	1, 4, 9, 16, 25, 36, 49, 64, 81, ...
2	000415	2, 5, 8, 10, 13, 17, 18, 20, 26, 29, ...
3	000419	3, 6, 11, 12, 14, 19, 21, 22, 24, 27, ...
4	004215	7, 15, 23, 28, 31, 39, 47, 55, 60, 63, ...

The FERMAT $4n + 1$ THEOREM guarantees that every PRIME of the form $4n+1$ is a sum of two SQUARE NUMBERS in only one way.

There are only 31 numbers which cannot be expressed as the sum of *distinct* squares: 2, 3, 6, 7, 8, 11, 12, 15, 18, 19, 22, 23, 24, 27, 28, 31, 32, 33, 43, 44, 47, 48, 60, 67, 72, 76, 92, 96, 108, 112, 128 (Sloane's A001422; Guy 1994). All numbers > 188 can be expressed as the sum of at most five distinct squares, and only

$$124 = 1 + 4 + 9 + 25 + 36 + 49 \tag{13}$$

and

$$188 = 1 + 4 + 9 + 25 + 49 + 100 \tag{14}$$

require six distinct squares (Bohman *et al.* 1979; Guy 1994, p. 136). In fact, 188 can also be represented using seven distinct squares:

$$188 = 1 + 4 + 9 + 25 + 36 + 49 + 64. \tag{15}$$

The following table gives the numbers which can be represented in W different ways as a sum of S squares. For example,

$$50 = 1^2 + 7^2 = 5^2 + 5^2$$

can be represented in two ways ($W = 2$) by two squares ($S = 2$).

S	W	Sloane	Numbers
1	1	000290	1, 4, 9, 16, 25, 36, 49, 64, 81, 100, ...
2	1	025284	2, 5, 8, 10, 13, 17, 18, 20, 25, 26, 29, ...
2	2	025285	50, 65, 85, 125, 130, 145, 170, 185, ...
3	1	025321	3, 6, 9, 11, 12, 14, 17, 18, 19, 21, 22, ...
3	2	025322	27, 33, 38, 41, 51, 57, 59, 62, 69, 74, ...
3	3	025323	54, 66, 81, 86, 89, 99, 101, 110, 114, ...
3	4	025324	129, 134, 146, 153, 161, 171, 189, ...
4	1	025357	4, 7, 10, 12, 13, 15, 16, 18, 19, 20, ...
4	2	025358	31, 34, 36, 37, 39, 43, 45, 47, 49, ...
4	3	025359	28, 42, 55, 60, 66, 67, 73, 75, 78, ...
4	4	025360	52, 58, 63, 70, 76, 84, 87, 91, 93, ...

The number of INTEGERS $< x$ which are squares or sums of two squares is

$$N(x) \sim kx(\ln x)^{-1/2}, \tag{16}$$

where

$$k = \sqrt{\frac{1}{2} \prod_{\substack{r=4n+3 \\ r \text{ prime}}} (1 - r^{-2})^{-1}} \tag{17}$$

(Landau 1908; Le Lionnais 1983, p. 31). The product of four distinct NONZERO INTEGERS in ARITHMETIC PROGRESSION is square only for $(-3, -1, 1, 3)$, giving $(-3)(-1)(1)(3) = 9$ (Le Lionnais 1983, p. 53). It is possible to have three squares in ARITHMETIC PROGRESSION, but not four (Dickson 1952, pp. 435–440). If these numbers are r^2, s^2, and t^2, there are POSITIVE INTEGERS p and q such that

$$r = |p^2 - 2pq - q^2| \tag{18}$$

$$s = p^2 + q^2 \tag{19}$$

$$t = p^2 + 2pq - q^2, \tag{20}$$

where $(p, q) = 1$ and one of r, s, or t is EVEN (Dickson 1952, pp. 437–438). Every three-term progression of squares can be associated with a PYTHAGOREAN TRIPLE (X, Y, Z) by

$$X = \tfrac{1}{2}(r + t) \tag{21}$$

$$Y = \tfrac{1}{2}(t - r) \tag{22}$$

$$Z = s \tag{23}$$

(Robertson 1996).

CATALAN'S CONJECTURE states that 8 and 9 (2^3 and 3^2) are the only consecutive POWERS (excluding 0 and 1), i.e., the only solution to CATALAN'S DIOPHANTINE PROBLEM. This CONJECTURE has not yet been proved or refuted, although R. Tijdeman has proved that there can be only a finite number of exceptions should the CONJECTURE not hold. It is also known that 8 and 9 are the only consecutive CUBIC and square numbers (in either order).

A square number can be the concatenation of two squares, as in the case $16 = 4^2$ and $9 = 3^2$ giving $169 = 13^2$.

It is conjectured that, other than 10^{2n}, 4×10^{2n} and 9×10^{2n}, there are only a FINITE number of squares n^2 having exactly two distinct NONZERO DIGITS (Guy 1994, p. 262). The first few such n are 4, 5, 6, 7, 8, 9, 11, 12, 15, 21, ... (Sloane's A016070), corresponding to n^2 of 16, 25, 36, 49, 64, 81, 121, ... (Sloane's A016069).

The following table gives the first few numbers which, when squared, give numbers composed of only certain digits. The only known square number composed only of the digits 7, 8, and 9 is 9. Vardi (1991) considers numbers composed only of the square digits: 1, 4, and 9.

Digits	Sloane	n, n^2
1, 2, 3	030175	1, 11, 111, 36361, 363639, ...
	030174	1, 121, 12321, 1322122321, ...
1, 4, 6	027677	1, 2, 4, 8, 12, 31, 38, 108, ...
	027676	1, 4, 16, 64, 144, 441, 1444, ...
1, 4, 9	027675	1, 2, 3, 7, 12, 21, 38, 107, ...
	006716	1, 4, 9, 49, 144, 441, 1444, 11449, ...
2, 4, 8	027679	2, 22, 168, 478, 2878, 210912978, ...
	027678	4, 484, 28224, 228484, 8282884, ...
4, 5, 6	030177	2, 8, 216, 238, 258, 738, 6742, ...
	030176	4, 64, 46656, 56644, 66564, ...

BROWN NUMBERS are pairs (m, n) of INTEGERS satisfying the condition of BROCARD'S PROBLEM, i.e., such that

$$n! + 1 = m^2, \tag{24}$$

where $n!$ is a FACTORIAL. Only three such numbers are known: (5,4), (11,5), (71,7). Erdős conjectured that these are the only three such pairs.

Either $5x^2 + 4 = y^2$ or $5x^2 - 4 = y^2$ has a solution in POSITIVE INTEGERS IFF, for some n, $(x, y) = (F_n, L_n)$, where F_n is a FIBONACCI NUMBER and L_n is a LUCAS NUMBER (Honsberger 1985, pp. 114–118).

The smallest and largest square numbers containing the digits 1 to 9 are

$$11,826^2 = 139,854,276, \tag{25}$$

$$30,384^2 = 923,187,456. \tag{26}$$

The smallest and largest square numbers containing the digits 0 to 9 are

$$32,043^2 = 1,026,753,849, \tag{27}$$

$$99,066^2 = 9,814,072,356 \tag{28}$$

(Madachy 1979, p. 159). The smallest and largest square numbers containing the digits 1 to 9 twice each are

$$335,180,136^2 = 112,345,723,568,978,496 \tag{29}$$

$$999,390,432^2 = 998,781,235,573,146,624, \tag{30}$$

and the smallest and largest containing 1 to 9 three times are

$$\begin{aligned} &10,546,200,195,312^2 \\ &\quad = 111,222,338,559,598,866,946,777,344 \quad (31) \\ &31,621,017,808,182^2 \\ &\quad = 999,888,767,225,363,175,346,145,124 \quad (32) \end{aligned}$$

(Madachy 1979, p. 159).

Madachy (1979, p. 165) also considers number which are equal to the sum of the squares of their two "halves" such as

$$1233 = 12^2 + 33^2 \tag{33}$$

$$8833 = 88^2 + 33^2 \tag{34}$$

$$10100 = 10^2 + 100^2 \tag{35}$$

$$5882353 = 588^2 + 2353^2, \tag{36}$$

in addition to a number of others.

Square Packing

Find the minimum size SQUARE capable of bounding n equal SQUARES arranged in any configuration. The only packings which have been proven optimal are 2, 3, 5, and SQUARE NUMBERS (4, 9, ...). If $n = a^2 - a$ for some a, it is CONJECTURED that the size of the minimum bounding square is a for small n. The smallest n for which the CONJECTURE is known to be violated is 1560. The size is known to scale as k^b, where

$$\tfrac{1}{2}(3-\sqrt{3}) < b < \tfrac{1}{2}.$$

n	Exact	Decimal

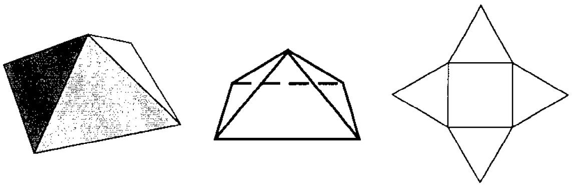
Square Pyramid



A square pyramid is a PYRAMID with a SQUARE base. If the top of the pyramid is cut off by a PLANE, a square PYRAMIDAL FRUSTUM is obtained. If the four TRIANGLES of the square pyramid are EQUILATERAL, the square pyramid is the "regular" POLYHEDRON known as JOHNSON SOLID J_1 and, for side length a, has height

$$h = \tfrac{1}{2}\sqrt{2}\,a. \tag{1}$$

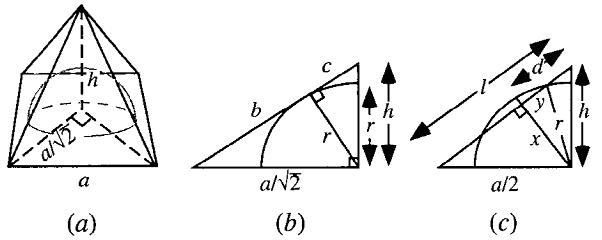
Using the equation for a general PYRAMID, the VOLUME of the "regular" is therefore

$$V = \tfrac{1}{3}hA_b = \tfrac{1}{6}\sqrt{2}\,a^3. \tag{2}$$

If the apex of the pyramid does not lie atop the center of the base, then the SLANT HEIGHT is given by

$$s = \sqrt{h^2 + \tfrac{1}{2}a^2}, \tag{3}$$

where h is the height and a is the length of a side of the base.



Consider a HEMISPHERE placed on the base of a square pyramid (having side lengths a and height h). Further, let the hemisphere be tangent to the four apex edges. Then what is the volume of the HEMISPHERE which is interior the pyramid (Cipra 1993)?

From Fig. (a), the CIRCUMRADIUS of the base is $a/\sqrt{2}$. Now find h in terms of r and a. Fig. (b) shows a CROSS-SECTION cut by the plane through the pyramid's apex, one of the base's vertices, and the base center. This figure gives

$$b = \sqrt{\tfrac12 a^2 - r^2} \tag{4}$$

$$c = \sqrt{h^2 - r^2}, \tag{5}$$

so the SLANT HEIGHT is

$$s = \sqrt{h^2 + \tfrac12 a^2} = b + c = \sqrt{\tfrac12 a^2 - r^2} + \sqrt{h^2 - r^2}. \tag{6}$$

Solving for h gives

$$h = \frac{ra}{\sqrt{a^2 - 2r^2}}. \tag{7}$$

We know, however, that the HEMISPHERE must be tangent to the sides, so $r = a/2$, and

$$h = \frac{\frac12 a}{\sqrt{a^2 - \frac12 a^2}} a = \frac{\frac12}{\sqrt{\frac12}} a = \tfrac12\sqrt{2}\, a. \tag{8}$$

Fig. (c) shows a CROSS-SECTION through the center, apex, and midpoints of opposite sides. The PYTHAGOREAN THEOREM once again gives

$$l = \sqrt{\tfrac14 a^2 + h^2} = \sqrt{\tfrac14 a^2 + \tfrac12 a^2} = \tfrac12\sqrt{3}\, a. \tag{9}$$

We now need to find x and y.

$$\sqrt{\tfrac14 a^2 - x^2} + d = l. \tag{10}$$

But we know l and h, and d is given by

$$d = \sqrt{h^2 - x^2}, \tag{11}$$

so

$$\sqrt{\tfrac14 a^2 - x^2} + \sqrt{\tfrac12 a^2 - x^2} = \tfrac12\sqrt{3}\, a. \tag{12}$$

Solving gives

$$x = \tfrac16\sqrt{6}\, a, \tag{13}$$

so

$$y = \sqrt{r^2 - x^2} = \sqrt{\tfrac14 - \tfrac16}\, a = \sqrt{\frac{3-2}{12}}\, a = \frac{a}{2\sqrt{3}}. \tag{14}$$

We can now find the AREA of the SPHERICAL CAP as

$$V_{\text{cap}} = \tfrac16 \pi H(3A^2 + H^2), \tag{15}$$

where

$$A \equiv y = \frac{a}{2\sqrt{3}} \tag{16}$$

$$H \equiv r - x = \tfrac12 a - \frac{a}{\sqrt{6}} = a\left(\frac12 - \frac{1}{\sqrt{6}}\right), \tag{17}$$

so

$$\begin{aligned} V_{\text{cap}} &= \tfrac16 \pi a^3 \left[3\left(\frac{1}{12}\right) + \left(\frac12 - \frac{1}{\sqrt{6}}\right)^2\right]\left(\frac12 - \frac{1}{\sqrt{6}}\right) \\ &= \tfrac16 \pi a^3 \left[\frac14 + \left(\frac14 + \frac16 - \frac{1}{\sqrt{6}}\right)\right]\left(\frac12 - \frac{1}{\sqrt{6}}\right) \\ &= \tfrac16 \pi a^3 \left(\frac23 - \frac{1}{\sqrt{6}}\right)\left(\frac12 - \frac{1}{\sqrt{6}}\right) \\ &= \tfrac16 \pi a^3 \left(\frac13 - \frac{1}{2\sqrt{6}} - \frac{2}{3\sqrt{6}} + \frac16\right) \\ &= \tfrac16 \pi a^3 \left(\frac12 - \frac{7}{6\sqrt{6}}\right). \end{aligned} \tag{18}$$

Therefore, the volume within the pyramid is

$$\begin{aligned} V_{\text{inside}} &= \tfrac23 \pi r^3 - 4V_{\text{cap}} = \tfrac23 \pi \tfrac18 a^3 - \tfrac23 \pi a^3 \left(\frac12 - \frac{7}{6\sqrt{6}}\right) \\ &= \tfrac23 \pi a^3 \left(\frac18 - \frac12 + \frac{7}{6\sqrt{6}}\right) = \tfrac23 \pi a^3 \left(\frac{7}{6\sqrt{6}} - \frac38\right) \\ &= \pi a^3 \left(\frac{7}{9\sqrt{6}} - \frac14\right). \end{aligned} \tag{19}$$

This problem appeared in the Japanese scholastic aptitude test (Cipra 1993).

Square Pyramidal Number

A FIGURATE NUMBER of the form

$$P_n = \tfrac{1}{6}n(n+1)(2n+1), \tag{1}$$

corresponding to a configuration of points which form a SQUARE PYRAMID, is called a square pyramidal number (or sometimes, simply a PYRAMIDAL NUMBER). The first few are 1, 5, 14, 30, 55, 91, 140, 204, ... (Sloane's A000330). They are sums of consecutive pairs of TETRAHEDRAL NUMBERS and satisfy

$$P_n = \tfrac{1}{3}(2n+1)T_n, \tag{2}$$

where T_n is the nth TRIANGULAR NUMBER.

The only numbers which are simultaneously SQUARE and pyramidal (the CANNONBALL PROBLEM) are $P_1 = 1$ and $P_{24} = 4900$, corresponding to $S_1 = 1$ and $S_{70} = 4900$ (Dickson 1952, p. 25; Ball and Coxeter 1987, p. 59; Ogilvy 1988), as conjectured by Lucas (1875, 1876) and proved by Watson (1918). The proof is far from elementary, and is equivalent to solving the DIOPHANTINE EQUATION

$$y^2 = \tfrac{1}{6}x(x+1)(2x+1) \tag{3}$$

(Guy 1994, p. 147). However, an elementary proof has also been given by a number of authors.

Numbers which are simultaneously TRIANGULAR and square pyramidal satisfy the DIOPHANTINE EQUATION

$$3(2y+1)^2 = 8x^3 + 12x^2 + 4x + 3. \tag{4}$$

The only solutions are $x = -1$, 0, 1, 5, 6, and 85 (Guy 1994, p. 147). Beukers (1988) has studied the problem of finding numbers which are simultaneously TETRAHEDRAL and square pyramidal via INTEGER points on an ELLIPTIC CURVE. He finds that the only solution is the trivial $Te_1 = P_1 = 1$.

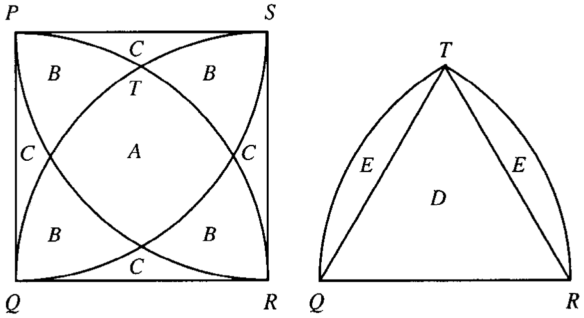
Square Quadrants



The areas of the regions illustrated above can be found from the equations

$$A + 4B + 4C = 1 \tag{1}$$

$$A + 3B + 2C = \tfrac{1}{4}\pi. \tag{2}$$

Since we want to solve for three variables, we need a third equation. This can be taken as

$$A + 2B + C = 2E + D, \tag{3}$$

where

$$D = \tfrac{1}{4}\sqrt{3} \tag{4}$$

$$D + E = \tfrac{1}{6}\pi, \tag{5}$$

leading to

$$A+2B+C = D+2E = 2(D+E)-D = \tfrac{1}{3}\pi - \tfrac{1}{4}\sqrt{3}. \tag{6}$$

Combining the equations (1), (2), and (6) gives the matrix equation

$$\begin{bmatrix} 1 & 4 & 4 \\ 1 & 3 & 2 \\ 1 & 2 & 1 \end{bmatrix} \begin{bmatrix} A \\ B \\ C \end{bmatrix} = \begin{bmatrix} 1 \\ \frac{1}{4}\pi \\ \frac{1}{3}\pi - \frac{1}{4}\sqrt{3} \end{bmatrix}, \tag{7}$$

which can be inverted to yield

$$A = 1 - \sqrt{3} - \tfrac{1}{3}\pi \tag{8}$$

$$B = -1 + \tfrac{1}{2}\sqrt{3} + \tfrac{1}{12}\pi \tag{9}$$

$$C = 1 - \tfrac{1}{4}\sqrt{3} + \tfrac{1}{6}\pi. \tag{10}$$

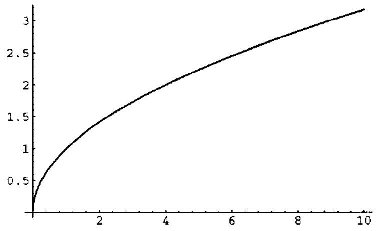
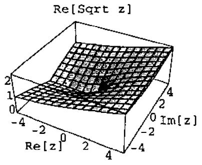
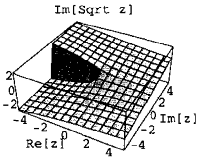
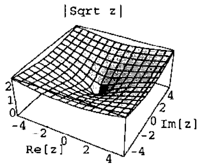
Square Root









A square root of x is a number r such that $r^2 = x$. This is written $r = x^{1/2}$ (x to the 1/2 POWER) or $r = \sqrt{x}$. The square root function $f(x) = \sqrt{x}$ is the INVERSE FUNCTION of $f(x) = x^2$. Square roots are also called RADICALS or SURDS. A general COMPLEX NUMBER z has *two* square roots. For example, for the real POSITIVE number $x = 9$, the two square roots are $\sqrt{9} = \pm 3$, since $3^2 = (-3)^2 = 9$. Similarly, for the real NEGATIVE number $x = -9$, the two square roots are $\sqrt{-9} = \pm 3i$, where i is the IMAGINARY NUMBER defined by $i^2 = -1$. In common usage, unless otherwise specified, "the" square root is generally taken to mean the POSITIVE square root.

The square root of 2 is the IRRATIONAL NUMBER $\sqrt{2} \approx 1.41421356$ (Sloane's A002193), which has the simple periodic CONTINUED FRACTION 1, 2, 2, 2, 2, 2, ... The square root of 3 is the IRRATIONAL NUMBER $\sqrt{3} \approx 1.73205081$ (Sloane's A002194), which has the simple periodic CONTINUED FRACTION 1, 1, 2, 1, 2, 1, 2, ... In general, the CONTINUED FRACTIONS of the square roots of all POSITIVE integers are periodic.

The square roots of a COMPLEX NUMBER are given by

$$\sqrt{x+iy} = \pm\sqrt{x^2+y^2}\left\{\cos\left[\frac{1}{2}\tan^{-1}\left(\frac{y}{x}\right)\right] + i\sin\left[\frac{1}{2}\tan^{-1}\left(\frac{y}{x}\right)\right]\right\}. \quad (1)$$

As can be seen in the above figure, the IMAGINARY PART of the complex square root function has a BRANCH CUT along the NEGATIVE real axis.

A NESTED RADICAL of the form $\sqrt{a \pm b\sqrt{c}}$ can sometimes be simplified into a simple square root by equating

$$\sqrt{a \pm b\sqrt{c}} = \sqrt{d} \pm \sqrt{e}. \quad (2)$$

Squaring gives

$$a \pm b\sqrt{c} = d + e \pm 2\sqrt{de}, \quad (3)$$

so

$$a = d + e \quad (4)$$

$$b^2 c = 4de. \quad (5)$$

Solving for d and e gives

$$d, e = \frac{a \pm \sqrt{a^2 - b^2 c}}{2}. \quad (6)$$

A sequence of approximations a/b to $\sqrt{n}$ can be derived by factoring

$$a^2 - nb^2 = \pm 1 \quad (7)$$

(where -1 is possible only if -1 is a QUADRATIC RESIDUE of n). Then

$$(a + b\sqrt{n})(a - b\sqrt{n}) = \pm 1 \quad (8)$$

$$(a + b\sqrt{n})^k (a - b\sqrt{n})^k = (\pm 1)^k = \pm 1, \quad (9)$$

and

$$(1 + \sqrt{n})^1 = 1 + \sqrt{n} \quad (10)$$

$$(1 + \sqrt{n})^2 = (1 + n) + 2\sqrt{n} \quad (11)$$

$$(1 + \sqrt{n})(a + b\sqrt{n}) = (a + bn) + \sqrt{n}(a + b). \quad (12)$$

Therefore, a and b are given by the RECURRENCE RELATIONS

$$a_i = a_{i-1} + b_{i-1} n \quad (13)$$

$$b_i = a_{i-1} + b_{i-1} \quad (14)$$

with $a_1 = b_1 = 1$. The error obtained using this method is

$$\left|\frac{a}{b} - \sqrt{n}\right| = \frac{1}{b(a + b\sqrt{n})} < \frac{1}{2b^2}. \quad (15)$$

The first few approximants to $\sqrt{n}$ are therefore given by

$$1, \tfrac{1}{2}(1+n), \frac{1+3n}{3+n}, \frac{1+6n+n^2}{4(n+1)}, \frac{1+10n+5n^2}{5+10n+n^2}, \ldots. \quad (16)$$

This ALGORITHM is sometimes known as the BHASKARA-BROUCKNER ALGORITHM. For the case $n = 2$, this gives the convergents to $\sqrt{2}$ as 1, 3/2, 7/5, 17/12, 41/29, 99/70, ...

Another general technique for deriving this sequence, known as NEWTON'S ITERATION, is obtained by letting $x = \sqrt{n}$. Then $x = n/x$, so the SEQUENCE

$$x_k = \frac{1}{2}\left(x_{k-1} + \frac{n}{x_{k-1}}\right) \quad (17)$$

converges quadratically to the root. The first few approximants to $\sqrt{n}$ are therefore given by

$$1, \tfrac{1}{2}(1+n), \frac{1+6n+n^2}{4(n+1)}, \frac{1+26n+70n^2+28n^3+n^4}{8(1+n)(1+6n+n^2)}, \ldots. \quad (18)$$

For $\sqrt{2}$, this gives the convergents 1, 3/2, 17/12, 577/408, 665857/470832, ...

Square Root Inequality

$$2\sqrt{n+1}-2\sqrt{n}<\frac{1}{\sqrt{n}}<2\sqrt{n}-2\sqrt{n-1}\,.$$

Square Root Method

The square root method is an algorithm which solves the MATRIX EQUATION

$$\mathsf{A}\mathbf{u}=\mathbf{g} \tag{1}$$

for $\mathbf{u}$, with A a $p\times p$ SYMMETRIC MATRIX and $\mathbf{g}$ a given VECTOR. Convert A to a TRIANGULAR MATRIX such that

$$\mathsf{T}^{\mathrm{T}}\mathsf{T}=\mathsf{A}, \tag{2}$$

where T^{T} is the MATRIX TRANSPOSE. Then

$$\mathsf{T}^{\mathrm{T}}\mathbf{k}=\mathbf{g} \tag{3}$$

$$\mathsf{T}\mathbf{u}=\mathbf{k}, \tag{4}$$

so

$$\mathsf{T}=\begin{bmatrix} s_{11} & s_{12} & \cdots & \cdots \\ 0 & s_{22} & \cdots & \cdots \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & s_{pp} \end{bmatrix}, \tag{5}$$

giving the equations

$$\begin{aligned} {s_{11}}^2 &= a_{11} \\ s_{11}s_{12} &= a_{12} \\ {s_{12}}^2+{s_{22}}^2 &= a_{22} \\ {s_{1j}}^2+{s_{2j}}^2+\ldots+{s_{jj}}^2 &= a_{jj} \\ s_{1j}+s_{2j}s_{2k}+\ldots+s_{jj}s_{jk} &= a_{jk}. \end{aligned} \tag{6}$$

These give

$$\begin{aligned} s_{11} &= \sqrt{a_{11}} \\ s_{12} &= \frac{a_{12}}{s_{11}} \\ s_{22} &= \sqrt{a_{22}-{s_{12}}^2} \\ s_{jj} &= \sqrt{a_{jj}-{s_{ij}}^2-{s_{2j}}^2-\ldots-{s_{j-1,j}}^2} \\ s_{jk} &= \frac{a_{jk}-s_{1j}s_{1k}-s_{2j}s_{2k}-\ldots-s_{j-1,j}s_{j-1,k}}{s_{jj}}, \end{aligned} \tag{7}$$

giving T from A. Now solve for $\mathbf{k}$ in terms of the s_{ij}s and $\mathbf{g}$,

$$\begin{aligned} s_{11}k_1 &= g_1 \\ s_{12}k_1+s_{22}k_2 &= g_2 \\ s_{1j}k_1+s_{2j}k_2+\ldots+s_{jj}k_j &= g_j, \end{aligned} \tag{8}$$

which gives

$$\begin{aligned} k_1 &= \frac{g_1}{s_{11}} \\ k_2 &= \frac{g_2-s_{12}k_1}{s_{22}} \\ k_j &= \frac{g_j-s_{1j}k_1-s_{2j}k_2-\ldots-s_{j-1,j}k_{j-1}}{s_{jj}}. \end{aligned} \tag{9}$$

Finally, find $\mathbf{u}$ from the s_{ij}s and $\mathbf{k}$,

$$\begin{aligned} s_{11}u_1+s_{12}u_2\ldots+s_{1p}u_p &= k_1 \\ s_{22}u_2+\ldots+s_{2p}u_p &= k_2 \\ s_{pp}u_p &= k_p, \end{aligned} \tag{10}$$

giving the desired solution,

$$\begin{aligned} u_p &= \frac{k_p}{s_{pp}} \\ u_{p-1} &= \frac{k_{p-1}-s_{p-1,p}u_p}{s_{p-1,p-1}} \\ u_j &= \frac{k_j-s_{j,j+1}u_{j+1}-s_{j,j+2}u_{j+2}-\ldots-s_{jp}u_p}{s_{jj}}. \end{aligned} \tag{11}$$

Square Triangular Number

A number which is simultaneously SQUARE and TRIANGULAR. The first few are 1, 36, 1225, 41616, 1413721, 48024900, ... (Sloane's A001110), corresponding to $T_1=S_1$, $T_8=S_6$, $T_{49}=S_{35}$, $T_{288}=S_{204}$, $T_{1681}=S_{1189}$, ... (Pietenpol 1962), but there are an infinite number, as first shown by Euler in 1730 (Dickson 1952).

The general FORMULA for a square triangular number ST_n is b^2c^2, where b/c is the nth convergent to the CONTINUED FRACTION of $\sqrt{2}$ (Ball and Coxeter 1987, p. 59; Conway and Guy 1996). The first few are

$$\frac{1}{1},\frac{3}{2},\frac{7}{5},\frac{17}{12},\frac{41}{29},\frac{99}{70},\frac{239}{169},\ldots. \tag{1}$$

The NUMERATORS and DENOMINATORS give solutions to the PELL EQUATION

$$x^2-2y^2=\pm1, \tag{2}$$

but can also be obtained by doubling the previous FRACTION and adding to the FRACTION before that. The connection with the PELL EQUATION can be seen by letting N denote the Nth TRIANGULAR NUMBER and M the Mth SQUARE NUMBER, then

$$\tfrac{1}{2}N(N+1) = M^2. \tag{3}$$

Defining

$$x \equiv 2N+1 \tag{4}$$
$$y \equiv 2M \tag{5}$$

then gives the equation

$$x^2 - 2y^2 = 1 \tag{6}$$

(Conway and Guy 1996). Numbers which are simultaneously TRIANGULAR and SQUARE PYRAMIDAL also satisfy the DIOPHANTINE EQUATION

$$3(2y+1)^2 = 8x^3 + 12x^2 + 4x + 3. \tag{7}$$

The only solutions are $x = -1$, 0, 1, 5, 6, and 85 (Guy 1994, p. 147).

A general FORMULA for square triangular numbers is

$$ST_n = \left[\frac{(1+\sqrt{2})^{2n} - (1-\sqrt{2})^{2n}}{4\sqrt{2}}\right]^2 \tag{8}$$
$$= \tfrac{1}{32}[(17+12\sqrt{2})^n + (17-12\sqrt{2})^n - 2]. \tag{9}$$

The square triangular numbers also satisfy the RECURRENCE RELATION

$$ST_n = 34ST_{n-1} - ST_{n-2} + 2 \tag{10}$$
$$u_{n+2} = 6u_{n+1} - u_n, \tag{11}$$

with $u_0 = 0$, $u_1 = 1$, where $ST_n \equiv {u_n}^2$. A curious product formula for ST_n is given by

$$ST_n = 2^{2n-5}\prod_{k=1}^{2n}\left[3+\cos\left(\frac{k\pi}{n}\right)\right]. \tag{12}$$

An amazing GENERATING FUNCTION is

$$f(x) = \frac{1+x}{(1-x)(1-34x+x^2)} = 1 + 36x + 1225x^2 + \ldots \tag{13}$$

(Sloane and Plouffe 1995).

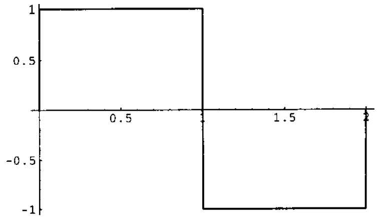
Square Wave



The square wave is a periodic waveform consisting of instantaneous transitions between two levels which can be denoted ±1. The square wave is sometimes also called the RADEMACHER FUNCTION. Let the square wave have period $2L$. The square wave function is ODD, so the FOURIER SERIES has $a_0 = a_n = 0$ and

$$b_n = \frac{2}{L}\int_0^L \sin\left(\frac{n\pi x}{L}\right)\,dx$$
$$= \frac{4}{n\pi}\sin^2(\tfrac{1}{2}n\pi) = \frac{4}{n\pi}\begin{cases} 0 & n \text{ even} \\ 1 & n \text{ odd.}\end{cases}$$

The FOURIER SERIES for the square wave is therefore

$$f(x) = \frac{4}{\pi}\sum_{n=1,3,5,\ldots}^{\infty}\frac{1}{n}\sin\left(\frac{n\pi x}{L}\right).$$

Squared

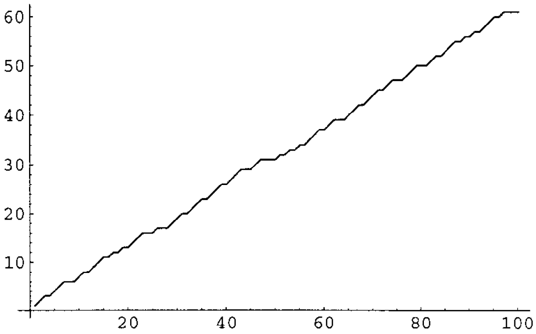
A number to the POWER 2 is said to be squared, so that x^2 is called "x squared."

see also CUBED, SQUARE ROOT

Squared Square

see PERFECT SQUARE DISSECTION

Squarefree



A number is said to be squarefree (or sometimes QUADRATFREI; Shanks 1993) if its PRIME decomposition contains no repeated factors. All PRIMES are therefore trivially squarefree. The squarefree numbers are 1, 2, 3, 5, 6, 7, 10, 11, 13, 14, 15, ... (Sloane's A005117). The SQUAREFUL numbers (i.e., those that contain at least one square) are 4, 8, 9, 12, 16, 18, 20, 24, 25, ... (Sloane's A013929).

The asymptotic number $Q(n)$ of squarefree numbers $\leq n$ is given by

$$Q(n) = \frac{6n}{\pi^2} + \mathcal{O}(\sqrt{n}) \qquad (1)$$

(Hardy and Wright 1979, pp. 269–270). $Q(n)$ for $n = 10, 100, 1000, \ldots$ are 7, 61, 608, 6083, 60794, 607926, ..., while the asymptotic density is $1/\zeta(2) = 6/\pi^2 \approx 0.607927$, where $\zeta(n)$ is the RIEMANN ZETA FUNCTION.

The MÖBIUS FUNCTION is given by

$$\mu(n) \equiv \begin{cases} 0 & \text{if } n \text{ has one or more repeated prime factors} \\ 1 & \text{if } n = 1 \\ (-1)^k & \text{if } n \text{ is product of } k \text{ distinct primes,} \end{cases} \qquad (2)$$

so $\mu(n) \neq 0$ indicates that n is squarefree. The asymptotic formula for $Q(x)$ is equivalent to the formula

$$\sum_{n=1}^{x} |\mu(n)| = \frac{6x}{\pi^2} + \mathcal{O}(\sqrt{x}) \qquad (3)$$

(Hardy and Wright 1979, p. 270)

There is no known polynomial-time algorithm for recognizing squarefree INTEGERS or for computing the squarefree part of an INTEGER. In fact, this problem may be no easier than the general problem of integer factorization (obviously, if an integer n can be factored completely, n is squarefree IFF it contains no duplicated factors). This problem is an important unsolved problem in NUMBER THEORY because computing the RING of integers of an algebraic number field is reducible to computing the squarefree part of an INTEGER (Lenstra 1992, Pohst and Zassenhaus 1997). The *Mathematica®* (Wolfram Research, Champaign, IL) function `NumberTheory'NumberTheoryFunctions'` `SquareFreeQ[n]` determines whether a number is squarefree.

The largest known SQUAREFUL FIBONACCI NUMBER is F_{336}, and no SQUAREFUL FIBONACCI NUMBERS F_p are known with p PRIME. All numbers less than 2.5×10^{15} in SYLVESTER'S SEQUENCE are squarefree, and no SQUAREFUL numbers in this sequence are known (Vardi 1991). Every CARMICHAEL NUMBER is squarefree. The BINOMIAL COEFFICIENTS $\binom{2n-1}{n}$ are squarefree only for $n = 2, 3, 4, 6, 9, 10, 12, 36, \ldots$, with no others less than $n = 1500$. The CENTRAL BINOMIAL COEFFICIENTS are SQUAREFREE only for $n = 1, 2, 3, 4, 5, 7, 8, 11, 17, 19, 23, 71, \ldots$ (Sloane's A046098), with no others less than 1500.

Squareful

A number is squareful, also called NONSQUAREFREE, if it contains at least one SQUARE in its prime factorization. Such a number is also called SQUAREFUL. The first few are 4, 8, 9, 12, 16, 18, 20, 24, 25, ... (Sloane's A013929). The greatest multiple prime factors for the squareful integers are 2, 2, 3, 2, 2, 3, 2, 2, 5, 3, 2, 2, 3, ... (Sloane's A046028). The least multiple prime factors for squareful integers are 2, 2, 3, 2, 2, 3, 2, 2, 5, 3, 2, 2, 2, ... (Sloane's A046027).

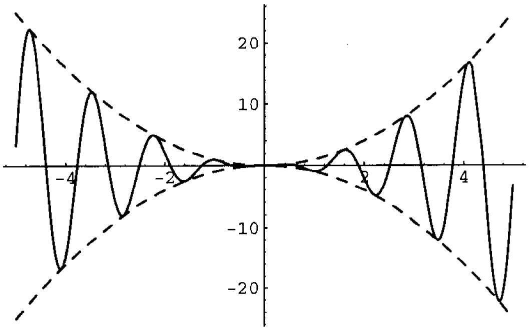
Squaring

Squaring is the GEOMETRIC CONSTRUCTION, using only COMPASS and STRAIGHTEDGE, of a SQUARE which has the same area as a given geometric figure. Squaring is also called QUADRATURE. An object which can be constructed by squaring is called SQUARABLE.

see also CIRCLE SQUARING, COMPASS, CONSTRUCTIBLE NUMBER, GEOMETRIC CONSTRUCTION, RECTANGLE SQUARING, STRAIGHTEDGE, TRIANGLE SQUARING

Squeezing Theorem



Let there be two functions $f_-(x)$ and $f_+(x)$ such that $f(x)$ is "squeezed" between the two,

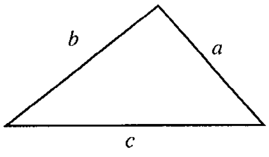
$$f_-(x) \leq f(x) \leq f_+(x).$$

If

$$r = \lim_{x \to a} f_-(x) = \lim_{x \to a} f_+(x),$$

then $\lim_{x \to a} f(x) = r$. In the above diagram the functions $f_-(x) = -x^2$ and $f_+(x) = x^2$ "squeeze" $x^2 \sin(cx)$ at 0, so $\lim_{x \to 0} x^2 \sin(cx) = 0$. The squeezing theorem is also called the SANDWICH THEOREM.

SSS Theorem



Specifying three sides uniquely determines a TRIANGLE whose AREA is given by HERON'S FORMULA,

$$A = \sqrt{s(s-a)(s-b)(s-c)}, \tag{1}$$

where

$$s \equiv \tfrac{1}{2}(a+b+c) \tag{2}$$

is the SEMIPERIMETER of the TRIANGLE. Let R be the CIRCUMRADIUS, then

$$A = \frac{abc}{4R}. \tag{3}$$

Using the LAW OF COSINES

$$a^2 = b^2 + c^2 - 2bc \cos A \tag{4}$$

$$b^2 = a^2 + c^2 - 2ac \cos B \tag{5}$$

$$c^2 = a^2 + b^2 - 2ab \cos C \tag{6}$$

gives the three ANGLES as

$$A = \cos^{-1}\left(\frac{b^2 + c^2 - a^2}{2bc}\right) \tag{7}$$

$$B = \cos^{-1}\left(\frac{b^2 + c^2 - b^2}{2ac}\right) \tag{8}$$

$$C = \cos^{-1}\left(\frac{a^2 + b^2 - c^2}{2ab}\right). \tag{9}$$

see also AAA THEOREM, AAS THEOREM, ASA THEOREM, ASS THEOREM, HERON'S FORMULA, SAS THEOREM, SEMIPERIMETER, TRIANGLE

Stability

The robustness of a given outcome to small changes in initial conditions or small random fluctuations. CHAOS is an example of a process which is not stable.

see also STABILITY MATRIX

Stability Matrix

Given a system of two ordinary differential equations

$$\dot{x} = f(x, y) \tag{1}$$

$$\dot{y} = g(x, y), \tag{2}$$

let x_0 and y_0 denote FIXED POINTS with $\dot{x} = \dot{y} = 0$, so

$$f(x_0, y_0) = 0 \tag{3}$$

$$g(x_0, y_0) = 0. \tag{4}$$

Then expand about (x_0, y_0) so

$$\begin{aligned}\delta\dot{x} &= f_x(x_0, y_0)\delta x + f_y(x_0, y_0)\delta y \\ &\quad + f_{xy}(x_0, y_0)\delta x \delta y + \ldots \end{aligned} \tag{5}$$

$$\begin{aligned}\delta\dot{y} &= g_x(x_0, y_0)\delta x + g_y(x_0, y_0)\delta y \\ &\quad + g_{xy}(x_0, y_0)\delta x \delta y + \ldots. \end{aligned} \tag{6}$$

To first-order, this gives

$$\frac{d}{dt}\begin{bmatrix} \delta x \\ \delta y \end{bmatrix} = \begin{bmatrix} f_x(x_0, y_0) & f_y(x_0, y_0) \\ g_x(x_0, y_0) & g_y(x_0, y_0) \end{bmatrix} \begin{bmatrix} \delta x \\ \delta y \end{bmatrix}, \tag{7}$$

where the 2×2 MATRIX, or its generalization to higher dimension, is called the stability matrix. Analysis of the EIGENVALUES (and EIGENVECTORS) of the stability matrix characterizes the type of FIXED POINT.

Stable Type

A Polynomial equation whose Roots all have Negative Real Parts. For a Real Quadratic Equation

$$z^2 + Bz + C = 0,$$

the stability conditions are $B, C > 0$. For a Real Cubic Equation

$$z^3 + Az^2 + Bz + C = 0,$$

the stability conditions are $A, B, C > 0$ and $AB > C$.

Stack

A Data Structure which is a special kind of List in which elements may be added to or removed from the top only. These actions are called a Push or a Pop, respectively. Actions may be taken by popping one or more values, operating on them, and then pushing the result back onto the stack.

Stacks are used as the basis for computer languages such as FORTH, PostScript® (Adobe Systems), and the RPN language used in Hewlett-Packard® programmable calculators.

see also List, Pop, Push, Queue

Stäckel Determinant

A DETERMINANT used to determine in which coordinate systems the HELMHOLTZ DIFFERENTIAL EQUATION is separable (Morse and Feshbach 1953). A determinant

$$S = |\Phi_{mn}| = \begin{vmatrix} \Phi_{11} & \Phi_{12} & \Phi_{13} \\ \Phi_{21} & \Phi_{22} & \Phi_{23} \\ \Phi_{31} & \Phi_{32} & \Phi_{33} \end{vmatrix} \tag{1}$$

in which Φ_{ni} are functions of u_i alone is called a Stäckel determinant. A coordinate system is separable if it obeys the ROBERTSON CONDITION, namely that the SCALE FACTORS h_i in the LAPLACIAN

$$\nabla^2 = \sum_{i=1}^{3} \frac{1}{h_1h_2h_3}\frac{\partial}{\partial u_i}\left(\frac{h_1h_2h_3}{{h_i}^2}\frac{\partial}{\partial u_i}\right) \tag{2}$$

can be rewritten in terms of functions $f_i(u_i)$ defined by

$$\begin{aligned} \frac{1}{h_1h_2h_3}\frac{\partial}{\partial u_i}\left(\frac{h_1h_2h_3}{{h_i}^2}\frac{\partial}{\partial u_i}\right) &= \frac{g(u_{i+1},u_{i+2})}{h_1h_2h_3}\frac{\partial}{\partial u_i}\left[f_i(u_i)\frac{\partial}{\partial u_i}\right] \\ &= \frac{1}{{h_i}^2 f_i}\frac{\partial}{\partial u_i}\left(f_i\frac{\partial}{\partial u_i}\right) \end{aligned} \tag{3}$$

such that S can be written

$$S = \frac{h_1h_2h_3}{f_1(u_1)f_2(u_2)f_3(u_3)}. \tag{4}$$

When this is true, the separated equations are of the form

$$\frac{1}{f_n}\frac{\partial}{\partial u_n}\left(f_n\frac{\partial X_n}{\partial u_n}\right) + ({k_1}^2\Phi_{n1} + {k_2}^2\Phi_{n2} + {k_3}^2\Phi_{n3})X_n = 0 \tag{5}$$

The Φ_{ij}s obey the minor equations

$$M_1 = \Phi_{22}\Phi_{33} - \Phi_{23}\Phi_{32} = \frac{S}{h_1^2} \tag{6}$$

$$M_2 = \Phi_{13}\Phi_{31} - \Phi_{12}\Phi_{33} = \frac{S}{h_2^2} \tag{7}$$

$$M_3 = \Phi_{12}\Phi_{23} - \Phi_{13}\Phi_{22} = \frac{S}{h_3^2}, \tag{8}$$

which are equivalent to

$$M_1\Phi_{11} + M_2\Phi_{21} + M_3\Phi_{31} = S \tag{9}$$

$$M_1\Phi_{12} + M_2\Phi_{22} + M_3\Phi_{32} = 0 \tag{10}$$

$$M_1\Phi_{13} + M_2\Phi_{23} + M_3\Phi_{33} = 0. \tag{11}$$

This gives a total of four equations in nine unknowns. Morse and Feshbach (1953, pp. 655–666) give not only the Stäckel determinants for common coordinate systems, but also the elements of the determinant (although it is not clear how these are derived).

Stamp Folding

The number of ways of folding a strip of stamps has several possible variants. Considering only positions of the hinges for unlabeled stamps without regard to orientation of the stamps, the number of foldings is denoted $U(n)$. If the stamps are labelled and orientation is taken into account, the number of foldings is denoted $N(n)$. Finally, the number of symmetric foldings is denoted $S(n)$. The following table summarizes these values for the first n.

n	$S(n)$	$U(n)$	$N(n)$
1	1	1	1
2	1	1	1
3	2	2	6
4	4	5	16
5	6	14	50
6	8	39	144
7	18	120	462
8	20	358	1392
9	56	1176	4536
10		3572

Standard Deviation

The standard deviation is defined as the SQUARE ROOT of the VARIANCE,

$$\sigma = \sqrt{\langle x^2\rangle - \langle x\rangle^2} = \sqrt{\mu_2' - \mu^2}, \tag{1}$$

where $\mu = \langle x\rangle$ is the MEAN and $\mu_2' = \langle x^2\rangle$ is the second MOMENT about 0. The variance σ^2 is equal to the second MOMENT about the MEAN,

$$\sigma^2 = \mu_2. \tag{2}$$

The square root of the SAMPLE VARIANCE is the "sample" standard deviation,

$$s_N = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(x_i - \bar{x})^2}. \tag{3}$$

It is a Biased Estimator of the population standard deviation. As unbiased Estimator is given by

$$s_{N-1} = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}(x_i - \bar{x})^2}. \qquad (4)$$

Physical scientists often use the term Root-Mean-Square as a synonym for standard deviation when they refer to the Square Root of the mean squared deviation of a signal from a given baseline or fit.

see also Mean, Moment, Root-Mean-Square, Sample Variance, Standard Error, Variance

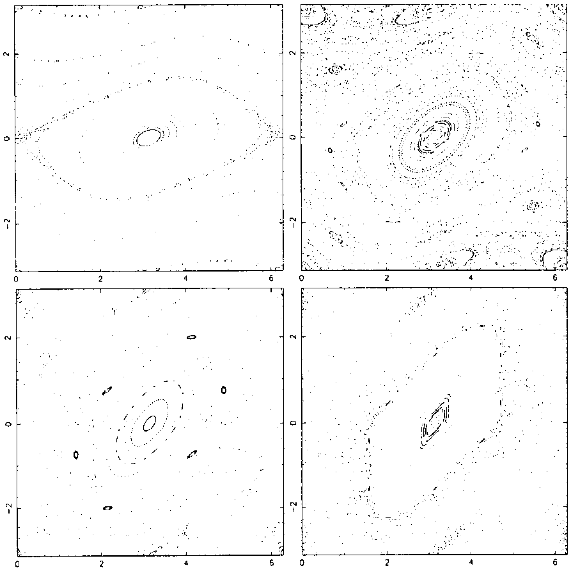
Standard Error

The square root of the Estimated Variance of a quantity. The standard error is also sometimes used to mean

$$\mathrm{var}(\bar{x}) = \sum_{i=1}^{n}\left(\frac{1}{n}\right)^2 {\sigma_i}^2 = \sum_{i=1}^{n}\left(\frac{1}{n}\right)^2 \sigma^2 = \frac{\sigma^2}{n}.$$

see also Standard Deviation

Standard Map



A 2-D Map, also called the Taylor-Greene-Chirikov Map in some of the older literature.

$$I_{n+1} = I_n + K\sin\theta_n \qquad (1)$$
$$\theta_{n+1} = \theta_n + I_{n+1} = I_n + \theta_n + K\sin\theta_n, \qquad (2)$$

where I and θ are computed mod 2π and K is a Positive constant. An analytic estimate of the width of the Chaotic zone (Chirikov 1979) finds

$$\delta I = Be^{-AK^{-1/2}}. \qquad (3)$$

Numerical experiments give $A \approx 5.26$ and $B \approx 240$. The value of K at which global Chaos occurs has been bounded by various authors. Greene's Method is the most accurate method so far devised.

Author	Bound	Fraction	Decimal
Hermann	$>$	$\frac{1}{34}$	0.029411764
Italians	$>$	–	0.65
Greene	$\approx$	–	0.971635406
MacKay and Pearson	$<$	$\frac{63}{64}$	0.984375000
Mather	$<$	$\frac{4}{3}$	1.333333333

Fixed Points are found by requiring that

$$I_{n+1} = I_n \qquad (4)$$
$$\theta_{n+1} = \theta_n. \qquad (5)$$

The first gives $K\sin\theta_n = 0$, so $\sin\theta_n = 0$ and

$$\theta_n = 0, \pi. \qquad (6)$$

The second requirement gives

$$I_n + K\sin\theta_n = I_n = 0. \qquad (7)$$

The Fixed Points are therefore $(I,\theta) = (0,0)$ and $(0,\pi)$. In order to perform a Linear Stability analysis, take differentials of the variables

$$dI_{n+1} = dI_n + K\cos\theta_n\, d\theta_n \qquad (8)$$
$$d\theta_{n+1} = dI_n + (1 + K\cos\theta_n)\, d\theta_n. \qquad (9)$$

In Matrix form,

$$\begin{bmatrix}\delta I_{n+1}\\ \delta\theta_{n+1}\end{bmatrix} = \begin{bmatrix}1 & K\cos\theta_n\\ 1 & 1+K\cos\theta_n\end{bmatrix}\begin{bmatrix}\delta I_n\\ \delta\theta_n\end{bmatrix}. \qquad (10)$$

The Eigenvalues are found by solving the Characteristic Equation

$$\begin{vmatrix}1-\lambda & K\cos\theta_n\\ 1 & 1+K\cos\theta_n-\lambda\end{vmatrix} = 0, \qquad (11)$$

so

$$\lambda^2 - \lambda(K\cos\theta_n + 2) + 1 = 0 \qquad (12)$$
$$\lambda_\pm = \tfrac{1}{2}[K\cos\theta_n + 2 \pm \sqrt{(K\cos\theta_n + 2)^2 - 4}\,]. \qquad (13)$$

For the Fixed Point $(0,\pi)$,

$$\lambda_\pm^{(0,\pi)} = \tfrac{1}{2}[2 - K \pm \sqrt{(2-K)^2 - 4}\,]$$
$$= \tfrac{1}{2}(2 - K \pm \sqrt{K^2 - 4K}\,). \qquad (14)$$

The Fixed Point will be stable if $|\Re(\lambda^{(0,\pi)})| < 2$. Here, that means

$$\tfrac{1}{2}|2-K| < 1 \qquad (15)$$
$$|2-K| < 2 \qquad (16)$$
$$-2 < 2-K < 2 \qquad (17)$$
$$-4 < -K < 0 \qquad (18)$$

so $K \in [0,4)$. For the FIXED POINT (0, 0), the EIGENVALUES are

$$\begin{aligned}\lambda_{\pm}^{(0,0)} &= \tfrac{1}{2}[2+K\pm\sqrt{(K+2)^2-4}\,]\\ &= \tfrac{1}{2}(2+K\pm\sqrt{K^2+4K}\,). \qquad (19)\end{aligned}$$

If the map is unstable for the larger EIGENVALUE, it is unstable. Therefore, examine $\lambda_{+}^{(0,0)}$. We have

$$\frac{1}{2}\left|2+K+\sqrt{K^2+4K}\right| < 1, \qquad (20)$$

so

$$-2 < 2+K+\sqrt{K^2+4K} < 2 \qquad (21)$$

$$-4-K < \sqrt{K^2+4K} < -K. \qquad (22)$$

But $K > 0$, so the second part of the inequality cannot be true. Therefore, the map is unstable at the FIXED POINT (0, 0).

Standard Normal Distribution

A NORMAL DISTRIBUTION with zero MEAN ($\mu = 0$) and unity STANDARD DEVIATION ($\sigma^2 = 1$).

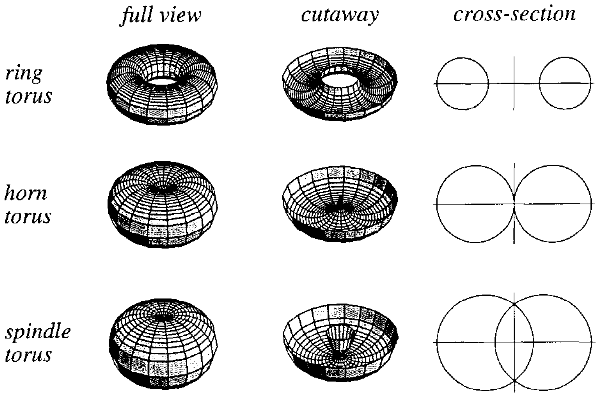
see also NORMAL DISTRIBUTION

Standard Space

A SPACE which is ISOMORPHIC to a BOREL SUBSET B of a POLISH SPACE equipped with its SIGMA ALGEBRA of BOREL SETS.

see also BOREL SET, POLISH SPACE, SIGMA ALGEBRA

Standard Tori



One of the three classes of TORI illustrated above and given by the parametric equations

$$x = (c + a\cos v)\cos u \qquad (1)$$

$$y = (c + a\cos v)\sin u \qquad (2)$$

$$z = a\sin v. \qquad (3)$$

The three different classes of standard tori arise from the three possible relative sizes of a and c. $c > a$ corresponds to the RING TORUS shown above, $c = a$ corresponds to a HORN TORUS which touches itself at the point (0, 0, 0), and $c < a$ corresponds to a self-intersecting SPINDLE TORUS (Pinkall 1986). If no specification is made, "torus" is taken to mean RING TORUS.

The standard tori and their inversions are CYCLIDES.

see also APPLE, CYCLIDE, HORN TORUS, LEMON, RING TORUS, SPINDLE TORUS, TORUS

Standardized Moment

Defined for samples x_i, $i = 1, \ldots, N$ by

$$\alpha_r \equiv \frac{1}{N}\sum_{i=1}^{N} {z_i}^r = \frac{\mu_r}{\sigma^r}, \qquad (1)$$

where

$$z_i \equiv \frac{x_i - \bar{x}}{s_x}. \qquad (2)$$

The first few are

$$\alpha_1 = 0 \qquad (3)$$

$$\alpha_2 = 1 \qquad (4)$$

$$\alpha_3 = \frac{\mu_3}{s^3} \qquad (5)$$

$$\alpha_4 = \frac{\mu_4}{s^4}. \qquad (6)$$

Star

In formal geometry, a star is a set of $2n$ VECTORS $\pm\mathbf{a}_1$, ..., $\pm\mathbf{a}_n$ which form a fixed center in EUCLIDEAN 3-SPACE. In common usage, a star is a STAR POLYGON (i.e., regular convex polygon) such as the PENTAGRAM or HEXAGRAM

see also CROSS, EUTACTIC STAR, STAR OF GOLIATH, STAR POLYGON

Star of David

see HEXAGRAM

Star Figure

A STAR POLYGON-like figure $\left\{\frac{p}{q}\right\}$ for which p and q are not RELATIVELY PRIME.

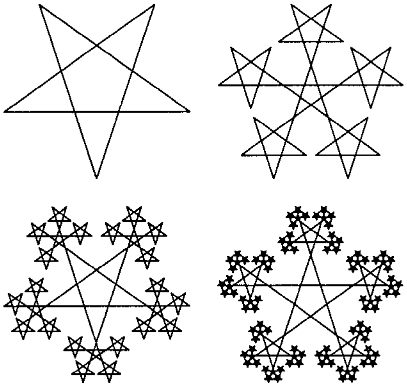
see also STAR POLYGON

Star (Fixed Point)

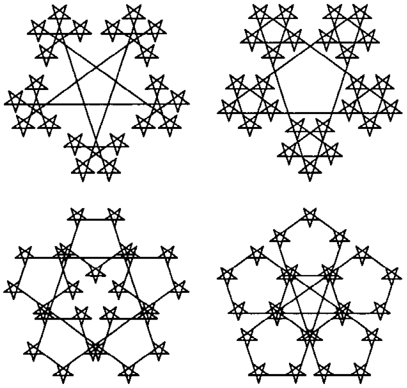
A FIXED POINT which has one zero EIGENVECTOR.

see STABLE STAR, UNSTABLE STAR

Star Fractal



A FRACTAL composed of repeated copies of a PENTAGRAM or other polygon.



The above figure shows a generalization to different offsets from the center.

References

Savio, D. Y. and Suryanaroyan, E. R. "Chebyshev Polynomials and Regular Polygons." *Amer. Math. Monthly* **100**, 657–661, 1993.

Star Number

The number of cells in a generalized Chinese checkers board (or "centered" HEXAGRAM).

$$S_n = 6n(n+1)+1 = S_{n-1}+12(n-1). \quad (1)$$

The first few are 1, 13, 37, 73, 121, ... (Sloane's A003154). Every star number has DIGITAL ROOT 1 or 4, and the final digits must be one of: 01, 21, 41, 61, 81, 13, 33, 53, 73, 93, or 37.

The first TRIANGULAR star numbers are 1, 253, 49141, 9533161, ... (Sloane's A006060), and can be computed using

$$\begin{aligned} TS_n &= \frac{3[(7+4\sqrt{3})^{2n-1}+(7-4\sqrt{3})^{2n-1}]-10}{32} \\ &= 194TS_{n-1}+60-TS_{n-2}. \end{aligned} \quad (2)$$

The first few SQUARE star numbers are 1, 121, 11881, 1164241, 114083761, ... (Sloane's A006061). SQUARE star numbers are obtained by solving the DIOPHANTINE EQUATION

$$2x^2+1=3y^2 \quad (3)$$

and can be computed using

$$SS_n = \frac{[(5+2\sqrt{6})^n(\sqrt{6}-2)-(5-2\sqrt{6})^n(\sqrt{6}+2)]^2}{4}. \tag{4}$$

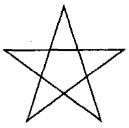
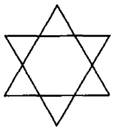
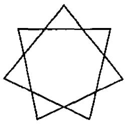
Star Polygon



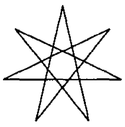
$\{\frac{5}{2}\}$



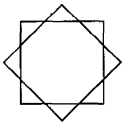
$\{\frac{6}{2}\}$



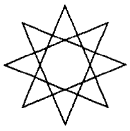
$\{\frac{7}{2}\}$



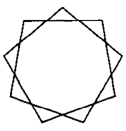
$\{\frac{7}{3}\}$



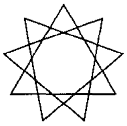
$\{\frac{8}{2}\}$



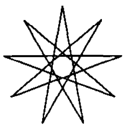
$\{\frac{8}{3}\}$



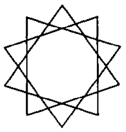
$\{\frac{9}{2}\}$



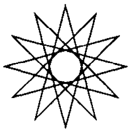
$\{\frac{9}{3}\}$



$\{\frac{9}{4}\}$



$\{\frac{10}{3}\}$



$\{\frac{12}{5}\}$

A star polygon $\{p/q\}$, with p, q POSITIVE INTEGERS, is a figure formed by connecting with straight lines every qth point out of p regularly spaced points lying on a CIRCUMFERENCE. The number q is called the DENSITY of the star polygon. Without loss of generality, take $q < p/2$.

The usual definition (Coxeter 1969) requires p and q to be RELATIVELY PRIME. However, the star polygon can also be generalized to the STAR FIGURE (or "improper" star polygon) when p and q share a common divisor (Savio and Suryanaroyan 1993). For such a figure, if all points are not connected after the first pass, i.e., if $(p,q) \neq 1$, then start with the first unconnected point and repeat the procedure. Repeat until all points are connected. For $(p,q) \neq 1$, the $\{p/q\}$ symbol can be factored as

$$\left\{\frac{p}{q}\right\} = n\left\{\frac{p}{q'}\right\}, \tag{1}$$

where

$$p' \equiv \frac{p}{n} \tag{2}$$

$$q' \equiv \frac{q}{n}, \tag{3}$$

to give n $\{p'/q'\}$ figures, each rotated by $2\pi/p$ radians, or $360°/p$.

If $q = 1$, a REGULAR POLYGON $\{p\}$ is obtained. Special cases of $\{p/q\}$ include $\{5/2\}$ (the PENTAGRAM), $\{6/2\}$ (the HEXAGRAM, or STAR OF DAVID), $\{8/2\}$ (the STAR OF LAKSHMI), $\{8/3\}$ (the OCTAGRAM), $\{10/3\}$ (the DECAGRAM), and $\{12/5\}$ (the DODECAGRAM).

The star polygons were first systematically studied by Thomas Bradwardine.

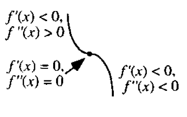
State Space

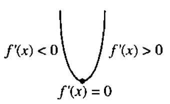
The measurable space $(S', \mathbb{S}')$ into which a RANDOM VARIABLE from a PROBABILITY SPACE is a measurable function.

see also PROBABILITY SPACE, RANDOM VARIABLE

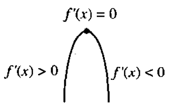
Stationary Point



stationary point



minimum



maximum

A point x_0 at which the DERIVATIVE of a FUNCTION $f(x)$ vanishes,

$$f'(x_0) = 0.$$

A stationary point may be a MINIMUM, MAXIMUM, or INFLECTION POINT.

see also CRITICAL POINT, DERIVATIVE, EXTREMUM, FIRST DERIVATIVE TEST, INFLECTION POINT, MAXIMUM, MINIMUM, SECOND DERIVATIVE TEST

Stationary Tangent

see INFLECTION POINT

Stationary Value

The value at a STATIONARY POINT.

Statistic

A function of one or more random variables.

see also ANDERSON-DARLING STATISTIC, KUIPER STATISTIC, VARIATE

Statistical Test

A test used to determine the statistical SIGNIFICANCE of an observation. Two main types of error can occur:

1. A TYPE I ERROR occurs when a false negative result is obtained in terms of the NULL HYPOTHESIS by obtaining a *false positive measurement.*
2. A TYPE II ERROR occurs when a false positive result is obtained in terms of the NULL HYPOTHESIS by obtaining a *false negative measurement.*

The probability that a statistical test will be positive for a true statistic is sometimes called the test's SENSITIVITY, and the probability that a test will be negative for a negative statistic is sometimes called the SPECIFICITY. The following table summarizes the names given to the various combinations of the actual state of affairs and observed test results.

result	name
true positive result	sensitivity
false negative result	1 − sensitivity
true negative result	specificity
false positive result	1 − specificity

Multiple-comparison corrections to statistical tests are used when several statistical tests are being performed simultaneously. For example, let's suppose you were measuring leg length in eight different lizard species and wanted to see whether the MEANS of any pair were different. Now, there are $8!/2!6! = 28$ pairwise comparisons possible, so even if all of the *population* means are equal, it's quite likely that at least one pair of sample means would differ significantly at the 5% level. An ALPHA VALUE of 0.05 is therefore appropriate for each individual comparison, but not for the set of *all* comparisons.

In order to avoid a lot of spurious positives, the ALPHA VALUE therefore needs to be lowered to account for the number of comparisons being performed. This is a correction for multiple comparisons. There are *many* different ways to do this. The simplest, and the most conservative, is the BONFERRONI CORRECTION. In practice, more people are more willing to accept false positives (false rejection of NULL HYPOTHESIS) than false negatives (false acceptance of NULL HYPOTHESIS), so less conservative comparisons are usually used.

Staudt-Clausen Theorem

see VON STAUDT-CLAUSEN THEOREM

Steenrod Algebra

The Steenrod algebra has to do with the COHOMOLOGY operations in singular COHOMOLOGY with INTEGER mod 2 COEFFICIENTS. For every $n \in \mathbb{Z}$ and $i \in \{0,1,2,3,\ldots\}$ there are natural transformations of FUNCTORS

$$Sq^i : H^n(\bullet;\mathbb{Z}_2) \to H^{n+i}(\bullet;\mathbb{Z}_2)$$

satisfying:

1. $Sq^i = 0$ for $i > n$.
2. $Sq^n(x) = x \smile x$ for all $x \in H^n(X,A;\mathbb{Z}_2)$ and all pairs (X,A).
3. $Sq^0 = id_{H^n(\bullet;\mathbb{Z}_2)}$.
4. The Sq^i maps commute with the coboundary maps in the long exact sequence of a pair. In other words,

   $$Sq^i : H^*(\bullet;\mathbb{Z}_2) \to H^{*+i}(\bullet;\mathbb{Z}_2)$$

   is a degree i transformation of cohomology theories.
5. (CARTAN RELATION)

   $$Sq^i(x \smile y) = \Sigma_{j+k=i} Sq^j(x) \smile Sq^k(y).$$

6. (ADEM RELATIONS) For $i < 2j$,

   $$Sq^i \circ Sq^j(x) = \Sigma_{k=0}^{\lfloor i \rfloor} \binom{j-k-1}{i-2k} Sq^{i+j-k} \circ Sq^k(x).$$

7. $Sq^i \circ \Sigma = \Sigma \circ Sq^i$ where Σ is the cohomology suspension isomorphism.

The existence of these cohomology operations endows the cohomology ring with the structure of a MODULE over the Steenrod algebra $\mathcal{A}$, defined to be $T(F_{\mathbb{Z}_2}\{Sq^i : i \in \{0,1,2,3,\ldots\}\})/R$, where $F_{\mathbb{Z}_2}(\bullet)$ is the free module functor that takes any set and sends it to the free $\mathbb{Z}_2$ module over that set. We think of $F_{\mathbb{Z}_2}\{Sq^i : i \in \{0,1,2,\ldots\}\}$ as being a graded $\mathbb{Z}_2$ module, where the i-th gradation is given by $\mathbb{Z}_2 \cdot Sq^i$. This makes the tensor algebra $T(F_{\mathbb{Z}_2}\{Sq^i : i \in \{0,1,2,3,\ldots\}\})$ into a GRADED ALGEBRA over $\mathbb{Z}_2$. R is the IDEAL generated by the elements $Sq^i Sq^j + \Sigma_{k=0}^{\lfloor i \rfloor} \binom{j-k-1}{i-2k} Sq^{i+j-k} Sq^k$ and

$1 + Sq^0$ for $0 < i < 2j$. This makes $\mathcal{A}$ into a graded $\mathbb{Z}_2$ algebra.

By the definition of the Steenrod algebra, for any SPACE (X, A), $H^*(X, A; \mathbb{Z}_2)$ is a MODULE over the Steenrod algebra $\mathcal{A}$, with multiplication induced by $Sq^i \cdot x \equiv Sq^i(x)$. With the above definitions, cohomology with COEFFICIENTS in the RING $\mathbb{Z}_2$, $H^*(\bullet; \mathbb{Z}_2)$ is a FUNCTOR from the category of pairs of TOPOLOGICAL SPACES to graded modules over $\mathcal{A}$.

Steenrod-Eilenberg Axioms

see EILENBERG-STEENROD AXIOMS

Steenrod's Realization Problem

When can homology classes be realized as the image of fundamental classes of MANIFOLDS? The answer is known, and singular BORDISM GROUPS provide insight into this problem.

see also BORDISM GROUP, MANIFOLD

Steepest Descent Method

An ALGORITHM for calculating the GRADIENT $\nabla f(\mathbf{P})$ of a function at an n-D point $\mathbf{P}$. The steepest descent method starts at a point $\mathbf{P}_0$ and, as many times as needed, moves from $\mathbf{P}_i$ to $\mathbf{P}_{i+1}$ by minimizing along the line extending from $\mathbf{P}_i$ in the direction of $-\nabla f(\mathbf{P}_i)$, the local downhill gradient. This method has the severe drawback of requiring a great many iterations for functions which have long, narrow valley structures. In such cases, a CONJUGATE GRADIENT METHOD is preferable.

see also CONJUGATE GRADIENT METHOD, GRADIENT

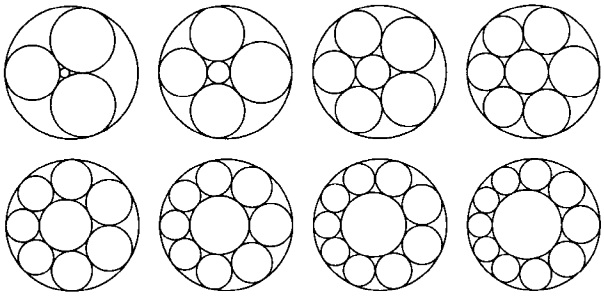
Steiner Chain



Given two nonconcentric CIRCLES with one interior to the other, if small TANGENT CIRCLES can be inscribed around the region between the two CIRCLES such that the final CIRCLE is TANGENT to the first, the CIRCLES form a Steiner chain.

The simplest way to construct a Steiner chain is to perform an INVERSION on a symmetrical arrangement on n circles packed between a central circle of radius b and an outer concentric circle of radius a. In this arrangement,

$$\sin\left(\frac{\pi}{n}\right)=\frac{a-b}{a+b}, \tag{1}$$

so the ratio of the radii for the small and large circles is

$$\frac{b}{a}=\frac{1-\sin\left(\frac{\pi}{n}\right)}{1+\sin\left(\frac{\pi}{n}\right)}. \tag{2}$$

To transform the symmetrical arrangement into a Steiner chain, find an INVERSION CENTER which transforms two centers initially offset by a fixed distance c to the same point. This can be done by equating

$$\frac{k^2x}{x^2-a^2}=\frac{k^2(x-c)}{(x-c)^2-b^2}, \tag{3}$$

giving the offset of the inversion center from the large circle's center as

$$x=\frac{a^2-b^2+c^2\pm\sqrt{(a^2-b^2+c^2)^2-4a^2c^2}}{2c}. \tag{4}$$

Plugging in a fixed value of a fixes b, which therefore determines x for a given c. Equivalently, a Steiner chain results whenever the INVERSIVE DISTANCE between the two original circles is given by

$$\delta=2\ln\left[\sec\left(\frac{\pi}{n}\right)+\tan\left(\frac{\pi}{n}\right)\right] \tag{5}$$

$$=2\ln\left[\tan\left(\frac{\pi}{4}+\frac{\pi}{2n}\right)\right] \tag{6}$$

(Coxeter and Greitzer 1967). The centers of the circles in a Steiner chain lie on an ELLIPSE (Ogilvy 1990, p. 57).

STEINER'S PORISM states that if a Steiner chain is formed from one starting circle, then a Steiner chain is also formed from any other starting circle.

Steiner Construction

A construction done using only a STRAIGHTEDGE. The PONCELET-STEINER THEOREM proves that all constructions possible using a COMPASS and STRAIGHTEDGE are possible using a STRAIGHTEDGE alone, as long as a fixed CIRCLE and its center, two intersecting CIRCLES without their centers, or three nonintersecting CIRCLES are drawn beforehand.

Steiner's Ellipse

Let $\alpha' : \beta' : \gamma'$ be the ISOTOMIC CONJUGATE POINT of a point with TRILINEAR COORDINATES $\alpha : \beta : \gamma$. The isotomic conjugate of the LINE AT INFINITY having trilinear equation

$$a\alpha+b\beta+c\gamma=0$$

is

$$\frac{\beta'\gamma'}{a}+\frac{\gamma'\alpha'}{b}+\frac{\alpha'\beta'}{c}=0,$$

known as Steiner's ellipse (Vandeghen 1965).

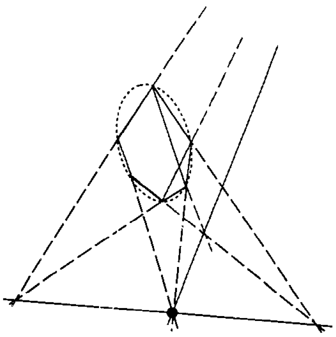
Steiner Points

There are two different types of points known as Steiner points.

The point of CONCURRENCE of the three lines drawn through the VERTICES of a TRIANGLE PARALLEL to the corresponding sides of the first BROCARD TRIANGLE. It lies on the CIRCUMCIRCLE opposite the TARRY POINT and has TRIANGLE CENTER FUNCTION

$$\alpha = bc(a^2 - b^2)(a^2 - c^2).$$

The BRIANCHON POINT for KIEPERT'S PARABOLA is the Steiner point. The LEMOINE POINT K is the Steiner point of the first BROCARD TRIANGLE. The SIMSON LINE of the Steiner point is PARALLEL to the line OK, when O is the CIRCUMCENTER and K is the LEMOINE POINT.



If triplets of opposites sides on a CONIC SECTION in PASCAL'S THEOREM are extended for all permutations of VERTICES, 60 PASCAL LINES are produced. The 20 points of their 3 by 3 intersections are called Steiner points.

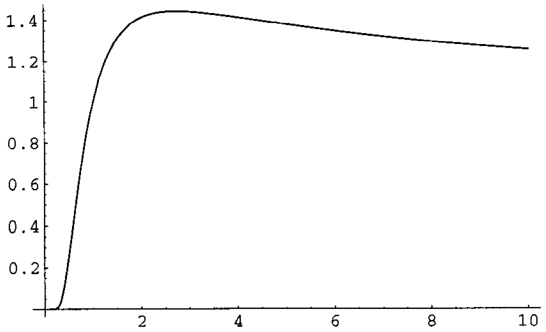
Steiner's Problem



For what value of x is $f(x) = x^{1/x}$ a MAXIMUM? The maximum occurs at $x = e$, where

$$f'(x) = x^{-2+1/x}(1 - \ln x) = 0,$$

which gives a maximum of

$$e^{1/e} = 1.444667861\ldots.$$

The function has an inflection point at $x = 0.581933\ldots$, where

$$f''(x) = x^{-4+1/x}[1 - 3x + (\ln x)(2x - 2 + \ln x)] = 0.$$

see also FERMAT'S PROBLEM

Steiner Quadruple System

A Steiner quadruple system is a STEINER SYSTEM $S(t = 3, k = 4, v)$, where S is a v-set and B is a collection of k-sets of S such that every t-subset of S is contained in exactly one member of B. Barrau (1908) established the uniqueness of $S(3,4,8)$,

1	2	4	8	3	5	6	7
2	3	5	8	1	4	6	7
3	4	6	8	1	2	5	7
4	5	7	8	1	2	3	6
1	5	6	8	2	3	4	7
2	6	7	8	1	3	4	5
1	3	7	8	2	4	5	6

and $S(3,4,10)$

1	2	4	5	1	2	3	7	1	3	5	8
2	3	5	6	2	3	4	8	2	4	6	9
3	4	6	7	3	4	5	9	3	5	7	0
4	5	7	8	4	5	6	0	1	4	6	8
5	6	8	9	1	5	6	7	2	5	7	9
6	7	9	0	2	6	7	8	3	6	8	0
1	7	8	0	3	7	8	9	1	4	7	9
1	2	8	9	4	8	9	0	2	5	8	0
2	3	9	0	1	5	9	0	1	3	6	9
1	3	4	0	1	2	6	0	2	4	7	0

Fitting (1915) subsequently constructed the cyclic systems $S(3,4,26)$ and $S(3,4,34)$, and Bays and de Weck (1935) showed the existence of at least one $S(3,4,14)$. Hanani (1960) proved that a NECESSARY and SUFFICIENT condition for the existence of an $S(3,4,v)$ is that $v \equiv 2$ or $4 \pmod 6$.

The number of nonisomorphic steiner quadruple systems of orders 8, 10, 14, and 16 are 1, 1, 4 (Mendelsohn and Hung 1972), and at least 31,021 (Lindner and Rosa 1976).

Steiner's Segment Problem

Given n points, find the line segments with the shortest possible total length which connect the points. The segments need not necessarily be straight from one point to another.

For three points, if all ANGLES are less than 120°, then the line segments are those connecting the three points to a central point P which makes the ANGLES $\langle A \rangle\, PB$, $\langle B \rangle\, PC$, and $\langle C \rangle\, PA$ all 120°. If one ANGLE is greater that 120°, then P coincides with the offending ANGLE.

For four points, P is the intersection of the two diagonals, but the required minimum segments are not necessarily these diagonals.

A modified version of the problem is, given two points, to find the segments with the shortest total length connecting the points such that each branch point may be connected to only three segments. There is no general solution to this version of the problem.

Steiner Set

Three sets of three LINES such that each line is incident with two from both other sets.

see also SOLOMON'S SEAL LINES, STEINER POINTS, STEINER TRIPLE SYSTEM

Steiner Surface

A projection of the Veronese Surface into 3-D (which must contain singularities) is called a Steiner surface. A classification of Steiner surfaces allowing complex parameters and projective transformations was accomplished in the 19th century. The surfaces obtained by restricting to real parameters and transformations were classified into 10 types by Coffman *et al.* (1996). Examples of Steiner surfaces include the Roman Surface (Coffman type 1) and Cross-Cap (type 3).

The Steiner surface of type 2 is given by the implicit equation

$$x^2y^2 - x^2z^2 + y^2z^2 - xyz = 0,$$

and can be transformed into the Roman Surface or Cross-Cap by a complex projective change of coordinates (but not by a real transformation). It has two pinch points and three double lines and, unlike the Roman Surface or Cross-Cap, is not compact in any affine neighborhood.

The Steiner surface of type 4 has the implicit equation

$$y^2 - 2xy^2 - xz^2 + x^2y^2 + x^2z^2 - z^4 = 0,$$

and two of the three double lines of surface 2 coincide along a line where the two noncompact "components" are tangent.

Steiner System

A Steiner system is a set X of v points, and a collection of subsets of X of size k (called blocks), such that any t points of X are in exactly one of the blocks. The special case $t = 2$ and $k = 3$ corresponds to a so-called Steiner Triple System. For a Projective Plane, $v = n^2 + n + 1$, $k = n + 1$, $t = 2$, and the blocks are simply lines.

Steiner's Theorem

Let Lines x and y join a variable point on a Conic Section to two fixed points on the same Conic Section. Then x and y are Projectively related.

see also Conic Section, Projection

Steiner Triple System

Let X be a set of $v \geq 3$ elements together with a set B of 3-subset (triples) of X such that every 2-Subset of X occurs in exactly one triple of B. Then B is called a Steiner triple system and is a special case of a Steiner System with $t = 2$ and $k = 3$. A Steiner triple system $S(v) = S(v, k = 3, \lambda = 1)$ of order v exists Iff $v \equiv 1, 3 \pmod 6$ (Kirkman 1847). In addition, if Steiner triple systems S_1 and S_2 of orders v_1 and v_2 exist, then so does a Steiner triple system S of order v_1v_2 (Ryser 1963, p. 101).

Examples of Steiner triple systems $S(v)$ of small orders v are

$$\begin{aligned}
S_3 &= \{\{1,2,3\}\} \\
S_7 &= \{\{1,2,4\},\{2,3,5\},\{3,4,6\},\{4,5,7\}, \\
&\quad \{5,6,1\},\{6,7,2\},\{7,1,3\}\} \\
S_9 &= \{\{1,2,3\},\{4,5,6\},\{7,8,9\},\{1,4,7\}, \\
&\quad \{2,5,8\},\{3,6,9\},\{1,5,9\},\{2,6,7\}\}.
\end{aligned}$$

The number of nonisomorphic Steiner triple systems $S(v)$ of orders $v = 7, 9, 13, 15, 19, \ldots$ (i.e., $6k + 1, 3$) are 1, 1, 20, 80, $> 1.1 \times 10^9$, … (Colbourn and Dinitz 1996, pp. 14–15; Sloane's A030129). $S(7)$ is the same as the finite Projective Plane of order 2. $S(9)$ is a finite Affine Plane which can be constructed from the array

$$\begin{array}{ccc} a & b & c \\ d & e & f. \\ g & h & i \end{array}$$

One of the two $S(13)$s is a finite Hyperbolic Plane. The 80 Steiner triple systems $S(15)$ have been studied by Tonchev and Weishaar (1997). There are more than 1.1×10^9 Steiner triple systems of order 19 (Stinson and Ferch 1985; Colbourn and Dinitz 1996, p. 15).

Steinerian Curve

The LOCUS of points whose first POLARS with regard to the curves of a linear net have a common point. It is also the LOCUS of points of CONCURRENCE of line POLARS of points of the JACOBIAN CURVE. It passes through all points common to all curves of the system and is of order $3(n-1)^2$.

see also CAYLEYIAN CURVE, JACOBIAN CURVE

References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, p. 150, 1959.

Steinhaus-Moser Notation

A NOTATION for LARGE NUMBERS defined by Steinhaus (1983, pp. 28–29). In this notation, $\bigtriangleup\!\!\!\!\!{\scriptstyle n}$ denotes n^n, $\boxed{n}$ denotes "n in n TRIANGLES," and ⓝ denotes "n in n SQUARES." A modified version due to Moser eliminates the circle notation, continuing instead with POLYGONS of ever increasing size, so n in a PENTAGON is n with n SQUARES around it, etc.

see also CIRCLE NOTATION, LARGE NUMBER, MEGA, MOSER

References

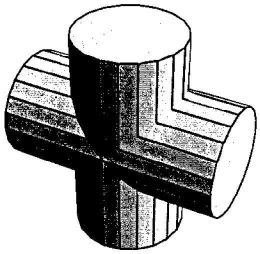
Steinhaus, H. *Mathematical Snapshots, 3rd American ed.* New York: Oxford University Press, 1983.

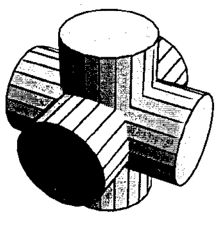
Steinitz's Theorem

A GRAPH G is the edge graph of a POLYHEDRON IFF G is a SIMPLE, PLANAR GRAPH which is 3-connected.

see also PLANAR GRAPH, SIMPLE GRAPH

Steinmetz Solid





The solid common to two (or three) right circular CYLINDERS of equal RADII intersecting at RIGHT ANGLES is called the Steinmetz solid. (Two CYLINDERS intersecting at RIGHT ANGLES are sometimes called a BICYLINDER, and three intersecting CYLINDERS a TRICYLINDER.)

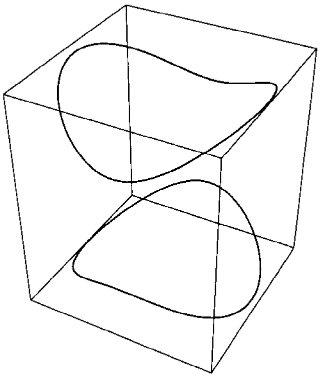
The VOLUME common to two intersecting right CYLINDERS of RADIUS r is

$$V_2(r,r) = \tfrac{16}{3}r^3. \qquad (1)$$

If the two right CYLINDERS are of *different* RADII a and b with $a > b$, then the VOLUME common to them is

$$V_2(a,b) = \tfrac{8}{3}a[(a^2+b^2)E(k) - (a^2-b^2)K(k)], \qquad (2)$$

where $K(k)$ is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND, $E(k)$ is the complete ELLIPTIC INTEGRAL OF THE SECOND KIND, and $k \equiv b/a$ is the MODULUS.



The curves of intersection of two cylinders of RADII a and b, shown above, are given by the parametric equations

$$x(t) = a\cos t \qquad (3)$$

$$y(t) = a\sin t \qquad (4)$$

$$z(t) = \pm\sqrt{b^2 - a^2\sin^2 t} \qquad (5)$$

(Gray 1993).

The VOLUME common to two ELLIPTIC CYLINDERS

$$\frac{x^2}{a^2} + \frac{z^2}{c^2} = 1 \qquad \frac{y^2}{b^2} + \frac{z^2}{c'^2} = 1 \qquad (6)$$

with $c < c'$ is

$$V_2(a,c;b,c') = \frac{8ab}{3c}[(c'^2+c^2)E(k) - (c'^2-c^2)K(k)], \quad (7)$$

where $k = c/c'$ (Bowman 1961, p. 34).

For three CYLINDERS of RADII r intersecting at RIGHT ANGLES, the VOLUME of intersection is

$$V_3(r,r,r) = 8(2-\sqrt{2})r^3. \qquad (8)$$

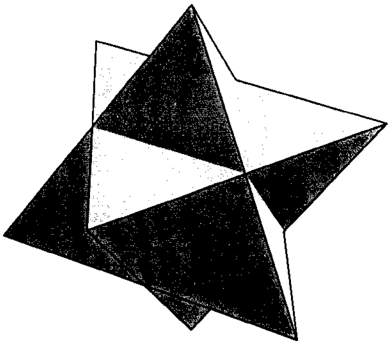
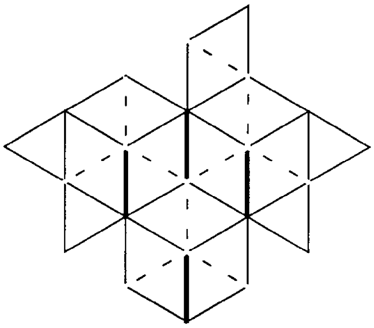
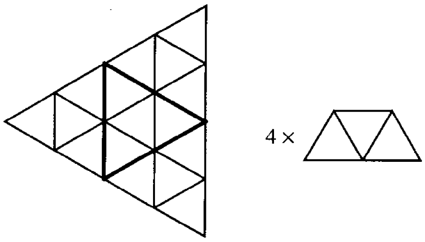
Stella Octangula

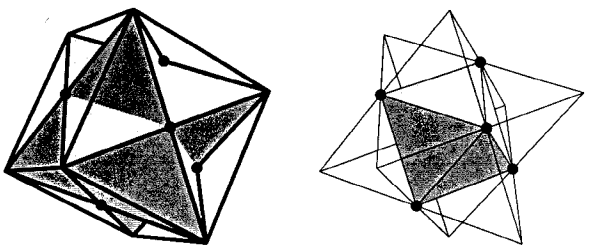


A POLYHEDRON COMPOUND composed of a TETRAHEDRON and its RECIPROCAL (a second TETRAHEDRON rotated 180° with respect to the first). The stella octangula is also called a STELLATED TETRAHEDRON. It can be constructed using the following NET by cutting along the solid lines, folding back along the plain lines, and folding forward along the dotted lines.



Another construction builds a single TETRAHEDRON, then attaches four tetrahedral caps, one to each face.





The edges of the two tetrahedra form the 12 DIAGONALS of a CUBE. The solid common to both tetrahedra is an OCTAHEDRON (Ball and Coxeter 1987).

Stellated Polyhedron

A convex regular POLYHEDRON. Stellated polyhedra include the KEPLER-POINSOT SOLIDS, which consist of three DODECAHEDRON STELLATIONS and one of the ICOSAHEDRON STELLATIONS. Coxeter (1982) shows that 59 ICOSAHEDRON STELLATIONS exist. The CUBE and the TETRAHEDRON cannot be stellated. The OCTAHEDRON has only one stellation, the STELLA OCTANGULA which is a compound of two TETRAHEDRA.

There are therefore a total of $3 + 1 + (59 - 1) + 1 = 63$ stellated POLYHEDRA, although some are COMPOUND POLYHEDRA and therefore not UNIFORM POLYHEDRA. The set of all possible EDGES of the stellations can be obtained by finding all intersections on the facial planes.

Stem-and-Leaf Diagram

The "stem" is a column of the data with the last digit removed. The final digits of each column are placed next to each other in a row next to the appropriate column. Then each row is sorted in numerical order. This diagram was invented by John Tukey.

Step Function

A function on the REALS $\mathbb{R}$ is a step function if it can be written as a finite linear combination of semi-open intervals $[a,b)\subseteq\mathbb{R}$. Therefore, a step function f can be written as

$$f(x)=\alpha_1 f_1(x)+\cdots+\alpha_n f_n(x),$$

where $\alpha_i\in\mathbb{R}$, $f_i(x)=1$ if $x\in[a_i,b_i)$ and 0 otherwise, for $i=1,\ldots,n$.

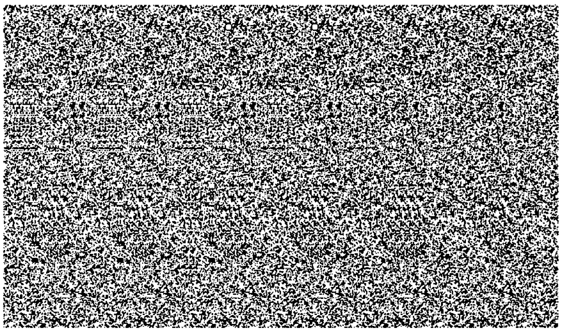
Steradian

The unit of SOLID ANGLE. The SOLID ANGLE corresponding to all of space being subtended is 4π steradian.

see also RADIAN, SOLID ANGLE

Stereogram



A plane image or pair of 2-D images which, when appropriately viewed using both eyes, produces an image which appears to be three-dimensional. By taking a pair of photographs from slightly different angles and then allowing one eye to view each image, a stereogram is not difficult to produce.

Amazingly, it turns out that the 3-D effect can be produced by both eyes looking at a *single* image by defocusing the eyes at a certain distance. Such stereograms are called "random-dot stereograms."

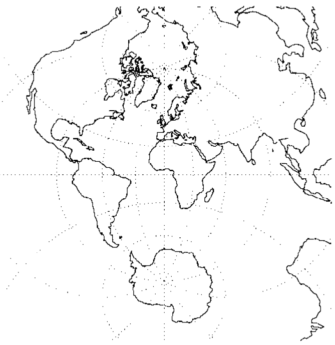
Stereographic Projection



A MAP PROJECTION in which GREAT CIRCLES are CIRCLES and LOXODROMES are LOGARITHMIC SPIRALS.

$$x = k\cos\phi\sin(\lambda - \lambda_0) \tag{1}$$
$$y = k[\cos\phi_1\sin\phi - \sin\phi_1\cos\phi\cos(\lambda - \lambda_0)], \tag{2}$$

where

$$k = \frac{2}{1 + \sin\phi_1\sin\phi + \cos\phi_1\cos\phi\cos(\lambda - \lambda_0)}. \tag{3}$$

The inverse FORMULAS are given by

$$\phi = \sin^{-1}\left(\cos c\sin\phi_1 + \frac{y\sin c\cos\phi_1}{\rho}\right) \tag{4}$$
$$\lambda = \lambda_0 + \tan^{-1}\left(\frac{x\sin c}{\rho\cos\phi_1\cos c - y\sin\phi_1\sin c}\right), \tag{5}$$

where

$$\rho = \sqrt{x^2 + y^2} \tag{6}$$
$$c = 2\tan^{-1}(\tfrac{1}{2}\rho). \tag{7}$$

Stick Number

Let the stick number $s(K)$ of a KNOT K be the least number of straight sticks needed to make a KNOT K. The smallest stick number of any KNOT is $s(T) = 6$, where T is the TREFOIL KNOT. If J and K are KNOTS, then

$$s(J + K) \leq s(J) + s(K) + 1.$$

For a nontrivial KNOT K, let $c(K)$ be the CROSSING NUMBER (i.e., the least number of crossings in any projection of K). Then

$$\tfrac{1}{2}[5+\sqrt{25+8(c(K)-2)}] \leq s(K) \leq 2c(K).$$

The following table gives the stick number for some common knots.

Knot	s
trefoil knot	6
Whitehead link	8

Stiefel Manifold

The Stiefel manifold of ORTHONORMAL k-frames in $\mathbb{R}^n$ is the collection of vectors $(v_1, \ldots, v_k)$ where v_i is in $\mathbb{R}^n$ for all i, and the k-tuple $(v_1, \ldots, v_k)$ is ORTHONORMAL. This is a submanifold of $\mathbb{R}^{nk}$, having DIMENSION $nk - (k+1)k/2$.

Sometimes the "orthonormal" condition is dropped in favor of the mildly weaker condition that the k-tuple $(v_1, \ldots, v_k)$ is linearly independent. Usually, this does not affect the applications since Stiefel manifolds are usually considered only during HOMOTOPY THEORETIC considerations. With respect to HOMOTOPY THEORY, the two definitions are more or less equivalent since GRAM-SCHMIDT ORTHONORMALIZATION gives rise to a smooth deformation retraction of the second type of Stiefel manifold onto the first.

see also GRASSMANN MANIFOLD

Stiefel-Whitney Class

The ith Stiefel-Whitney class of a REAL VECTOR BUNDLE (or TANGENT BUNDLE or a REAL MANIFOLD) is in the ith cohomology group of the base SPACE involved. It is an OBSTRUCTION to the existence of $(n-i+1)$ REAL linearly independent VECTOR FIELDS on that VECTOR BUNDLE, where n is the dimension of the FIBER. Here, OBSTRUCTION means that the ith Stiefel-Whitney class being NONZERO implies that there do *not* exist $(n-i+1)$ everywhere linearly dependent VECTOR FIELDS (although the Stiefel-Whitney classes are not always the OBSTRUCTION).

In particular, the nth Stiefel-Whitney class is the obstruction to the existence of an everywhere NONZERO VECTOR FIELD, and the first Stiefel-Whitney class of a MANIFOLD is the obstruction to orientability.

see also CHERN CLASS, OBSTRUCTION, PONTRYAGIN CLASS, STIEFEL-WHITNEY NUMBER

Stiefel-Whitney Number

The Stiefel-Whitney number is defined in terms of the STIEFEL-WHITNEY CLASS of a MANIFOLD as follows. For any collection of STIEFEL-WHITNEY CLASSES such that their cup product has the same DIMENSION as the MANIFOLD, this cup product can be evaluated on the MANIFOLD's FUNDAMENTAL CLASS. The resulting number is called the PONTRYAGIN NUMBER for that combination of Pontryagin classes.

The most important aspect of Stiefel-Whitney numbers is that they are COBORDISM invariant. Together, PONTRYAGIN and Stiefel-Whitney numbers determine an oriented MANIFOLD's COBORDISM class.

see also CHERN NUMBER, PONTRYAGIN NUMBER, STIEFEL-WHITNEY CLASS

Stieltjes Constants

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Expanding the RIEMANN ZETA FUNCTION about $z = 1$ gives

$$\zeta(z) = \frac{1}{z-1} + \sum_{n=0}^{\infty} \frac{(-1)^n}{n!}\gamma_n(z-1)^n, \qquad (1)$$

where

$$\gamma_n \equiv \lim_{m\to\infty}\left[\sum_{k=1}^{m}\frac{(\ln k)^n}{k} - \frac{(\ln m)^{n+1}}{n+1}\right]. \qquad (2)$$

An alternative definition is given by

$$\gamma_n' \equiv \frac{(-1)^n}{n!}\gamma_n. \qquad (3)$$

The case $n = 0$ gives the EULER-MASCHERONI CONSTANT γ. The first few numerical values are given in the following table.

n	γ_n
0	0.5772156649
1	−0.07281584548
2	−0.009690363192
3	0.002053834420
4	0.002325370065
5	0.0007933238173

Briggs (1955–1956) proved that there infinitely many γ_n of each SIGN. Berndt (1972) gave upper bounds of

$$|\gamma_n| < \begin{cases} \frac{4(n-1)!}{\pi^n} & \text{for } n \text{ even} \\ \frac{2(n-1)!}{\pi^n} & \text{for } n \text{ odd.} \end{cases} \tag{4}$$

Vacca (1910) proves that the EULER-MASCHERONI CONSTANT may be expressed as

$$\gamma = \sum_{k=1}^{\infty} \frac{(-1)^k}{k} \lfloor \lg k \rfloor, \tag{5}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION. Hardy (1912) gave the FORMULA

$$\frac{2\gamma_1}{\ln 2} = \sum_{k=1}^{\infty} \frac{(-1)^k}{k} [2 \lg k - \lfloor \lg(2k) \rfloor] \lfloor \lg k \rfloor. \tag{6}$$

Kluyver (1927) gave similar series for γ_n with $n > 1$.

A set of constants related to γ_n is

$$\delta_n \equiv \lim_{m\to\infty} \left[\sum_{k=1}^{m} (\ln k)^n - \int_1^m (\ln x)^n \, dx - \tfrac{1}{2}(\ln m)^n \right] \tag{7}$$

(Sitaramachandrarao 1986, Lehmer 1988).

Stieltjes Integral

The Stieltjes integral is a generalization of the RIEMANN INTEGRAL. Let $f(x)$ and $\alpha(x)$ be real-values bounded functions defined on a CLOSED INTERVAL $[a, b]$. Take a partition of the INTERVAL

$$a = x_0 < x_1 < x_2, \ldots < x_{n-1} < x_n = b, \tag{1}$$

and consider the Riemann sum

$$\sum_{i=0}^{n-1} f(\xi_i)[\alpha(x_{i+1}) - \alpha(x_i)] \tag{2}$$

with $\xi_i \in [x_i, x_{i+1}]$. If the sum tends to a fixed number I as $\max(x_{i+1} - x_i) \to 0$, then I is called the Stieltjes integral, or sometimes the RIEMANN-STIELTJES INTEGRAL. The Stieltjes integral of P with respect to F is denoted

$$\int P(x)\, dF(x), \tag{3}$$

where

$$\int P(x)\, dF(x) = \begin{cases} \int f(x)\, dx & \text{for } x \text{ continuous} \\ \sum_x f(x) & \text{for } x \text{ discrete.} \end{cases} \tag{4}$$

If P and F have a common point of discontinuity, then the integral does not exist. However, if the Stieltjes integral exists and F has a derivative F', then

$$\int P(x)\, dF(x) = \int P(x) F'(x)\, dx. \tag{5}$$

For enumeration of many of the integral's properties, see Dresher (1981, p. 105).

Stirling's Approximation

Stirling's approximation gives an approximate value for the FACTORIAL function $n!$ or the GAMMA FUNCTION $\Gamma(n)$ for $n \gg 1$. The approximation can most simply be derived for n an INTEGER by approximating the sum over the terms of the FACTORIAL with an INTEGRAL, so that

$$\ln n! = \ln 1 + \ln 2 + \ldots + \ln n = \sum_{k=1}^{n} \ln k \approx \int_1^n \ln x \, dx = [x \ln x - x]_1^n = n \ln n - n + 1 \approx n \ln n - n. \quad (1)$$

The equation can also be derived using the integral definition of the FACTORIAL,

$$n! = \int_0^\infty e^{-x} x^n \, dx. \quad (2)$$

Note that the derivative of the LOGARITHM of the integrand can be written

$$\frac{d}{dx} \ln(e^{-x} x^n) = \frac{d}{dx}(n \ln x - x) = \frac{n}{x} - 1. \quad (3)$$

The integrand is sharply peaked with the contribution important only near $x = n$. Therefore, let $x \equiv n + \xi$ where $\xi \ll n$, and write

$$\ln(x^n e^{-x}) = n \ln x - x = n \ln(n + \xi) - (n + \xi). \quad (4)$$

Now,

$$\ln(n+\xi) = \ln\left[n\left(1+\frac{\xi}{n}\right)\right] = \ln n + \ln\left(1+\frac{\xi}{n}\right) = \ln n + \frac{\xi}{n} - \frac{1}{2}\frac{\xi^2}{n^2} + \ldots, \quad (5)$$

so

$$\ln(x^n e^{-x}) = n \ln(n+\xi) - (n+\xi) = n \ln n + \xi - \frac{1}{2}\frac{\xi^2}{n} - n - \xi + \ldots = n \ln n - n - \frac{\xi^2}{2n} + \ldots. \quad (6)$$

Taking the EXPONENTIAL of each side then gives

$$x^n e^{-x} \approx e^{n \ln n} e^{-n} e^{-\xi^2/2n} = n^n e^{-n} e^{-\xi^2/2n}. \quad (7)$$

Plugging into the integral expression for $n!$ then gives

$$n! \approx \int_{-n}^{\infty} n^n e^{-n} e^{-\xi^2/2n} \, d\xi \approx n^n e^{-n} \int_{-\infty}^{\infty} e^{-\xi^2/2n} \, d\xi = n^n. \quad (8)$$

Evaluating the integral gives

$$n! \approx n^n e^{-n} \sqrt{2\pi n}, \quad (9)$$

$$\approx \sqrt{2\pi}\, n^{n+1/2} e^{-n}. \quad (10)$$

Taking the LOGARITHM of both sides then gives

$$\ln n! \approx n \ln n - n + \tfrac{1}{2}\ln(2\pi n) = (n + \tfrac{1}{2}) \ln n - n + \tfrac{1}{2}\ln(2\pi). \quad (11)$$

This is STIRLING'S SERIES with only the first term retained and, for large n, it reduces to Stirling's approximation

$$\ln n! \approx n \ln n - n. \quad (12)$$

Gosper notes that a better approximation to $n!$ (i.e., one which approximates the terms in STIRLING'S SERIES instead of truncating them) is given by

$$n! \approx \sqrt{(2n + \tfrac{1}{3})\pi}\, n^n e^{-n}. \quad (13)$$

This also gives a much closer approximation to the FACTORIAL of 0, $0! = 1$, yielding $\sqrt{\pi/3} \approx 1.02333$ instead of 0 obtained with the conventional Stirling approximation.

Stirling's Formula

see STIRLING'S SERIES

Stirling Number of the First Kind

The definition of the (signed) Stirling number of the first kind is a number $S_n^{(m)}$ such that the number of permutations of n elements which contain exactly m CYCLES is

$$(-1)^{n-m} S_n^{(m)}. \qquad (1)$$

This means that $S_n^{(m)} = 0$ for $m > n$ and $S_n^{(n)} = 1$. The GENERATING FUNCTION is

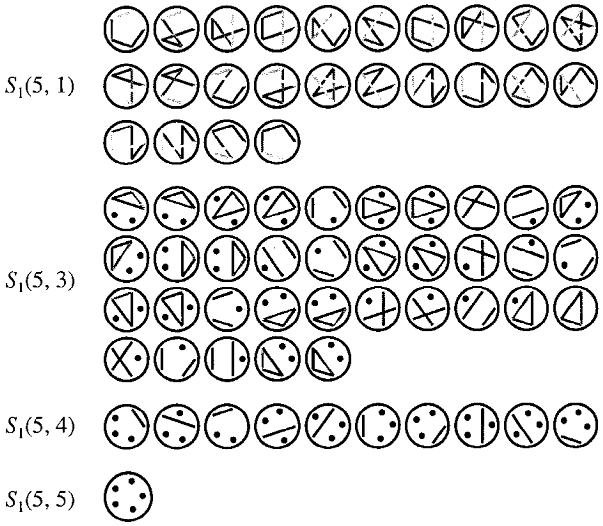
$$x(x-1)\cdots(x-n+1) = \sum_{m=0}^{n} S_n^{(m)} x^m. \qquad (2)$$

This is the Stirling number of the first kind returned by the *Mathematica*® (Wolfram Research, Champaign, IL) command `StirlingS1[n,m]`. The triangle of signed Stirling numbers of the first kind is

$$\begin{array}{c} 1 \\ -1 \quad 1 \\ 2 \quad -3 \quad 1 \\ -6 \quad 11 \quad 6 \quad 1 \\ 24 \quad -50 \quad 35 \quad -10 \quad 1 \end{array}$$

(Sloane's A008275).

The NONNEGATIVE version simply gives the number of PERMUTATIONS of n objects having m CYCLES (with cycles in opposite directions counted as distinct) and is obtained by taking the ABSOLUTE VALUE of the signed version. The nonnegative Stirling number of the first kind is denoted $S_1(n,m) = |S_n^{(m)}|$ or $\begin{bmatrix} n \\ m \end{bmatrix}$. Diagrams illustrating $S_1(5,1) = 24$, $S_1(5,3) = 35$, $S_1(5,4) = 10$, and $S_1(5,5) = 1$ (Dickau) are shown below.



The nonnegative Stirling numbers of the first kind satisfy the curious identity

$$\sum_{n=1}^{\infty}\left[\sum_{k=0}^{n-2}\frac{(e^x - x - 1)^{k+1} S_1(n, n-k)}{(k+1)!}\right] e^{-xn} = \ln(x+1) \qquad (3)$$

(Gosper) and have the GENERATING FUNCTION

$$(1+x)(1+2x)\cdots(1+nx) = \sum_{k=1}^{n} S_1(n,m)x^k \qquad (4)$$

and satisfy

$$_1(n+1,k) = nS_1(n,k) + S_1(n,k-1). \qquad (5)$$

The Stirling numbers can be generalized to nonintegral arguments (a sort of "Stirling polynomial") using the identity

$$\frac{\Gamma(j+h)}{j^h\Gamma(j)} = \sum_{k=0}^{\infty}\frac{S_1(h,h-k)}{j^k} = 1 + \frac{(h-1)h}{2j} + \frac{(h-2)(3h-1)(h-1)h}{24j^2} + \frac{(h-3)(h-2)(h-1)^2h^2}{48j^3} + \ldots, \qquad (6)$$

which is a generalization of an ASYMPTOTIC SERIES for a ratio of GAMMA FUNCTIONS $\Gamma(j+1/2)/\Gamma(j)$ (Gosper).

Stirling Number of the Second Kind

The number of ways of partitioning a set of n elements into m nonempty SETS (i.e., m BLOCKS), also called a STIRLING SET NUMBER. For example, the SET $\{1,2,3\}$ can be partitioned into three SUBSETS in one way: $\{\{1\},\{2\},\{3\}\}$; into two SUBSETS in three ways: $\{\{1,2\},\{3\}\}$, $\{\{1,3\},\{2\}\}$, and $\{\{1\},\{2,3\}\}$; and into one SUBSET in one way: $\{\{1,2,3\}\}$.

The Stirling numbers of the second kind are denoted $s_n^{(m)}$, $S_2(n,m)$, $s(n,m)$, or $\left\{ n \atop m \right\}$, so the Stirling numbers of the second kind for three elements are

$$s(3,1) = 1 \qquad (1)$$

$$s(3,2) = 3 \qquad (2)$$

$$s(3,3) = 1. \qquad (3)$$

Since a set of n elements can only be partitioned in a single way into 1 or n SUBSETS,

$$s(n,1) = s(n,n) = 1. \qquad (4)$$

The triangle of Stirling numbers of the second kind is

$$\begin{array}{ccccccccccc} &&&&& 1 &&&&& \\ &&&& 1 && 1 &&&& \\ &&& 1 && 3 && 1 &&& \\ && 1 && 7 && 6 && 1 && \\ & 1 && 15 && 25 && 10 && 1 & \\ 1 && 31 && 90 && 65 && 15 && 1 \end{array}$$

(Sloane's A008277).

The Stirling numbers of the second kind can be computed from the sum

$$s(n,k) = \frac{1}{k!}\sum_{i=0}^{k-1}(-1)^i\binom{k}{i}(k-i)^n, \qquad (5)$$

with $\binom{n}{k}$ a BINOMIAL COEFFICIENT, or the GENERATING FUNCTIONS

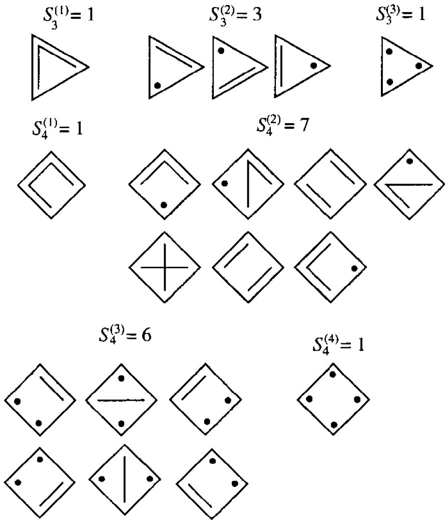
$$x^n = \sum_{m=0}^{n} s(n,m)x(x-1)\cdots(x-m+1), \qquad (6)$$

$$\sum_{n\geq k} s(n,k)\frac{x^n}{n!} = \frac{1}{k!}(e^x-1)^k, \qquad (7)$$

and

$$\frac{1}{(1-x)(1-2x)\cdots(1-kx)} = \sum_{n=1}^{k} s(n,k)x^n. \qquad (8)$$

The following diagrams (Dickau) illustrate the definition of the Stirling numbers of the second kind $s(n,m)$ for $n=3$ and 4.



Stirling numbers of the second kind obey the RECURRENCE RELATIONS

$$s(n,k) = s(n-1,k-1) + ks(n-1,k). \qquad (9)$$

An identity involving Stirling numbers of the second kind is

$$f(m,n) \equiv \sum_{k=1}^{\infty} k^n\left(\frac{m}{m+1}\right)^l = (m+1)\sum_{k=1}^{m} k!s(n,k)m^k. \qquad (10)$$

It turns out that $f(1,n)$ can have only 0, 2, or 6 as a last DIGIT (Riskin 1995).

Stirling's Series

The ASYMPTOTIC SERIES for the GAMMA FUNCTION is given by

$$\Gamma(z)=e^{-z}z^{z-1/2}\sqrt{2\pi}\left(1+\frac{1}{12z}+\frac{1}{288z^2}-\frac{139}{51840z^3}-\frac{571}{2488320z^4}+\ldots\right)\quad(1)$$

(Sloane's A001163 and A001164). The series for $z!$ is obtained by adding an additional factor of z,

$$z!=\Gamma(z+1)=e^{-z}z^{z+1/2}\sqrt{2\pi}\left(1+\frac{1}{12z}+\frac{1}{288z^2}-\frac{139}{51840z^3}-\frac{571}{2488320z^4}+\ldots\right).\quad(2)$$

The expansion of $\ln\Gamma(z)$ is what is usually called Stirling's series. It is given by the simple analytic expression

$$\ln\Gamma(z)=\sum_{n=1}^{\infty}\frac{B_{2n}}{2n(2n-1)z^{2n-1}}\quad(3)$$

$$=\tfrac{1}{2}\ln(2\pi)+(z+\tfrac{1}{2})\ln z-z+\frac{1}{12z}-\frac{1}{360z^3}+\frac{1}{1260z^5}-\ldots,\quad(4)$$

where B_n is a BERNOULLI NUMBER.

Stochastic Group

The GROUP of all nonsingular $n\times n$ STOCHASTIC MATRICES over a FIELD F. It is denoted $S(n,F)$. If p is PRIME and F is the GALOIS FIELD of ORDER $q=p^m$, $S(n,q)$ is written instead of $S(n,F)$. Particular examples include

$$\begin{aligned}S(2,2)&=\mathbb{Z}_2\\ S(2,3)&=S_3\\ S(2,4)&=A_4\\ S(3,2)&=S_4\\ S(2,5)&=\mathbb{Z}_4\times_\theta\mathbb{Z}_5,\end{aligned}$$

where $\mathbb{Z}_2$ is an ABELIAN GROUP, S_n are SYMMETRIC GROUPS on n elements, and $\times_\theta$ denotes the semidirect product with $\theta:\mathbb{Z}_4\to\mathrm{Aut}(\mathbb{Z}_5)$ (Poole 1995).

see also STOCHASTIC MATRIX

References

Poole, D. G. "The Stochastic Group." *Amer. Math. Monthly* **102**, 798–801, 1995.

Stochastic Matrix

A Stochastic matrix is the transition matrix for a finite MARKOV CHAIN, also called a MARKOV MATRIX. Elements of the matrix must be REAL NUMBERS in the CLOSED INTERVAL [0, 1].

A completely independent type of stochastic matrix is defined as a SQUARE MATRIX with entries in a FIELD F such that the sum of elements in each column equals 1. There are two nonsingular 2×2 STOCHASTIC MATRICES over $\mathbb{Z}_2$ (i.e., the integers mod 2),

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

There are six nonsingular stochastic 3×3 MATRICES over $\mathbb{Z}_3$,

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 2 & 1 \\ 2 & 0 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 2 & 1 \end{bmatrix}, \begin{bmatrix} 0 & 2 \\ 1 & 2 \end{bmatrix}, \begin{bmatrix} 1 & 2 \\ 0 & 2 \end{bmatrix}.$$

In fact, the set S of all nonsingular stochastic $n \times n$ matrices over a FIELD F forms a GROUP under MATRIX MULTIPLICATION. This GROUP is called the STOCHASTIC GROUP.

Poole, D. G. "The Stochastic Group." *Amer. Math. Monthly* **102**, 798–801, 1995.

Stochastic Process

A stochastic process is a family of RANDOM VARIABLES $\{x(t, \bullet), t \in \mathcal{J}\}$ from some PROBABILITY SPACE $(S, \mathbb{S}, P)$ into a STATE SPACE $(S', \mathbb{S}')$. Here, $\mathcal{J}$ is the INDEX SET of the process.

Stochastic Resonance

A stochastic resonance is a phenomenon in which a nonlinear system is subjected to a periodic modulated signal so weak as to be normally undetectable, but it becomes detectable due to resonance between the weak deterministic signal and stochastic NOISE. The earliest definition of stochastic resonance was the maximum of the output signal strength as a function of NOISE (Bulsara and Gammaitoni 1996).

Stokes' Theorem

For w a DIFFERENTIAL $(n-1)$-FORM with compact support on an oriented n-dimensional MANIFOLD M,

$$\int_M dw = \int_{\partial M} w, \tag{1}$$

where dw is the EXTERIOR DERIVATIVE of the differential form w. This connects to the "standard" GRADIENT, CURL, and DIVERGENCE THEOREMS by the following relations. If f is a function on $\mathbb{R}^3$,

$$\mathrm{grad}(f) = c^{-1}\, df, \tag{2}$$

where $c : \mathbb{R}^3 \to \mathbb{R}^{3*}$ (the dual space) is the duality isomorphism between a VECTOR SPACE and its dual, given by the Euclidean INNER PRODUCT on $\mathbb{R}^3$. If f is a VECTOR FIELD on a $\mathbb{R}^3$,

$$\mathrm{div}(f) = {}^*d^*c(f), \tag{3}$$

where $*$ is the HODGE STAR operator. If f is a VECTOR FIELD on $\mathbb{R}^3$,

$$\mathrm{curl}(f) = c^{-1*}dc(f). \tag{4}$$

With these three identities in mind, the above Stokes' theorem in the three instances is transformed into the GRADIENT, CURL, and DIVERGENCE THEOREMS respectively as follows. If f is a function on $\mathbb{R}^3$ and γ is a curve in $\mathbb{R}^3$, then

$$\int_\gamma \mathrm{grad}(f) \cdot dl = \int_\gamma df = f(\gamma(1)) - f(\gamma(0)), \tag{5}$$

which is the GRADIENT THEOREM. If $f:\mathbb{R}^3\to\mathbb{R}^3$ is a VECTOR FIELD and M an embedded compact 3-manifold with boundary in $\mathbb{R}^3$, then

$$\int_{\partial M} f\cdot dA = \int_{\partial M} {}^*cf = \int_M d{*}cf = \int_M \operatorname{div}(f)\,dV, \quad (6)$$

which is the DIVERGENCE THEOREM. If f is a VECTOR FIELD and M is an oriented, embedded, compact 2-MANIFOLD with boundary in $\mathbb{R}^3$, then

$$\int_{\partial M} f\,dl = \int_{\partial M} cf = \int_M dc(f) = \int_M \operatorname{curl}(f)\cdot dA, \quad (7)$$

which is the CURL THEOREM.

Physicists generally refer to the CURL THEOREM

$$\int_S (\nabla\times\mathbf{F})\cdot d\mathbf{a} = \int_{\partial S} \mathbf{F}\cdot d\mathbf{s} \qquad (8)$$

as Stokes' theorem.

Stolarsky-Harborth Constant

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Let $b(k)$ be the number of 1s in the BINARY expression of k. Then the number of ODD BINOMIAL COEFFICIENTS $\binom{k}{j}$ where $0\leq j\leq k$ is $2^{b(k)}$ (Glaisher 1899, Fine 1947). The number of ODD elements in the first n rows of PASCAL'S TRIANGLE is

$$f(n)=\sum_{k=0}^{n-1}2^{b(k)}. \qquad (1)$$

This function is well approximated by n^θ, where

$$\theta\equiv\frac{\ln 3}{\ln 2}=1.58496\ldots. \qquad (2)$$

Stolarsky and Harborth showed that

$$0.812556\leq\liminf_{n\to\infty}\frac{f(n)}{n^\theta} < 0.812557 < \limsup_{n\to\infty}\frac{f(n)}{n^\theta}=1. \qquad (3)$$

The value

$$SH=\liminf_{n\to\infty}\frac{f(n)}{n^\theta} \qquad (4)$$

is called the Stolarsky-Harborth constant.

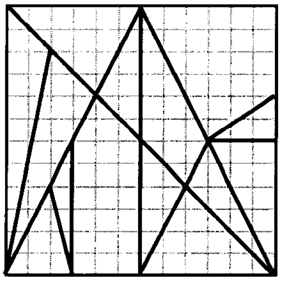
Stolarsky's Inequality

If $0\leq g(x)\leq 1$ and g is nonincreasing on the INTERVAL [0,1], then for all possible values of a and b,

$$\int_0^1 g(x^{1/(a+b)})\,dx \geq \int_0^1 g(x^{1/a})\,dx \int_0^1 g(x^{1/b})\,dx.$$

Stomachion



A DISSECTION game similar to TANGRAMS described in fragmentary manuscripts attributed to Archimedes and was referred to as the LOCULUS OF ARCHIMEDES (Archimedes' box) in Latin texts. The word Stomachion has as its root the Greek word for stomach. The game consisted of 14 flat pieces of various shapes arranged in the shape of a square. Like TANGRAMS, the object is to rearrange the pieces to form interesting shapes.

Størmer Number

A Størmer number is a POSITIVE INTEGER n for which the largest PRIME factor p of n^2+1 is at least $2n$. Every GREGORY NUMBER t_x can be expressed uniquely as a sum of t_ns where the ns are Størmer numbers. Conway and Guy (1996) give a table of Størmer numbers reproduced below (Sloane's A005529). In a paper on INVERSE TANGENT relations, Todd (1949) gives a similar compilation.

n	p	n	p	n	p	n	p	n	p
1	2	10	101	19	181	26	617	35	613
2	5	11	61	20	401	27	73	36	1297
4	17	12	29	22	97	28	157	37	137
5	13	14	197	23	53	29	421	39	761
6	37	15	113	24	577	33	109	40	1601
9	41	16	257	25	313	34	89	42	353

Strange Loop

A phenomenon in which, whenever movement is made upwards or downwards through the levels of some heirarchial system, the system unexpectedly arrives back where it started. Hofstadter (1987) uses the strange loop as a paradigm in which to interpret paradoxes in logic (such as GRELLING'S PARADOX and RUSSELL'S PARADOX) and calls a system in which a strange loop appears a TANGLED HIERARCHY.

see also GRELLING'S PARADOX, RUSSELL'S PARADOX, TANGLED HIERARCHY

Strangers

Two numbers which are RELATIVELY PRIME.

References
Le Lionnais, F. *Les nombres remarquables.* Paris: Hermann, p. 145, 1983.

Strassen Formulas

The usual number of scalar operations (i.e., the total number of additions and multiplications) required to perform $n \times n$ MATRIX MULTIPLICATION is

$$M(n) = 2n^3 - n^2 \tag{1}$$

(i.e., n^3 multiplications and $n^3 - n^2$ additions). However, Strassen (1969) discovered how to multiply two MATRICES in

$$S(n) = 7 \cdot 7^{\lg n} - 6 \cdot 4^{\lg n} \tag{2}$$

scalar operations, where lg is the LOGARITHM to base 2, which is less than $M(n)$ for $n > 654$. For n a power of two ($n = 2^k$), the two parts of (2) can be written

$$7 \cdot 7^{\lg n} = 7 \cdot 7^{\lg 2^k} = 7 \cdot 7^k = 7 \cdot 2^{k \lg 7} = 7(2^k)^{\lg 7} = 7n^{\lg 7} \tag{3}$$

$$6 \cdot 4^{\lg n} = 6 \cdot 4^{\lg 2^k} = 6 \cdot 4^{k \lg 2} = 6 \cdot 4^k = 6(2^k)^2 = 6n^2, \tag{4}$$

so (2) becomes

$$S(2^k) = 7n^{\lg 7} - 6n^2. \tag{5}$$

Two 2×2 matrices can therefore be multiplied

$$\mathsf{C} = \mathsf{AB} \tag{6}$$

$$\begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} \tag{7}$$

with only

$$S(2) = 7 \cdot 2^{\lg 7} - 6 \cdot 2^2 = 49 - 24 = 25 \tag{8}$$

scalar operations (as it turns out, seven of them are multiplications and 18 are additions). Define the seven products (involving a total of 10 additions) as

$$Q_1 \equiv (a_{11} + a_{22})(b_{11} + b_{22}) \tag{9}$$
$$Q_2 \equiv (a_{21} + a_{22})b_{11} \tag{10}$$
$$Q_3 \equiv a_{11}(b_{12} - b_{22}) \tag{11}$$
$$Q_4 \equiv a_{22}(-b_{11} + b_{21}) \tag{12}$$
$$Q_5 \equiv (a_{11} + a_{12})b_{22} \tag{13}$$
$$Q_6 \equiv (-a_{11} + a_{12})(b_{11} + b_{12}) \tag{14}$$
$$Q_7 \equiv (a_{12} - a_{22})(b_{21} + b_{22}). \tag{15}$$

Then the matrix product is given using the remaining eight additions as

$$c_{11} = Q_1 + Q_4 - Q_5 + Q_7 \tag{16}$$
$$c_{21} = Q_2 + Q_4 \tag{17}$$
$$c_{12} = Q_3 + Q_5 \tag{18}$$
$$c_{22} = Q_1 + Q_3 - Q_2 + Q_6 \tag{19}$$

(Strassen 1969, Press *et al.* 1989).

Matrix inversion of a 2×2 matrix A to yield $\mathsf{C} = \mathsf{A}^{-1}$ can also be done in fewer operations than expected using the formulas

$$R_1 \equiv {a_{11}}^{-1} \tag{20}$$
$$R_2 \equiv a_{21}R_1 \tag{21}$$
$$R_3 \equiv R_1 a_{12} \tag{22}$$
$$R_4 \equiv a_{21}R_3 \tag{23}$$
$$R_5 \equiv R_4 - a_{22} \tag{24}$$
$$R_6 \equiv {R_5}^{-1} \tag{25}$$
$$c_{12} = R_3 R_6 \tag{26}$$
$$c_{21} = R_6 R_2 \tag{27}$$
$$R_7 = R_3 c_{21} \tag{28}$$
$$c_{11} = R_1 - R_7 \tag{29}$$
$$c_{22} = -R_6 \tag{30}$$

(Strassen 1969, Press *et al.* 1989). The leading exponent for Strassen's algorithm for a POWER of 2 is $\lg 7 \approx 2.808$. The best leading exponent currently known is 2.376 (Coppersmith and Winograd 1990). It has been shown that the exponent must be at least 2.

Strassman's Theorem

Let $(K, |\cdot|)$ be a complete non-ARCHIMEDEAN VALUATED FIELD, with VALUATION RING R, and let $f(X)$ be a POWER series with COEFFICIENTS in R. Suppose at least one of the COEFFICIENTS is NONZERO (so that f is not identically zero) and the sequence of COEFFICIENTS converges to 0 with respect to $|\cdot|$. Then $f(X)$ has only finitely many zeros in R.

Strehl Identity

The sum identity

$$\sum_{j=0}^{\infty} \binom{n}{j}^3 = \sum_{k=0}^{\infty} \binom{n}{k}^2 \binom{2(n-k)}{n},$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

see also BINOMIAL COEFFICIENT

Striction Curve

A NONCYLINDRICAL RULED SURFACE always has a parameterization of the form

$$\mathbf{x}(u,v) = \boldsymbol{\sigma}(u) + v\boldsymbol{\delta}(u), \tag{1}$$

where $|\boldsymbol{\delta}| = 1$, $\boldsymbol{\sigma}' \cdot \boldsymbol{\delta}' = 0$, and $\boldsymbol{\sigma}$ is called the striction curve of $\mathbf{x}$. Furthermore, the striction curve does not depend on the choice of the base curve. The striction and DIRECTOR CURVES of the HELICOID

$$\mathbf{x}(u,v) = \begin{bmatrix} 0 \\ 0 \\ bu \end{bmatrix} + av \begin{bmatrix} \cos u \\ \sin u \\ 0 \end{bmatrix} \tag{2}$$

are

$$\boldsymbol{\sigma}(u) = \begin{bmatrix} 0 \\ 0 \\ bu \end{bmatrix} \tag{3}$$

$$\boldsymbol{\delta}(u) = \begin{bmatrix} a\cos u \\ a\sin u \\ 0 \end{bmatrix}. \tag{4}$$

For the HYPERBOLIC PARABOLOID

$$\mathbf{x}(u,v) = \begin{bmatrix} u \\ 0 \\ 0 \end{bmatrix} + v \begin{bmatrix} 0 \\ 1 \\ u \end{bmatrix}, \tag{5}$$

the striction and DIRECTOR CURVES are

$$\boldsymbol{\sigma}(u) = \begin{bmatrix} u \\ 0 \\ 0 \end{bmatrix} \tag{6}$$

$$\boldsymbol{\delta}(u) = \begin{bmatrix} 0 \\ 1 \\ u \end{bmatrix}. \tag{7}$$

Strip

see CRITICAL STRIP, MÖBIUS STRIP

Strong Convergence

Strong convergence is the type of convergence usually associated with convergence of a SEQUENCE. More formally, a SEQUENCE $\{x_n\}$ of VECTORS in an INNER PRODUCT SPACE E is called convergent to a VECTOR x in E if

$$\|x_n - x\| \to 0 \quad \text{as } n \to \infty.$$

see also CONVERGENT SEQUENCE, INNER PRODUCT SPACE, WEAK CONVERGENCE

Strong Elliptic Pseudoprime

Let n be an ELLIPTIC PSEUDOPRIME associated with (E, P), and let $n+1 = 2^s k$ with k ODD and $s \geq 0$. Then n is a strong elliptic pseudoprime when either $kP \equiv 0 \pmod{n}$ or $2^r kP \equiv 0 \pmod{n}$ for some r with $1 \leq r < s$.

see also ELLIPTIC PSEUDOPRIME

Strong Frobenius Pseudoprime

A PSEUDOPRIME which obeys an additional restriction beyond that required for a FROBENIUS PSEUDOPRIME. A number n with $(n, 2a) = 1$ is a strong Frobenius pseudoprime with respect to $x - a$ IFF n is a STRONG PSEUDOPRIME with respect to $f(x)$. Every strong Frobenius pseudoprime with respect to $x - a$ is an EULER PSEUDOPRIME to the base a.

Every strong Frobenius pseudoprime with respect to $f(x) = x^2 - bx - c$ such that $((b^2 + 4c)/n) = -1$ is a STRONG LUCAS PSEUDOPRIME with parameters (b, c). Every strong Frobenius pseudoprime n with respect to $x^2 - bx + 1$ is an EXTRA STRONG LUCAS PSEUDOPRIME to the base b.

see also FROBENIUS PSEUDOPRIME

Strong Lucas Pseudoprime

Let $U(P, Q)$ and $V(P, Q)$ be LUCAS SEQUENCES generated by P and Q, and define

$$D \equiv P^2 - 4Q.$$

Let n be an ODD COMPOSITE NUMBER with $(n, D) = 1$, and $n - (D/n) = 2^s d$ with d ODD and $s \geq 0$, where (a/b) is the LEGENDRE SYMBOL. If

$$U_d \equiv 0 \pmod{n}$$

or

$$V_{2^r d} \equiv 0 \pmod{n}$$

for some r with $0 \leq r < s$, then n is called a strong Lucas pseudoprime with parameters (P, Q).

A strong Lucas pseudoprime is a LUCAS PSEUDOPRIME to the same base. Arnault (1997) showed that any COMPOSITE NUMBER n is a strong Lucas pseudoprime for at most 4/15 of possible bases (unless n is the PRODUCT of TWIN PRIMES having certain properties).

see also EXTRA STRONG LUCAS PSEUDOPRIME, LUCAS PSEUDOPRIME

Strong Pseudoprime

A strong pseudoprime to a base a is an ODD COMPOSITE NUMBER n with $n - 1 = d \cdot 2^s$ (for d ODD) for which either

$$a^d \equiv 1 \pmod{n} \tag{1}$$

or

$$a^{d \cdot 2^r} \equiv -1 \pmod{n} \tag{2}$$

for some $r \in [0, s)$.

The definition is motivated by the fact that a FERMAT PSEUDOPRIME n to the base b satisfies

$$b^{n-1} - 1 \equiv 0 \pmod{n}. \tag{3}$$

But since n is ODD, it can be written $n = 2m + 1$, and

$$b^{2m} - 1 = (b^m - 1)(b^m + 1) \equiv 0 \pmod{n}. \tag{4}$$

If n is PRIME, it must DIVIDE at least one of the FACTORS, but can't DIVIDE both because it would then DIVIDE their difference

$$(b^m + 1) - (b^m - 1) = 2. \tag{5}$$

Therefore,

$$b^m \equiv \pm 1 \pmod{n}, \tag{6}$$

so write $n = 2^a t + 1$ to obtain

$$b^{n-1} - 1 = (b^t - 1)(b^t + 1)(b^{2t} + 1) \cdots (b^{2^{a-1}t} + 1). \tag{7}$$

If n DIVIDES exactly one of these FACTORS but is COMPOSITE, it is a strong pseudoprime. A COMPOSITE number is a strong pseudoprime to at most 1/4 of all bases less than itself (Monier 1980, Rabin 1980). The strong pseudoprimes provide the basis for MILLER'S PRIMALITY TEST and RABIN-MILLER STRONG PSEUDOPRIME TEST.

A strong pseudoprime to the base a is also an EULER PSEUDOPRIME to the base a (Pomerance *et al.* 1980). The strong pseudoprimes include some EULER PSEUDOPRIMES, FERMAT PSEUDOPRIMES, and CARMICHAEL NUMBERS.

There are 4842 strong psp(2) less than 2.5×10^{10}, where a psp(2) is also known as a POULET NUMBER. The strong k-pseudoprime test for $k = 2, 3, 5$ correctly identifies all PRIMES below 2.5×10^{10} with only 13 exceptions, and if 7 is added, then the only exception less than 2.5×10^{10} is 315031751. Jaeschke (1993) showed that there are only 101 strong pseudoprimes for the bases 2, 3, and 5 less than 10^{12}, nine if 7 is added, and none if 11 is added. Also, the bases 2, 13, 23, and 1662803 have no exceptions up to 10^{12}.

If n is COMPOSITE, then there is a base for which n is not a strong pseudoprime. There are therefore no "strong CARMICHAEL NUMBERS." Let ψ_k denote the smallest strong pseudoprime to all of the first k PRIMES taken as bases (i.e, the smallest ODD NUMBER for which the RABIN-MILLER STRONG PSEUDOPRIME TEST on bases less than or equal to k fails). Jaeschke (1993) computed ψ_k from $k = 5$ to 8 and gave upper bounds for $k = 9$ to 11.

$$\begin{aligned}
\psi_1 &= 2047\\
\psi_2 &= 1373653\\
\psi_3 &= 25326001\\
\psi_4 &= 3215031751\\
\psi_5 &= 2152302898747\\
\psi_6 &= 3474749660383\\
\psi_7 &= 34155071728321\\
\psi_8 &= 34155071728321\\
\psi_9 &\leq 41234316135705689041\\
\psi_{10} &\leq 1553360566073143205541002401\\
\psi_{11} &\leq 56897193526942024370326972321
\end{aligned}$$

(Sloane's A014233). A seven-step test utilizing these results (Riesel 1994) allows all numbers less than 3.4×10^{14} to be tested.

Pomerance *et al.* (1980) have proposed a test based on a combination of STRONG PSEUDOPRIMES and LUCAS PSEUDOPRIMES. They offer a \$620 reward for discovery of a COMPOSITE NUMBER which passes their test (Guy 1994, p. 28).

Strophoid

Let C be a curve, let O be a fixed point (the POLE), and let O' be a second fixed point. Let P and P' be points on a line through O meeting C at Q such that $P'Q = QP = QO'$. The LOCUS of P and P' is called the strophoid of C with respect to the POLE O and fixed point O'. Let C be represented parametrically by $(f(t), g(t))$, and let $O = (x_0, y_0)$ and $O' = (x_1, y_1)$. Then the equation of the strophoid is

$$x = f \pm \sqrt{\frac{(x_1 - f)^2 + (y_1 - g)^2}{1 + m^2}} \quad (1)$$

$$y = g \pm \sqrt{\frac{(x_1 - f)^2 + (y_1 - g)^2}{1 + m^2}}, \quad (2)$$

where

$$m \equiv \frac{g - y_0}{f - x_0}. \quad (3)$$

The name strophoid means "belt with a twist," and was proposed by Montucci in 1846 (MacTutor Archive). The polar form for a general strophoid is

$$r = \frac{b \sin(a - 2\theta)}{\sin(a - \theta)}. \quad (4)$$

If $a = \pi/2$, the curve is a RIGHT STROPHOID. The following table gives the strophoids of some common curves.

Curve	Pole	Fixed Point	Strophoid
line	not on line	on line	oblique strophoid
line	not on line	foot of ⊥ origin to line	right strophoid
circle	center	on circumf.	Freeth's nephroid

see also RIGHT STROPHOID

Structurally Stable

A MAP $\phi : M \to M$ where M is a MANIFOLD is C^r structurally stable if any C^r perturbation is TOPOLOGICALLY CONJUGATE to ϕ. Here, C^r perturbation means a FUNCTION ψ such that ψ is close to ϕ and the first r derivatives of ψ are close to those of ϕ.

see also TOPOLOGICALLY CONJUGATE

Structure

see LATTICE

Structure Constant

The structure constant is defined as $i\epsilon_{ijk}$, where ϵ_{ijk} is the PERMUTATION SYMBOL. The structure constant forms the starting point for the development of LIE ALGEBRA.

see also LIE ALGEBRA, PERMUTATION SYMBOL

Structure Factor

The structure factor S_Γ of a discrete set Γ is the FOURIER TRANSFORM of δ-scatterers of equal strengths on all points of Γ,

$$S_\Gamma(k) = \int \sum_{x \in \Gamma} \delta(x' - x) e^{-2\pi i k x'}\, dx' = \sum_{x \in \Gamma} e^{-2\pi i k x}.$$

Struve Differential Equation

The ordinary differential equation

$$z^2 y'' + z y' + (z^2 - \nu^2) y = \frac{4(\frac{1}{2}z)^{\nu+1}}{\sqrt{\pi}\,\Gamma(\nu + \frac{1}{2})},$$

where $\Gamma(z)$ is the GAMMA FUNCTION. The solution is

$$y = a J_\nu(z) + b Y_\nu(z) + \mathcal{H}_\nu(z),$$

where $J_\nu(z)$ and $Y_\nu(z)$ are BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS, and $\mathcal{H}_\nu(z)$ is a STRUVE FUNCTION (Abramowitz and Stegun 1972).

see also Bessel Function of the First Kind, Bessel Function of the Second Kind, Struve Function

References

Abramowitz, M. and Stegun, C. A. (Eds.). *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, 9th printing.* New York: Dover, pp. 496, 1972.

Struve Function

Abramowitz and Stegun (1972, pp. 496–499) define the Struve function as

$$\mathcal{H}_\nu(z) = (\tfrac{1}{2}z)^{\nu+1} \sum_{k=0}^{\infty} \frac{(-1)^k (\frac{1}{2}z)^{2k}}{\Gamma(k+\frac{3}{2})\Gamma(k+\nu+\frac{3}{2})}, \qquad (1)$$

where $\Gamma(z)$ is the Gamma Function. Watson (1966, p. 338) defines the Struve function as

$$\mathcal{H}_\nu(z) \equiv \frac{2(\frac{1}{2}z)^\nu}{\Gamma(\nu+\frac{1}{2})\Gamma(\frac{1}{2})} \int_0^1 (1-t^2)^{\nu-1/2} \sin(zt)\,dt. \quad (2)$$

The series expansion is

$$\mathcal{H}_\nu(z) = \sum_{m=0}^{\infty} (-1)^m \frac{(\frac{1}{2}z)^{2m+\nu+1}}{\Gamma(m+\frac{3}{2})\Gamma(\nu+m+\frac{3}{2})}. \qquad (3)$$

For half integral orders,

$$\begin{aligned} &\mathcal{H}_{n+1/2}(z) \\ &\quad = Y_{n+1/2}(z) + \frac{1}{\pi} \sum_{m=0}^{n} \frac{\Gamma(m+\frac{1}{2})(\frac{1}{2}z)^{-2m+n-1/2}}{\Gamma(n+1-m)} &(4) \\ &\mathcal{H}_{-(n+1/2)}(z) = (-1)^n J_{n+1/2}(z). &(5) \end{aligned}$$

The Struve function and its derivatives satisfy

$$\mathcal{H}_{\nu-1}(z) - \mathcal{H}_{\nu+1}(z) = 2\mathcal{H}'_\nu(z) - \frac{(\frac{1}{2}z)^\nu}{\sqrt{\pi}\,\Gamma(\nu+\frac{3}{2})}. \qquad (6)$$

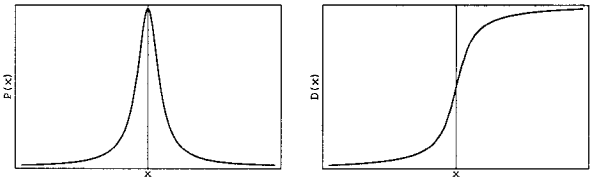
Student's *t*-Distribution



A Distribution published by William Gosset in 1908. His employer, Guinness Breweries, required him to publish under a pseudonym, so he chose "Student." Given n independent measurements x_i, let

$$t \equiv \frac{\bar{x}-\mu}{s/\sqrt{n}}, \qquad (1)$$

where μ is the population Mean, $\bar{x}$ is the sample Mean, and s is the Estimator for population Standard Deviation (i.e., the Sample Variance) defined by

$$s^2 \equiv \frac{1}{N-1} \sum_{i=1}^{n} (x_i - \bar{x})^2. \qquad (2)$$

Student's t-distribution is defined as the distribution of the random variable t which is (very loosely) the "best" that we can do not knowing σ. If $\sigma = s$, $t = z$ and the distribution becomes the Normal Distribution. As N increases, Student's t-distribution approaches the Normal Distribution.

Student's t-distribution is arrived at by transforming to Student's z-Distribution with

$$z \equiv \frac{\bar{x}-\mu}{s}. \qquad (3)$$

Then define

$$t \equiv z\sqrt{n-1}. \qquad (4)$$

The resulting probability and cumulative distribution functions are

$$\begin{aligned} f_r(t) &= \frac{\Gamma\left(\frac{r+1}{2}\right)}{\sqrt{r\pi}\,\Gamma\left(\frac{r}{2}\right)\left(1+\frac{t^2}{r}\right)^{(r+1)/2}} \\ &= \frac{\left(\frac{r}{r+t^2}\right)^{(1+r)/2}}{\sqrt{r}\,B(\frac{1}{2}r,\frac{1}{2})} &(5) \\ F_r(t) &= \int_{-\infty}^{t} \frac{\Gamma\left(\frac{r+1}{2}\right)}{\sqrt{r\pi}\,\Gamma\left(\frac{r}{2}\right)\left(1+\frac{t^2}{r}\right)^{(r+1)/2}}\,dt \\ &= \frac{1}{\sqrt{n}B\left(\frac{r}{2},\frac{1}{2}\right)\left(1+\frac{t^2}{r}\right)^{(r+1)/2}} \\ &= \frac{1}{2} + \frac{1}{2}\left[I(1;\tfrac{1}{2}n,\tfrac{1}{2}) - I\left(\frac{r}{r+t^2},\tfrac{1}{2}n,\tfrac{1}{2}\right)\right], \\ & &(6) \end{aligned}$$

where

$$r \equiv n-1 \qquad (7)$$

is the number of Degrees of Freedom, $-\infty < t < \infty$, $\Gamma(z)$ is the Gamma Function, $B(a,b)$ is the Beta Function, and $I(z;a,b)$ is the Regularized Beta Function defined by

$$I(z;a,b) = \frac{B(z;a,b)}{B(a,b)}. \tag{8}$$

The Mean, Variance, Skewness, and Kurtosis of Student's t-distribution are

$$\mu = 0 \tag{9}$$

$$\sigma^2 = \frac{r}{r-2} \tag{10}$$

$$\gamma_1 = 0 \tag{11}$$

$$\gamma_2 = \frac{6}{r-4}. \tag{12}$$

Beyer (1987, p. 514) gives 60%, 70%, 90%, 95%, 97.5%, 99%, 99.5%, and 99.95% confidence intervals, and Goulden (1956) gives 50%, 90%, 95%, 98%, 99%, and 99.9% confidence intervals. A partial table is given below for small r and several common confidence intervals.

r	80%	90%	95%	99%
1	3.08	6.31	12.71	63.66
2	1.89	2.92	4.30	9.92
3	1.64	2.35	3.18	5.84
4	1.53	2.13	2.78	4.60
5	1.48	2.01	2.57	4.03
10	1.37	1.81	2.23	4.14
30	1.31	1.70	2.04	2.75
100	1.29	1.66	1.98	2.63
∞	1.28	1.65	1.96	2.58

The so-called $A(t|n)$ distribution is useful for testing if two observed distributions have the same Mean. $A(t|n)$ gives the probability that the difference in two observed Means for a certain statistic t with n Degrees of Freedom would be smaller than the observed value purely by chance:

$$A(t|n) = \frac{1}{\sqrt{n}\,B(\tfrac{1}{2},\tfrac{1}{2}n)} \int_{-t}^{t} \left(1+\frac{x^2}{n}\right)^{-(1+n)/2} dx. \tag{13}$$

Let X be a Normally Distributed random variable with Mean 0 and Variance σ^2, let Y^2/σ^2 have a Chi-Squared Distribution with n Degrees of Freedom, and let X and Y be independent. Then

$$t \equiv \frac{X\sqrt{n}}{Y} \tag{14}$$

is distributed as Student's t with n Degrees of Freedom.

The noncentral Student's t-distribution is given by

$$\begin{aligned} P(x) = {} & \frac{n^{n/2}n!}{2^n e^{\lambda^2/2}\Gamma(\frac{1}{2}n)} \\ & \times \left\{ \frac{\sqrt{2}\,\lambda x(n+x^2)^{-(1+n/2)}\,{}_1F_1\left(1+\frac{1}{2}n;\frac{3}{2};\frac{\lambda^2x^2}{2(n+x^2)}\right)}{\Gamma[\frac{1}{2}(1+n)]} \right. \\ & \left. \frac{+e^{(\lambda^2x^2)/[2(n+x^2)]}\sqrt{\pi}(n+x^2)^{-(n+1)/2}L_{n/2}^{-1/2}\left(-\frac{\lambda^2x^2}{2(n+x^2)}\right)}{\Gamma[\frac{1}{2}(1+n)]} \right\}, \end{aligned} \tag{15}$$

where $\Gamma(z)$ is the Gamma Function, ${}_1F_1(a;b;z)$ is a Confluent Hypergeometric Function, and $L_n^m(x)$ is an associated Laguerre Polynomial.

Student's z-Distribution

The probability density function and cumulative distribution functions for Student's z-distribution are given by

$$f(z) = \frac{\Gamma\left(\frac{n}{2}\right)}{\sqrt{\pi}\,\Gamma\left(\frac{n-1}{2}\right)}(1+z^2)^{-n/2} \tag{1}$$

$$D(z) = \frac{-z^{1-n}\Gamma(\frac{1}{2}n)\,{}_2F_1(\frac{1}{2}(n-1),\frac{1}{2}n;\frac{1}{2}(n+1);-z^{-2})}{2\sqrt{\pi}\,\Gamma[\frac{1}{2}(n+1)]}. \tag{2}$$

The Mean is 0, so the Moments are

$$\mu_1 = 0 \tag{3}$$

$$\mu_2 = \frac{1}{n-3} \tag{4}$$

$$\mu_3 = 0 \tag{5}$$

$$\mu_4 = \frac{3}{(n-3)(n-5)}. \tag{6}$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = 0 \tag{7}$$

$$\sigma^2 = \frac{1}{n-3} \tag{8}$$

$$\gamma_1 = 0 \tag{9}$$

$$\gamma_2 = \frac{6}{n-5}. \tag{10}$$

Letting

$$z \equiv \frac{(\bar{x}-\mu)}{s}, \tag{11}$$

where x is the sample MEAN and μ is the population MEAN gives STUDENT'S t-DISTRIBUTION.

see also STUDENT'S t-DISTRIBUTION

Study's Theorem

Given three curves ϕ_1, ϕ_2, ϕ_3 with the common group of ordinary points G (which may be empty), let their remaining groups of intersections g_{23}, g_{31}, and g_{12} also be ordinary points. If ϕ_1' is any other curve through g_{23}, then there exist two other curves ϕ_2', ϕ_3' such that the three combined curves $\phi_i\phi_i'$ are of the same order and LINEARLY DEPENDENT, each curve ϕ_k' contains the corresponding group g_{ij}, and every intersection of ϕ_i or ϕ_i' with ϕ_j or ϕ_j' lies on ϕ_k or ϕ_k'.

Sturm Chain

The series of STURM FUNCTIONS arising in application of the STURM THEOREM.

see also STURM FUNCTION, STURM THEOREM

Sturm Function

Given a function $f(x) \equiv f_0(x)$, write $f_1 \equiv f'(x)$ and define the Sturm functions by

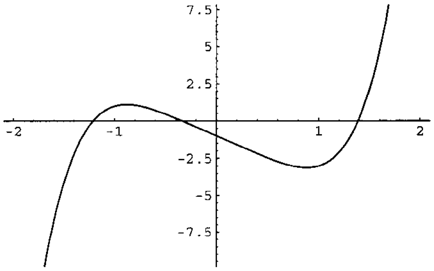
$$f_n(x) = -\left\{ f_{n-2}(x) - f_{n-1}(x)\left[\frac{f_{n-2}(x)}{f_{n-1}(x)}\right]\right\}, \tag{1}$$

where $[P(x)/Q(x)]$ is a polynomial quotient. Then construct the following chain of Sturm functions,

$$\begin{aligned} f_0 &= q_0 f_1 - f_2 \\ f_1 &= q_1 f_2 - f_3 \\ f_2 &= q_2 f_3 - f_4 \\ &\vdots \\ f_{s-2} &= q_{s-2} f_{s-1} - f_s, \end{aligned} \tag{2}$$

known as a STURM CHAIN. The chain is terminated when a constant $-f_s(x)$ is obtained.

Sturm functions provide a convenient way for finding the number of real roots of an algebraic equation with real coefficients over a given interval. Specifically, the difference in the number of sign changes between the Sturm functions evaluated at two points $x = a$ and $x = b$ gives the number of real roots in the interval (a, b). This powerful result is known as the STURM THEOREM.



As a specific application of Sturm functions toward finding POLYNOMIAL ROOTS, consider the function $f_0(x) = x^5 - 3x - 1$, plotted above, which has roots -1.21465, -0.334734, $0.0802951 \pm 1.32836i$, and 1.38879 (three of which are real). The DERIVATIVE is given by $f'(x) = 5x^4 - 3$, and the STURM CHAIN is then given by

$$f_0 = x^5 - 3x - 1 \tag{3}$$

$$f_1 = 5x^4 - 3 \tag{4}$$

$$f_2 = \tfrac{1}{5}(12x + 5) \tag{5}$$

$$f_3 = \tfrac{59083}{20736}. \tag{6}$$

The following table shows the signs of f_i and the number of sign changes Δ obtained for points separated by $\Delta x = 2$.

x	f_0	f_1	f_2	f_3	Δ
-2	-1	1	-1	1	3
0	-1	-1	1	1	1
2	1	1	1	1	0

This shows that $3 - 1 = 2$ real roots lie in $(-2, 0)$, and $1 - 0 = 1$ real root lies in $(0, 2)$. Reducing the spacing to $\Delta x = 0.5$ gives the following table.

x	f_0	f_1	f_2	f_3	Δ
-2.0	-1	1	-1	1	3
-1.5	-1	1	-1	1	3
-1.0	1	1	-1	1	2
-0.5	1	-1	-1	1	2
0.0	-1	-1	1	1	1
0.5	-1	-1	1	1	1
1.0	-1	1	1	1	1
1.5	1	1	1	1	0
2.0	1	1	1	1	0

This table isolates the three real roots and shows that they lie in the intervals $(-1.5, -1.0)$, $(-0.5, 0.0)$, and $(1.0, 1.5)$. If desired, the intervals in which the roots fall could be further reduced.

The Sturm functions satisfy the following conditions:

1. Two neighboring functions do not vanish simultaneously at any point in the interval.
2. At a null point of a Sturm function, its two neighboring functions are of different signs.
3. Within a sufficiently small AREA surrounding a zero point of $f_0(x)$, $f_1(x)$ is everywhere greater than zero or everywhere smaller than zero.

Sturm-Liouville Equation

A second-order ORDINARY DIFFERENTIAL EQUATION

$$\frac{d}{dx}\left[p(x)\frac{dy}{dx}\right]+[\lambda w(x)-q(x)]y=0,$$

where λ is a constant and $w(x)$ is a known function called either the density or WEIGHTING FUNCTION. The solutions (with appropriate boundary conditions) of λ are called EIGENVALUES and the corresponding $u_\lambda(x)$ EIGENFUNCTIONS. The solutions of this equation satisfy important mathematical properties under appropriate boundary conditions (Arfken 1985).

Sturm-Liouville Theory

see STURM-LIOUVILLE EQUATION

Sturm Theorem

The number of REAL ROOTS of an algebraic equation with REAL COEFFICIENTS whose REAL ROOTS are simple over an interval, the endpoints of which are not ROOTS, is equal to the difference between the number of sign changes of the STURM CHAINS formed for the interval ends.

see also STURM CHAIN, STURM FUNCTION

Sturmian Separation Theorem

Let $\mathsf{A}_r = a_{ij}$ be a SEQUENCE of N SYMMETRIC MATRICES of increasing order with $i, j = 1, 2, \ldots, r$ and $r = 1, 2, \ldots, N$. Let $\lambda_k(\mathsf{A}_r)$ be the kth EIGENVALUE of A_r for $k = 1, 2, \ldots, r$, where the ordering is given by

$$\lambda_1(\mathsf{A}_r)\geq\lambda_2(\mathsf{A}_r)\geq\ldots\geq\lambda_r(\mathsf{A}_r).$$

Then it follows that

$$\lambda_{k+1}(\mathsf{A}_{i+1})\leq\lambda_k(\mathsf{A}_i)\leq\lambda_k(\mathsf{A}_{i+1}).$$

Sturmian Sequence

If a SEQUENCE has the property that the BLOCK GROWTH function $B(n) = n + 1$ for all n, then it is said to have minimal block growth, and the sequence is called a Sturmian sequence. An example of this is the sequence arising from the SUBSTITUTION MAP

$$\begin{aligned}0&\to 01\\ 1&\to 0,\end{aligned}$$

yielding $0 \to 01 \to 010 \to 01001 \to 01001010 \to \ldots$, which gives us the Sturmian sequence 01001010....

STURM FUNCTIONS are sometimes also said to form a Sturmian sequence.

see also STURM FUNCTION, STURM THEOREM

Subalgebra

An ALGEBRA S' which is part of a large ALGEBRA S and shares its properties.

see also ALGEBRA

Subanalytic

$X \subseteq \mathbb{R}^n$ is subanalytic if, for all $x \in \mathbb{R}^n$, there is an open U and $Y \subset \mathbb{R}^{n+m}$ a bounded SEMIANALYTIC set such that $X \cap U$ is the projection of Y into U.

see also SEMIANALYTIC

References
Bierstone, E. and Milman, P. "Semialgebraic and Subanalytic Sets." *IHES Pub. Math.* **67**, 5–42, 1988.

Subfactorial

The number of Permutations of n objects in which no object appear in its natural place (i.e., so-called "Derangements").

$$!n \equiv n! \sum_{k=0}^{n} \frac{(-1)^k}{k!} \tag{1}$$

or

$$!n \equiv \left[\frac{n!}{e}\right], \tag{2}$$

where $k!$ is the usual Factorial and $[x]$ is the Nint function. The first few values are $!1 = 0$, $!2 = 1$, $!3 = 2$, $!4 = 9$, $!5 = 44$, $!6 = 265$, $!7 = 1854$, $!8 = 14833$, ... (Sloane's A000166). For example, the only Derangements of $\{1,2,3\}$ are $\{2,3,1\}$ and $\{3,1,2\}$, so $!3 = 2$. Similarly, the Derangements of $\{1,2,3,4\}$ are $\{2,1,4,3\}$, $\{2,3,4,1\}$, $\{2,4,1,3\}$, $\{3,1,4,2\}$, $\{3,4,1,2\}$, $\{3,4,2,1\}$, $\{4,1,2,3\}$, $\{4,3,1,2\}$, and $\{4,3,2,1\}$, so $!4 = 9$.

The subfactorials are also called the Rencontres Numbers and satisfy the Recurrence Relations

$$!n = n{\cdot}!(n-1) + (-1)^n \tag{3}$$

$$!(n+1) = n[!n+!(n-1)]. \tag{4}$$

The subfactorial can be considered a special case of a restricted Rooks Problem.

The only number equal to the sum of subfactorials of its digits is

$$148,349 = !1+!4+!8+!3+!4+!9 \tag{5}$$

(Madachy 1979).

Subfield

If a subset S of the elements of a Field F satisfies the Field Axioms with the same operations of F, then S is called a subfield of F. Let F be a Finite Field of order p^n, then there exists a subfield of Order p^m for Prime p Iff m Divides n.

see also Field, Submanifold, Subspace

Subgraph

A Graph G' whose Vertices and Edges form subsets of the Vertices and Edges of a given Graph G. If G' is a subgraph of G, then G is said to be a Supergraph of G'.

see also Graph (Graph Theory), Supergraph

Subgroup

A subset of Group elements which satisfies the four Group requirements. The Order of any subgroup of a Group Order h must be a Divisor of h.

see also Cartan Subgroup, Composition Series, Fitting Subgroup, Group

Sublime Number

Let $\tau(n)$ and $\sigma(n)$ denote the number and sum of the divisors of n, respectively (i.e., the zeroth- and first-order Divisor Functions). A number N is called sublime if $\tau(N)$ and $\sigma(N)$ are both Perfect Numbers. The only two known sublime numbers are 12 and

$$60865556702383789896703717342431696\cdots$$
$$\cdots 22657830773351885970528324860512791691264.$$

It is not known if any Odd sublime number exists.

see also Divisor Function, Perfect Number

Submanifold

A C^∞ (infinitely differentiable) Manifold is said to be a submanifold of a C^∞ Manifold M' if M is a Subset of M' and the Identity Map of M into M' is an embedding.

see also Manifold, Subfield, Subspace

Submatrix

An $p \times q$ submatrix of an $m \times n$ Matrix (with $p \leq m$, $n \leq q$) is a $p \times q$ Matrix formed by taking a block of the entries of this size from the original matrix.

see also Matrix

Subnormal

L is a subnormal Subgroup of H if there is a a "normal series" (in the sense of Jordan-Holder) from L to H.

Subordinate Norm

see Natural Norm

Subscript

A quantity displayed below the normal line of text (and generally in a smaller point size), as the "i" in a_i, is called a subscript. Subscripts are commonly used to indicate indices (a_{ij} is the entry in the ith row and jth column of a Matrix A), partial differentiation (y_x is an abbreviation for $\partial y/\partial x$), and a host of other operations and notations in mathematics.

see also Superscript

Subsequence

A subsequence of a SEQUENCE $S = \{x_i\}_{i=1}^{n}$ is a derived sequence $\{y_i\}_{i=1}^{N} = \{x_{i+j}\}$ for some $j \geq 0$ and $N \leq n - j$. More generally, the word subsequence is sometimes used to mean a sequence derived from a sequence S by discarding some of its terms.

see also LOWER-TRIMMED SUBSEQUENCE, UPPER-TRIMMED SUBSEQUENCE

Subset

A portion of a SET. B is a subset of A (written $B \subseteq A$) IFF every member of B is a member of A. If B is a PROPER SUBSET of A (i.e., a subset other than the set itself), this is written $B \subset A$.

A SET of n elements has 2^n subsets (including the set itself and the EMPTY SET). For sets of $n = 1, 2, \ldots$ elements, the numbers of subsets are therefore 2, 4, 8, 16, 32, 64, ... (Sloane's A000079). For example, the set $\{1\}$ has the two subsets $\varnothing$ and $\{1\}$. Similarly, the set $\{1, 2\}$ has subsets $\varnothing$ (the EMPTY SET, $\{1\}$, $\{2\}$, and $\{1, 2\}$.

see also EMPTY SET, IMPLIES, k-SUBSET, PROPER SUBSET, SUPERSET, VENN DIAGRAM

References

Sloane, N. J. A. Sequence A000079/M1129 in "An On-Line Version of the Encyclopedia of Integer Sequences."

Subspace

Let $\mathbb{V}$ be a REAL VECTOR SPACE (e.g., the real continuous functions $C(I)$ on a CLOSED INTERVAL I, 2-D EUCLIDEAN SPACE $\mathbb{R}^2$, the twice differentiable real functions $C^{(2)}(I)$ on I, etc.). Then $\mathbb{W}$ is a real SUBSPACE of $\mathbb{V}$ if $\mathbb{W}$ is a SUBSET of $\mathbb{V}$ and, for every $\mathbf{w}_1, \mathbf{w}_2 \in \mathbb{W}$ and $t \in \mathbb{R}$ (the REALS), $\mathbf{w}_1 + \mathbf{w}_2 \in \mathbb{W}$ and $t\mathbf{w}_1 \in \mathbb{W}$. Let (H) be a homogeneous system of linear equations in $x_1, \ldots, x_n$. Then the SUBSET S of $\mathbb{R}^n$ which consists of all solutions of the system (H) is a subspace of $\mathbb{R}^n$.

More generally, let F_q be a FIELD with $q = p^\alpha$, where p is PRIME, and let $F_{q,n}$ denote the n-D VECTOR SPACE over F_q. The number of k-D linear subspaces of $F_{q,n}$ is

$$N(F_{q,n}) = \binom{n}{k}_q,$$

where this is the q-BINOMIAL COEFFICIENT (Aigner 1979, Exton 1983). The asymptotic limit is

$$N(F_{q,n}) = \begin{cases} c_e q^{n^2/4}[1 + o(1)] & \text{for } n \text{ even} \\ c_o q^{n^2/4}[1 + o(1)] & \text{for } n \text{ odd,} \end{cases}$$

where

$$c_e = \frac{\sum_{k=-\infty}^{\infty} q^{-k^2}}{\prod_{j=1}^{\infty}(1 - q^{-j})}$$

$$c_o = \frac{\sum_{k=-\infty}^{\infty} q^{-(k+1/2)^2}}{\prod_{j=1}^{\infty}(1 - q^{-j})}$$

(Finch). The case $q = 2$ gives the q-ANALOG of the WALLIS FORMULA.

see also q-BINOMIAL COEFFICIENT, SUBFIELD, SUBMANIFOLD

Finch, S. "Favorite Mathematical Constants." `http://www.mathsoft.com/asolve/constant/dig/dig.html`.

Substitution Group

see PERMUTATION GROUP

Substitution Map

A MAP which uses a set of rules to transform elements of a sequence into a new sequence using a set of rules which "translate" from the original sequence to its transformation. For example, the substitution map $\{1 \to 0, 0 \to 11\}$ would take 10 to 011.

see also GOLDEN RATIO, MORSE-THUE SEQUENCE, STRING REWRITING, THUE CONSTANT

Subtend

Given a geometric object O in the PLANE and a point P, let A be the ANGLE from one edge of O to the other with VERTEX at P. Then O is said to subtend an ANGLE A from P.

see also ANGLE, VERTEX ANGLE

Subtraction

Subtraction is the operation of taking the DIFFERENCE $x - y$ of two numbers x and y. Here, the symbol between the x and y is called the MINUS SIGN and $x - y$ is read "x MINUS y."

see also ADDITION, DIVISION, MINUS, MINUS SIGN, MULTIPLICATION

Succeeds

The relationship x succeeds (or FOLLOWS) y is written $x \succ y$. The relation x succeeds or is equal to y is written $x \succeq y$.

see also PRECEDES

Successes

see DIFFERENCE OF SUCCESSES

Sufficient

A CONDITION which, if true, guarantees that a result is also true. (However, the result may also be true if the CONDITION is not met.) If a CONDITION is both NECESSARY and SUFFICIENT, then the result is said to be true IFF ("if and only if") the CONDITION holds.

For example, the condition that a decimal number n end in the DIGIT 2 is a sufficient but not NECESSARY condition that n be EVEN.

see also IFF, IMPLIES, NECESSARY

Suitable Number

see IDONEAL NUMBER

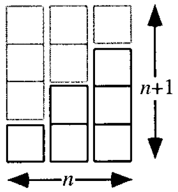
Sum

A sum is the result of an ADDITION. For example, adding 1, 2, 3, and 4 gives the sum 10, written

$$1+2+3+4=10. \tag{1}$$

The numbers being summed are called ADDENDS, or sometimes SUMMANDS. The summation operation can also be indicated using a capital sigma with upper and lower limits written above and below, and the index indicated below. For example, the above sum could be written

$$\sum_{k=1}^{4} k = 10. \tag{2}$$



A simple graphical proof of the sum $\sum_{k=1}^{n} k = n(n+1)/2$ can also be given. Construct a sequence of stacks of boxes, each 1 unit across and k units high, where $k = 1$, 2, ..., n. Now add a rotated copy on top, as in the above figure. Note that the resulting figure has WIDTH n and HEIGHT $n+1$, and so has AREA $n(n+1)$. The desired sum is half this, so the AREA of the boxes in the sum is $n(n+1)/2$. Since the boxes are of unit width, this is also the value of the sum.

The sum can also be computed using the first EULER-MACLAURIN INTEGRATION FORMULA

$$\sum_{k=1}^{n} f(k) = \int_1^n f(x)\,dx + \tfrac{1}{2}f(1) + \tfrac{1}{2}f(n) + \tfrac{1}{2!}B_2[f'(n) - f'(1)] + \ldots \tag{3}$$

with $f(k) = k$. Then

$$\sum_{k=1}^{n} k = \int_1^n x\,dx + \tfrac{1}{2}\cdot 1 + \tfrac{1}{2}\cdot n + \tfrac{1}{6}(1-1) + \ldots = \tfrac{1}{2}(n^2-1) - \tfrac{1}{2} + h + \tfrac{1}{2}n = \tfrac{1}{2}n(n+1). \tag{4}$$

The general finite sum of integral POWERS can be given by the expression

$$\sum_{k=1}^{n} k^p = \frac{(B+n+1)^{[p+1]} - B^{[p+1]}}{p+1}, \tag{5}$$

where the NOTATION $B^{[k]}$ means the quantity in question is raised to the appropriate POWER k and all terms of the form B^m are replaced with the corresponding BERNOULLI NUMBERS B_m. It is also true that the COEFFICIENTS of the terms in such an expansion sum to 1, as stated by Bernoulli without proof (Boyer 1943).

An analytic solution for a sum of POWERS of integers is

$$\sum_{k=1}^{n} k^p = \zeta(-p) - \zeta(-p, 1+n), \tag{6}$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION and $\zeta(z;a)$ is the HURWITZ ZETA FUNCTION. For the special case of p a POSITIVE integer, FAULHABER'S FORMULA gives the SUM explicitly as

$$\sum_{k=1}^{n} k^p = \frac{1}{p+1}\sum_{k=1}^{p+1}(-1)^{\delta_{kp}}\binom{p+1}{k}B_{p+1-k}n^k, \tag{7}$$

where δ_{kp} is the KRONECKER DELTA, $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, and B_k is a BERNOULLI NUMBER. Written explicitly in terms of a sum of POWERS,

$$\sum_{k=1}^{n} k^p = \frac{B_k p!}{k!(p-k+1)!}n^{p-k+1}. \tag{8}$$

Computing the sums for $p = 1, \ldots, 10$ gives

$$\sum_{k=1}^{n} k = \tfrac{1}{2}(n^2+n) \tag{9}$$

$$\sum_{k=1}^{n} k^2 = \tfrac{1}{6}(2n^3+3n^2+n) \tag{10}$$

$$\sum_{k=1}^{n} k^3 = \tfrac{1}{4}(n^4+2n^3+n^2) \tag{11}$$

$$\sum_{k=1}^{n} k^4 = \tfrac{1}{30}(6n^5+15n^4+10n^3-n) \tag{12}$$

$$\sum_{k=1}^{n} k^5 = \tfrac{1}{12}(2n^6+6n^5+5n^4-n^2) \tag{13}$$

$$\sum_{k=1}^{n} k^6 = \tfrac{1}{42}(6n^7 + 21n^6 + 21n^5 - 7n^3 + n) \quad (14)$$

$$\sum_{k=1}^{n} k^7 = \tfrac{1}{24}(3n^8 + 12n^7 + 14n^6 - 7n^4 + 2n^2) \quad (15)$$

$$\sum_{k=1}^{n} k^8 = \tfrac{1}{90}(10n^9 + 45n^8 + 60n^7 - 42n^5 + 20n^3 - 3n) \quad (16)$$

$$\sum_{k=1}^{n} k^9 = \tfrac{1}{20}(2n^{10} + 10n^9 + 15n^8 - 14n^6 + 10n^4 - 3n^2) \quad (17)$$

$$\sum_{k=1}^{n} k^{10} = \tfrac{1}{66}(6n^{11} + 33n^{10} + 55n^9 - 66n^7 + 66n^5 - 33n^3 + 5n). \quad (18)$$

Factoring the above equations results in

$$\sum_{k=1}^{n} k = \tfrac{1}{2}n(n+1) \quad (19)$$

$$\sum_{k=1}^{n} k^2 = \tfrac{1}{6}n(n+1)(2n+1) \quad (20)$$

$$\sum_{k=1}^{n} k^3 = \tfrac{1}{4}n^2(n+1)^2 \quad (21)$$

$$\sum_{k=1}^{n} k^4 = \tfrac{1}{30}n(n+1)(2n+1)(3n^2+3n-1) \quad (22)$$

$$\sum_{k=1}^{n} k^5 = \tfrac{1}{12}n^2(n+1)^2(2n^2+2n-1) \quad (23)$$

$$\sum_{k=1}^{n} k^6 = \tfrac{1}{42}n(n+1)(2n+1)(3n^4+6n^3-3n+1) \quad (24)$$

$$\sum_{k=1}^{n} k^7 = \tfrac{1}{24}n^2(n+1)^2(3n^4+6n^3-n^2-4n+2) \quad (25)$$

$$\sum_{k=1}^{n} k^8 = \tfrac{1}{90}n(n+1)(2n+1)(5n^6+15n^5+5n^4 -15n^3-n^2+9n-3) \quad (26)$$

$$\sum_{k=1}^{n} k^9 = \tfrac{1}{20}n^2(n+1)^2(n^2+n-1) \times(2n^4+4n^3-n^2-3n+3) \quad (27)$$

$$\sum_{k=1}^{n} k^{10} = \tfrac{1}{66}n(n+1)(2n+1)(n^2+n-1) \times(3n^6+9n^5+2n^4-11n^3+3n^2+10n-5). \quad (28)$$

From the above, note the interesting identity

$$\sum_{k=1}^{n} k^3 = \left(\sum_{k=1}^{n} k\right)^2. \quad (29)$$

Sums of the following type can also be done analytically.

$$\left(\sum_{k=0}^{\infty} x^k\right)^2 = \sum_{n=0}^{\infty}\left(\sum_{k=0}^{n} 1\right) x^n = \sum_{n=0}^{\infty}(n+1)x^n \quad (30)$$

$$\begin{aligned}\left(\sum_{k=0}^{\infty} x^k\right)^3 &= \sum_{n=0}^{\infty}\left(\sum_{k=0}^{n} k\right) x^n \\ &= \frac{1}{2}\sum_{n=0}^{\infty}(n+1)(n+2)x^n \quad (31)\end{aligned}$$

$$\begin{aligned}\left(\sum_{k=0}^{\infty} x^k\right)^4 &= \sum_{n=0}^{\infty}\left[\sum_{k=0}^{n} \tfrac{1}{2}(k+1)(k+2)\right] x^n \\ &= \frac{1}{2}\sum_{n=0}^{\infty}\left(\sum_{k=0}^{n} k^2+3k+2\right) x^n \\ &= \frac{1}{2}\sum_{n=0}^{\infty}[\tfrac{1}{6}n(n+1)(2n+1) \\ &\quad + 3\tfrac{1}{2}n(n+1) + 2(n+1)]x^n \\ &= \frac{1}{12}\sum_{n=0}^{\infty}(n+1)[n(2n+1)+9n+12]x^n \\ &= \frac{1}{12}\sum_{n=0}^{\infty}(n+1)(2n^2+10n+12)x^n \\ &= \frac{1}{6}\sum_{n=0}^{\infty}(n+1)(n+2)(n+3)x^n. \quad (32)\end{aligned}$$

By INDUCTION, the sum for an arbitrary POWER p is

$$\left(\sum_{k=0}^{\infty} x^k\right)^p = \frac{1}{(p-1)!}\sum_{n=0}^{\infty}\frac{(n+p-1)!}{n!}x^n. \quad (33)$$

Other analytic sums include

$$\left(\sum_{k=0}^{n} x^k\right)^2 = \frac{1}{(p-1)!}\sum_{k=0}^{2n}\frac{(n-|n-k|+p-1)!}{(n-|n-k|)!}x^k \quad (34)$$

$$\left(\sum_{n=0}^{\infty} a_n x^n\right)^2 = \sum_{n=0}^{\infty} {a_n}^2 x^{2n} + 2\sum_{\substack{n=1\\ i+j=n\\ i<j}}^{\infty} a_i a_j x^n. \quad (35)$$

$$\begin{aligned}\sum xy &= x_1y_1 + x_1y_2 + \ldots + x_2y_1 + x_2y_2 + \ldots \\ &= (x_1+x_2+\ldots)y_1 + (x_1+x_2+\ldots)y_2 \\ &= \left(\sum x\right)(y_1+y_2+\ldots) = \sum x \sum y, \quad (36)\end{aligned}$$

so

$$\sum_{i=1}^{m}\sum_{j=1}^{n} x_i y_j = \left(\sum_{i=1}^{m} x_i\right)\left(\sum_{j=1}^{n} y_j\right). \tag{37}$$

$$\sum_{j=0}^{n} j x^j = \frac{n x^{n+2} - (n+1)x^{n+1} + x}{(x-1)^2} \tag{38}$$

$$\sum_{j=1}^{n} \frac{{x_j}^r}{\prod_{\substack{k=1\\k\neq j}}^{n} (x_j - x_k)} = \begin{cases} 0 & \text{for } 0 \leq r < n-1 \\ 1 & \text{for } r = n-1 \\ \sum_{j=1}^{n} x_j & \text{for } r = n \end{cases} \tag{39}$$

$$\sum_{k=1}^{n} \frac{\prod_{\substack{r=1\\r\neq k}}^{n} (x+k-r)}{\prod_{\substack{r=1\\r\neq k}}^{n} (k-r)} = 1 \tag{40}$$

$$(n+1)\sum_{m=1}^{n} m^k = \sum_{m=1}^{n}\left[m^{k+1} + \sum_{p=1}^{n}\left(\sum_{m=1}^{p} m^k\right)\right]. \tag{41}$$

To minimize the sum of a set of squares of numbers $\{x_i\}$ about a given number x_0

$$S \equiv \sum_i (x_i - x_0)^2 = \sum_i {x_i}^2 - 2x_0 \sum x_i + N{x_0}^2, \tag{42}$$

take the DERIVATIVE.

$$\frac{d}{dx_0} S = -2\sum_i x_i + 2Nx_0 = 0. \tag{43}$$

Solving for x_0 gives

$$x_0 \equiv \bar{x} = \frac{1}{N}\sum_i x_i, \tag{44}$$

so S is maximized when x_0 is set to the MEAN.

Sum-Product Number

A sum-product number is a number n such that the sum of n's digits times the product of n's digit is n itself, for example

$$135 = (1+3+5)(1 \cdot 3 \cdot 5).$$

The only sum-product numbers less than 10^7 are 1, 135, and 144.

see also AMENABLE NUMBER

Sum Rule

$$\frac{d}{dx}[f(x) + g(x)] = f'(x) + g'(x),$$

where d/dx denotes a derivative and $f'(x)$ and $g'(x)$ are the derivatives of f and g, respectively.

Super-3 Number

An INTEGER n such that $3n^3$ contains three consecutive 3s in its DECIMAL representation. The first few super-3 numbers are 261, 462, 471, 481, 558, 753, 1036, ... (Sloane's A014569). A. Anderson has conjectured that all numbers ending in 471, 4710, or 47100 are super-3 (Pickover 1995).

For a digit d, super-3 numbers can be generalized to super-d numbers n such that dn^d contains d ds in its DECIMAL representation. The following table gives the first few super-d numbers for small d.

d	Sloane	Super-d numbers
2	032743	19, 31, 69, 81, 105, 106, 107, 119, ...
3	014569	261, 462, 471, 481, 558, 753, 1036, ...
4	032744	1168, 4972, 7423, 7752, 8431, 10267, ...
5	032745	4602, 5517, 7539, 12955, 14555, 20137, ...
6	032746	27257, 272570, 302693, 323576, ...
7	032747	140997, 490996, 1184321, 1259609, ...
8	032748	185423, 641519, 1551728, 1854230, ...
9	032749	17546133, 32613656, 93568867, ...

Super Catalan Number

While the CATALAN NUMBERS are the number of p-GOOD PATHS from (n,n) to (0,0) which do not cross the diagonal line, the super Catalan numbers count the number of LATTICE PATHS with diagonal steps from (n,n) to (0,0) which do not touch the diagonal line $x = y$.

The super Catalan numbers are given by the RECURRENCE RELATION

$$S(n) = \frac{3(2n-3)S(n-1)-(n-3)S(n-2)}{n}$$

(Comtet 1974), with $S(1) = S(2) = 1$. (Note that the expression in Vardi (1991, p. 198) contains *two* errors.) A closed form expression in terms of LEGENDRE POLYNOMIALS $P_n(x)$ is

$$S(n) = \frac{3P_{n-1}(3) - P_{n-2}(3)}{4n}$$

(Vardi 1991, p. 199). The first few super Catalan numbers are 1, 1, 3, 11, 45, 197, ... (Sloane's A001003).

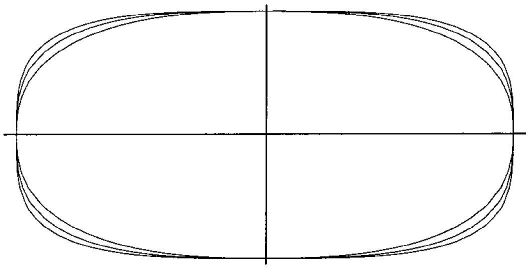
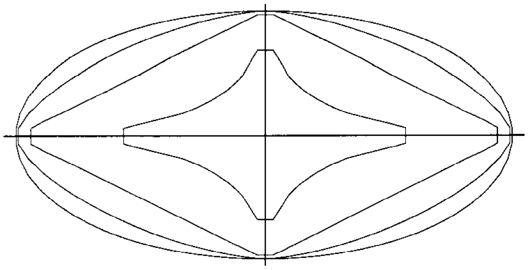
Superellipse



A curve of the form

$$\left|\frac{x}{a}\right|^r + \left|\frac{y}{b}\right|^r = 1.$$

where $r > 2$. "The" superellipse is sometimes taken as the curve of the above form with $r = 5/2$. Superellipses with $a = b$ are also known as LAMÉ CURVES. The above curves are for $a = 1$, $b = 2$, and $r = 2.5$, 3.0, and 3.5.



A degenerate superellipse is a superellipse with $r \leq 2$. The above curves are for $a = 1$, $b = 2$, and $r = 0.5$, 1.0, 1.5, and 2.0.

Superfactorial

The superfactorial of n is defined by Pickover (1995) as

$$n\$ \equiv \underbrace{n!^{n!^{\cdot^{\cdot^{\cdot^{n!}}}}}}_{n!}.$$

The first two values are 1 and 4, but subsequently grow so rapidly that 3$ already has a huge number of digits.

Sloane and Plouffe (1995) define the superfactorial by

$$n\$ \equiv \prod_{i=1}^{n} i!,$$

which is equivalent to the integral values of the G-FUNCTION. The first few values are 1, 1, 2, 12, 288, 34560, ... (Sloane's A000178).

Supernormal

Trials for which the LEXIS RATIO

$$L \equiv \frac{\sigma}{\sigma_B},$$

satisfies $L > 1$, where σ is the VARIANCE in a set of s LEXIS TRIALS and σ_B is the VARIANCE assuming BERNOULLI TRIALS.

see also BERNOULLI TRIAL, LEXIS TRIALS, SUBNORMAL

Superperfect Number

A number n such that

$$\sigma^2(n) = \sigma(\sigma(n)) = 2n,$$

where $\sigma(n)$ is the DIVISOR FUNCTION. EVEN superperfect numbers are just 2^{p-1}, where $M_p = 2^p - 1$ is a MERSENNE PRIME. If any ODD superperfect numbers exist, they are SQUARE NUMBERS and either n or $\sigma(n)$ is DIVISIBLE by at least three distinct PRIMES.

More generally, an m-superperfect number is a number for which $\sigma^m(n) = 2n$. For $m \geq 3$, there are no EVEN m-superperfect numbers.

see also MERSENNE NUMBER

Superposition Principle

For a linear homogeneous ORDINARY DIFFERENTIAL EQUATION, if $y_1(x)$ and $y_2(x)$ are solutions, then so is $y_1(x) + y_2(x)$.

Superregular Graph

For a VERTEX x of a GRAPH, let Γ_x and Δ_x denote the SUBGRAPHS of $\Gamma - x$ induced by the VERTICES adjacent to and nonadjacent to x, respectively. The empty graph is defined to be superregular, and Γ is said to be superregular if Γ is a REGULAR GRAPH and both Γ_x and Δ_x are superregular for all x.

The superregular graphs are precisely C_5, mK_n $(m, n \geq 1)$, G_n $(n \geq 1)$, and the complements of these graphs, where C_n is a CYCLIC GRAPH, K_n is a COMPLETE GRAPH and mK_n is m disjoint copies of K_n, and G_n is the Cartesian product of K_n with itself (the graph whose VERTEX set consists of n^2 VERTICES arranged in an $n \times n$ square with two VERTICES adjacent IFF they are in the same row or column).

Superscript

A quantity displayed above the normal line of text (and generally in a smaller point size), as the "i" in x^i, is called a superscript. Superscripts are commonly used to indicate raising to a POWER (x^3 means $x \cdot x \cdot x$ or x CUBED), multiple differentiation ($f^{(3)}(x)$ is an abbreviation for $f'''(x) = d^3f/dx^3$), and a host of other operations and notations in mathematics.

see also SUBSCRIPT

Superset

A SET containing all elements of a smaller SET. If B is a SUBSET of A, then A is a superset of B, written $A \supseteq B$. If A is a PROPER SUPERSET of B, this is written $A \supset B$.

see also PROPER SUBSET, PROPER SUPERSET, SUBSET

Supplementary Angle

Two ANGLES α and $\pi - \alpha$ which together form a STRAIGHT ANGLE are said to be supplementary.

see also ANGLE, COMPLEMENTARY ANGLE, DIGON, STRAIGHT ANGLE

Support

The CLOSURE of the SET of arguments of a FUNCTION f for which f is not zero.

see also CLOSURE

Support Function

Let M be an oriented REGULAR SURFACE in $\mathbb{R}^3$ with normal $\mathbf{N}$. Then the support function of M is the function $h : M \to \mathbb{R}$ defined by

$$h(\mathbf{p}) = \mathbf{p} \cdot \mathbf{N}(\mathbf{p}).$$

Supremum

The supremum of a set is the least upper bound of the set. It is denoted

$$\sup_S .$$

On the REAL LINE, the supremum of a set is the same as the supremum of its CLOSURE.

see also INFIMUM, SUPREMUM LIMIT

Supremum Limit

The limit supremum is used for sequences and nets (as opposed to sets) and is denoted

$$\limsup_S .$$

see also SUPREMUM

Surd

An archaic term for a SQUARE ROOT.

see also QUADRATIC SURD, SQUARE ROOT

Surface

The word "surface" is an important term in mathematics and is used in many ways. The most common and straightforward use of the word is to denote a 2-D SUBMANIFOLD of 3-D EUCLIDEAN SPACE. Surfaces can range from the very complicated (e.g., FRACTALS such as the MANDELBROT SET) to the very simple (such as the PLANE). More generally, the word "surface" can be used to denote an $(n-1)$-D SUBMANIFOLD of an n-D MANIFOLD, or in general, any co-dimension 1 subobject in an object (like a BANACH SPACE or an infinite-dimensional MANIFOLD).

Even simple surfaces can display surprisingly counterintuitive properties. For example, the SURFACE OF REVOLUTION of $y = 1/x$ around the x-AXIS for $x \geq 1$ (called GABRIEL'S HORN) has FINITE VOLUME but INFINITE SURFACE AREA.

Surface Area

Surface area is the AREA of a given surface. Roughly speaking, it is the "amount" of a surface, and has units of distance squares. It is commonly denoted S for a surface in 3-D, or A for a region of the plane (in which case it is simply called "the" AREA).

If the surface is PARAMETERIZED using u and v, then

$$S = \int_S |\mathbf{T}_u \times \mathbf{T}_v|\, du\, dv, \tag{1}$$

where $\mathbf{T}_u$ and $\hat{\mathbf{T}}_v$ are tangent vectors and $\mathbf{a} \times \mathbf{b}$ is the CROSS PRODUCT.

The surface area given by rotating the curve $y = f(x)$ from $x = a$ to $x = b$ about the x-axis is

$$S = \int_b^a 2\pi f(x)\sqrt{1 + [f'(x)]^2}\, dx. \tag{2}$$

If $z = f(x, y)$ is defined over a region R, then

$$S = \iint_R \sqrt{\left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2 + 1}\, dA, \tag{3}$$

where the integral is taken over the entire surface.

The following tables gives surface areas for some common SURFACES. In the first table, S denotes the lateral surface, and in the second, T denotes the total surface. In both tables, r denotes the RADIUS, h the height, p the base PERIMETER, and s the SLANT HEIGHT (Beyer 1987).

Surface	S
cone	$\pi r\sqrt{r^2 + h^2}$
conical frustum	$\pi(R_1 + R_2)\sqrt{(R_1 - R_2)^2 + h^2}$
cube	$6a^2$
cylinder	$2\pi rh$
lune	$2r^2\theta$
oblate spheroid	$2\pi a^2 + \frac{\pi b^2}{e}\ln\left(\frac{1+e}{1-e}\right)$
prolate spheroid	$2\pi b^2 + \frac{2\pi ab}{e}\sin^{-1} e$
pyramid	$\frac{1}{2}ps$
pyramidal frustum	$\frac{1}{2}ps$
sphere	$4\pi r^2$
torus	$4\pi^2 Rr$
zone	$2\pi rh$

Surface	T
cone	$\pi r(r + \sqrt{r^2 + h^2})$
conical frustum	$\pi[{R_1}^2 + {R_2}^2 + (R_1 + R_2)\sqrt{(R_1 - R_2)^2 + h^2}]$
cylinder	$2\pi r(r + h)$

Even simple surfaces can display surprisingly counterintuitive properties. For instance, the surface of revolution of $y = 1/x$ around the x-AXIS for $x \geq 1$ is called GABRIEL'S HORN, and has FINITE VOLUME but INFINITE surface AREA.

see also AREA, SURFACE INTEGRAL, SURFACE OF REVOLUTION, VOLUME

Surface Integral

For a SCALAR FUNCTION f over a surface parameterized by u and v, the surface integral is given by

$$\Phi = \int_S f\, da = \int_S f(u, v)\, |\mathbf{T}_u \times \mathbf{T}_v|\, du\, dv, \tag{1}$$

where $\mathbf{T}_u$ and $\hat{\mathbf{T}}_v$ are tangent vectors and $\mathbf{a} \times \mathbf{b}$ is the CROSS PRODUCT.

For a VECTOR FUNCTION over a surface, the surface integral is given by

$$\Phi = \int_S \mathbf{F} \cdot d\mathbf{a} = \int_S (\mathbf{F} \cdot \hat{\mathbf{n}})\, da \tag{2}$$

$$= \int_S f_x\, dy\, dz + f_y\, dz\, dx + f_z\, dx\, dy, \tag{3}$$

where $\mathbf{a} \cdot \mathbf{b}$ is a DOT PRODUCT and $\hat{\mathbf{n}}$ is a unit NORMAL VECTOR. If $z = f(x, y)$, then $d\mathbf{a}$ is given explicitly by

$$d\mathbf{a} = \pm\left(-\frac{\partial z}{\partial x}\hat{\mathbf{x}} - \frac{\partial z}{\partial y}\hat{\mathbf{y}} + \hat{\mathbf{z}}\right) dx\, dy. \tag{4}$$

If the surface is SURFACE PARAMETERIZED using u and v, then

$$\Phi = \int_S \mathbf{F} \cdot (\mathbf{T}_u \times \mathbf{T}_v)\, du\, dv. \tag{5}$$

see also SURFACE PARAMETERIZATION

Surface Parameterization

A surface in 3-Space can be parameterized by two variables (or coordinates) u and v such that

$$x = x(u, v) \tag{1}$$

$$y = y(u, v) \tag{2}$$

$$z = z(u, v). \tag{3}$$

If a surface is parameterized as above, then the tangent Vectors

$$\mathbf{T}_u = \frac{\partial x}{\partial u}\hat{\mathbf{x}} + \frac{\partial y}{\partial u}\hat{\mathbf{y}} + \frac{\partial z}{\partial u}\hat{\mathbf{z}} \tag{4}$$

$$\mathbf{T}_v = \frac{\partial x}{\partial v}\hat{\mathbf{x}} + \frac{\partial y}{\partial v}\hat{\mathbf{y}} + \frac{\partial z}{\partial v}\hat{\mathbf{z}} \tag{5}$$

are useful in computing the Surface Area and Surface Integral.

see also Smooth Surface, Surface Area, Surface Integral

Surface of Revolution

A surface of revolution is a Surface generated by rotating a 2-D Curve about an axis. The resulting surface therefore always has azimuthal symmetry. Examples of surfaces of revolution include the Apple, Cone (excluding the base), Conical Frustum (excluding the ends), Cylinder (excluding the ends), Darwin-de Sitter Spheroid, Gabriel's Horn, Hyperboloid, Lemon, Oblate Spheroid, Paraboloid, Prolate Spheroid, Pseudosphere, Sphere, Spheroid, and Torus (and its generalization, the Toroid).

The standard parameterization of a surface of revolution is given by

$$x(u, v) = \phi(v)\cos u \tag{1}$$

$$y(u, v) = \phi(v)\sin u \tag{2}$$

$$z(u, v) = \psi(v). \tag{3}$$

For a curve so parameterized, the first Fundamental Form has

$$E = \psi^2 \tag{4}$$

$$F = 0 \tag{5}$$

$$G = \phi'^2 + \psi'^2. \tag{6}$$

Wherever ϕ and $\phi'^2 + \psi'^2$ are nonzero, then the surface is regular and the second Fundamental Form has

$$e = -\frac{|\phi|\psi'}{\sqrt{\phi'^2 + \psi'^2}} \tag{7}$$

$$f = 0 \tag{8}$$

$$g = \frac{\operatorname{sgn}(\phi)(\phi''\psi' - \phi'\psi'')}{\sqrt{\phi'^2 + \psi'^2}}. \tag{9}$$

Furthermore, the unit Normal Vector is

$$\hat{\mathbf{N}}(u, v) = \frac{\operatorname{sgn}(\phi)}{\sqrt{\phi'^2 + \psi'^2}} \begin{bmatrix} \phi'\cos u \\ \psi'\sin u \\ \phi' \end{bmatrix}, \tag{10}$$

and the Principal Curvatures are

$$\kappa_1 = \frac{g}{G} = \frac{\operatorname{sgn}(\phi)(\phi''\psi' - \phi'\psi'')}{(\phi'^2 + \psi'^2)^{3/2}} \tag{11}$$

$$\kappa_2 = \frac{e}{E} = -\frac{\psi'}{|\phi|\sqrt{\phi'^2 + \psi'^2}}. \tag{12}$$

The Gaussian and Mean Curvatures are

$$K = \frac{-\psi'^2\phi'' + \phi'\psi'\psi''}{\phi(\phi'^2 + \psi'^2)^2} \tag{13}$$

$$H = \frac{\phi(\phi''\psi' - \phi'\psi'') - \psi'(\phi'^2 + \psi'^2)}{2|\phi|(\phi'^2 + \psi'^2)^{3/2}} \tag{14}$$

(Gray 1993).

Pappus's Centroid Theorem gives the Volume of a solid of rotation as the cross-sectional Area times the distance traveled by the centroid as it is rotated.

Calculus of Variations can be used to find the curve from a point (x_1, y_1) to a point (x_2, y_2) which, when revolved around the x-Axis, yields a surface of smallest Surface Area A (i.e., the Minimal Surface). This is equivalent to finding the Minimal Surface passing through two circular wire frames. The Area element is

$$dA = 2\pi y\, ds = 2\pi y\sqrt{1 + y'^2}\, dx, \tag{15}$$

so the Surface Area is

$$A = 2\pi \int y\sqrt{1 + y'^2}\, dx, \tag{16}$$

and the quantity we are minimizing is

$$f = y\sqrt{1 + y'^2}. \tag{17}$$

This equation has $f_x = 0$, so we can use the Beltrami Identity

$$f - y_x \frac{\partial f}{\partial y_x} = a \tag{18}$$

to obtain

$$y\sqrt{1 + y'^2} - y'\frac{yy'}{\sqrt{1 + y'^2}} = a \tag{19}$$

$$y(1 + y'^2) - yy'^2 = a\sqrt{1 + y'^2} \tag{20}$$

$$y = a\sqrt{1 + y'^2} \tag{21}$$

$$\frac{y}{\sqrt{1 + y'^2}} = a \tag{22}$$

$$\frac{y^2}{a} - 1 = y'^2 \tag{23}$$

$$\frac{dx}{dy} = \frac{1}{y'} = \frac{a}{\sqrt{y^2 - a^2}} \tag{24}$$

$$x = a \int \frac{dy}{\sqrt{y^2 - a^2}} = a \cosh^{-1}\left(\frac{y}{a}\right) + b \tag{25}$$

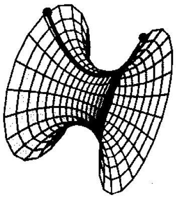
$$y = a \cosh\left(\frac{x - b}{a}\right), \tag{26}$$

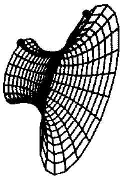
which is called a CATENARY, and the surface generated by rotating it is called a CATENOID. The two constants a and b are determined from the two implicit equations

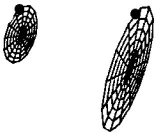
$$y_1 = a \cosh\left(\frac{x_1 - b}{a}\right) \tag{27}$$

$$y_2 = a \cosh\left(\frac{x_2 - b}{a}\right), \tag{28}$$

which cannot be solved analytically.







The general case is somewhat more complicated than this solution suggests. To see this, consider the MINIMAL SURFACE between two rings of equal RADIUS y_0. Without loss of generality, take the origin at the midpoint of the two rings. Then the two endpoints are located at $(-x_0, y_0)$ and (x_0, y_0), and

$$y_0 = a \cosh\left(\frac{-x_0 - b}{a}\right) = a \cosh\left(\frac{x_0 - b}{a}\right). \tag{29}$$

But $\cosh(-x) = \cosh(x)$, so

$$\cosh\left(\frac{-x_0 - b}{a}\right) = \cosh\left(\frac{-x_0 + b}{a}\right). \tag{30}$$

Inverting each side

$$-x_0 - b = -x_0 + b, \tag{31}$$

so $b = 0$ (as it must by symmetry, since we have chosen the origin between the two rings), and the equation of the MINIMAL SURFACE reduces to

$$y = a \cosh\left(\frac{x}{a}\right). \tag{32}$$

At the endpoints

$$y_0 = a \cosh\left(\frac{x_0}{a}\right), \tag{33}$$

but for certain values of x_0 and y_0, this equation has no solutions. The physical interpretation of this fact is that the surface breaks and forms circular disks in each ring to minimize AREA. CALCULUS OF VARIATIONS cannot be used to find such discontinuous solutions (known in this case as GOLDSCHMIDT SOLUTIONS). The minimal surfaces for several choices of endpoints are shown above. The first two cases are CATENOIDS, while the third case is a GOLDSCHMIDT SOLUTION.

To find the maximum value of x_0/y_0 at which CATENARY solutions can be obtained, let $p \equiv 1/a$. Then (31) gives

$$y_0 p = \cosh(p x_0). \tag{34}$$

Now, denote the maximum value of x_0 as x_0^*. Then it will be true that $dx_0/dp = 0$. Take d/dp of (34),

$$y_0 = \sinh(p x_0)\left(x_0 + p\frac{dx_0}{dp}\right). \tag{35}$$

Now set $dx_0/dp = 0$

$$y_0 = x_0 \sinh(p x_0^*). \tag{36}$$

From (34),

$$p y_0{}^* = \cosh(p x_0{}^*). \tag{37}$$

Take (37) ÷ (36),

$$p x_0^* = \coth(p x_0^*). \tag{38}$$

Defining $u \equiv p x_0{}^*$,

$$u = \coth u. \tag{39}$$

This has solution $u = 1.1996789403\ldots$. From (36), $y_0 p = \cosh u$. Divide this by (39) to obtain $y_0/x_0 = \sinh u$, so the maximum possible value of x_0/y_0 is

$$\frac{x_0}{y_0} = \operatorname{csch} u = 0.6627434193\ldots. \tag{40}$$

Therefore, only Goldschmidt ring solutions exist for $x_0/y_0 > 0.6627\ldots$.

The SURFACE AREA of the minimal CATENOID surface is given by

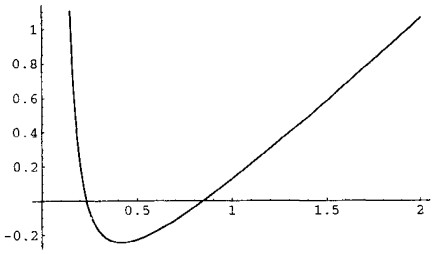
$$A = 2(2\pi)\int_0^{x_0} y\sqrt{1 + y'^2}\, dx, \tag{41}$$

but since

$$y = \sqrt{1 + y'^2}\, a \tag{42}$$

$$y = a \cosh\left(\frac{x}{a}\right), \tag{43}$$

$$\begin{aligned}A &= \frac{4\pi}{a}\int_0^{x_0} y^2\,dx = 4\pi a\int_0^{x_0}\cosh^2\left(\frac{x}{a}\right)dx\\ &= 4\pi a\int_0^{x_0}\tfrac{1}{2}\left[\cosh\left(\frac{2x}{a}\right)+1\right]dx\\ &= 2\pi a\left[\int_0^{x_0}\cosh\left(\frac{2x}{a}\right)dx+\int_0^{x_0}dx\right]\\ &= 2\pi a\left[\frac{a}{2}\sinh\left(\frac{2x}{a}\right)+x\right]_0^{x_0}\\ &= \pi a^2\left[\sinh\left(\frac{2x}{a}\right)+\frac{2x}{a}\right]_0^{x_0}\\ &= \pi a^2\left[\sinh\left(\frac{2x_0}{a}\right)+\frac{2x_0}{a}\right].\end{aligned}\tag{44}$$



Some caution is needed in solving (33) for a. If we take $x_0 = 1/2$ and $y_0 = 1$ then (33) becomes

$$1 = a\cosh\left(\frac{1}{2a}\right),\tag{45}$$

which has *two* solutions: $a_1 = 0.2350\ldots$ ("deep"), and $a_2 = 0.8483\ldots$ ("flat"). However, upon plugging these into (44) with $x_0 = 1/2$, we find $A_1 = 6.8456\ldots$ and $A_2 = 5.9917\ldots$. So A_1 is *not,* in fact, a local minimum, and A_2 is the only *true* minimal solution.

The SURFACE AREA of the CATENOID solution equals that of the GOLDSCHMIDT SOLUTION when (44) equals the AREA of two disks,

$$\pi a^2\left[\sinh\left(\frac{2x_0}{a}\right)+\frac{2x_0}{a}\right] = 2\pi{y_0}^2\tag{46}$$

$$a^2\left[2\sinh\left(\frac{x_0}{a}\right)\cosh\left(\frac{x_0}{a}\right)+\frac{2x_0}{a}\right]-2{y_0}^2 = 0\tag{47}$$

$$a^2\left[\cosh\left(\frac{x_0}{a}\right)\sqrt{\cosh^2\left(\frac{x_0}{a}\right)-1}+\frac{x_0}{a}\right]-{y_0}^2 = 0.\tag{48}$$

Plugging in

$$\frac{y_0}{a} = \cosh\left(\frac{x_0}{a}\right),\tag{49}$$

$$\frac{y_0}{a}\sqrt{\left(\frac{y_0}{a}\right)^2-1}+\cosh^{-1}\left(\frac{y_0}{a}\right)-\left(\frac{y_0}{a}\right)^2 = 0.\tag{50}$$

Defining

$$u \equiv \frac{y_0}{a}\tag{51}$$

gives

$$u\sqrt{u^2-1}+\cosh^{-1}u-u^2 = 0.\tag{52}$$

This has a solution $u = 1.2113614259$. The value of x_0/y_0 for which

$$A_{\text{catenary}} = A_{2\text{ disks}}\tag{53}$$

is therefore

$$\frac{x_0}{y_0} = \frac{\frac{x_0}{a}}{\frac{y_0}{a}} = \frac{\cosh^{-1}\left(\frac{y_0}{a}\right)}{\frac{y_0}{a}} = \frac{\cosh^{-1}u}{u} = 0.5276973967.\tag{54}$$

For $x_0/y_0 \in (0.52770, 0.6627)$, the CATENARY solution has larger AREA than the two disks, so it exists only as a RELATIVE MINIMUM.

There also exist solutions with a disk (of radius r) between the rings supported by two CATENOIDS of revolution. The AREA is larger than that for a simple CATENOID, but it is a RELATIVE MINIMUM. The equation of the POSITIVE half of this curve is

$$y = c_1\cosh\left(\frac{x}{c_1}+c_3\right).\tag{55}$$

At $(0, r)$,

$$r = c_1\cosh(c_3).\tag{56}$$

At (x_0, y_0),

$$y_0 = c_1\cosh\left(\frac{x_0}{c_1}+c_3\right).\tag{57}$$

The AREA of the two CATENOIDS is

$$\begin{aligned}A_{\text{catenoids}} &= 2(2\pi)\int_0^{x_0} y\sqrt{1+y'^2}\,dx = \frac{4\pi}{c_1}\int_0^{x_0} y^2\,dx\\ &= 4\pi c_1\int_0^{x_0}\cosh^2\left(\frac{x}{c_1}+c_3\right)dx.\end{aligned}\tag{58}$$

Now let $u \equiv x/c_1 + c_3$, so $du = dx/c_1$

$$\begin{aligned}A &= 4\pi{c_1}^2\int_{c_3}^{x_0/x_1+c_3}\cosh^2 u\,du\\ &= 4\pi{c_1}^2\tfrac{1}{2}\int_{c_3}^{x_0/x_1+c_3}[\cosh(2u)+1]\,du\\ &= 2\pi{c_1}^2\left[\tfrac{1}{2}\sinh(2u)+u\right]_{c_3}^{x_0/x_1+c_3}\\ &= 2\pi{c_1}^2\left\{\tfrac{1}{2}\sinh\left[2\left(\frac{x_0}{c_1}+c_3\right)\right]-\tfrac{1}{2}\sinh(2c_3)+\frac{x_0}{c_1}\right\}\\ &= \pi{c_1}^2\left\{\sinh\left[2\left(\frac{x_0}{c_1}+c_3\right)\right]-\sinh(2c_3)+\frac{2x_0}{c_1}\right\}.\end{aligned}\tag{59}$$

The AREA of the central DISK is

$$A_{\text{disk}} = \pi r^2 = \pi{c_1}^2\cosh^2 c_3,\tag{60}$$

so the total AREA is

$$\begin{aligned} A = \pi {c_1}^2 \biggl\{ & \sinh\left[2\left(\frac{x_0}{c_1}+c_3\right)\right] \\ & + \left[\cosh^2 c_3 - \sinh(2c_3)\right] + \frac{2x_0}{c_1}\biggr\}. \end{aligned} \tag{61}$$

By PLATEAU'S LAWS, the CATENOIDS meet at an ANGLE of 120°, so

$$\begin{aligned} \tan 30^\circ &= \left[\frac{dy}{dx}\right]_{x=0} = \left[\sinh\left(\frac{x}{c_1}+c_3\right)\right]_{x=0} \\ &= \sinh c_3 = \frac{1}{\sqrt{3}} \end{aligned} \tag{62}$$

and

$$c_3 = \sinh^{-1}\left(\frac{1}{\sqrt{3}}\right). \tag{63}$$

This means that

$$\begin{aligned} & \cosh^2 c_3 - \sinh(2c_3) \\ &\quad = [1+\sinh^2 c_3] - 2\sinh c_3 \sqrt{1+\sinh^2 c_3} \\ &\quad = (1+\tfrac{1}{3}) - 2\left(\frac{1}{\sqrt{3}}\right)\sqrt{1+\tfrac{1}{3}} \\ &\quad = \frac{4}{3} - \frac{2}{\sqrt{3}}\frac{2}{\sqrt{3}} = 0, \end{aligned} \tag{64}$$

so

$$A = \pi {c_1}^2 \left\{\sinh\left[2\left(\frac{x_0}{c_1}+c_3\right)\right] + \frac{2x_0}{c_1}\right\}. \tag{65}$$

Now examine x_0/y_0,

$$\frac{x_0}{y_0} = \frac{\frac{x_0}{c_1}}{\frac{y_0}{c_1}} = \frac{\frac{x_0}{c_1}}{\cosh\left(\frac{x_0}{c_1}+c_3\right)} = u \operatorname{sech}(u+c_3), \tag{66}$$

where $u \equiv x_0/c_1$. Finding the maximum ratio of x_0/y_0 gives

$$\frac{d}{du}\left(\frac{x_0}{y_0}\right) = \operatorname{sech}(u+c_3) - u\tanh(u+c_3)\operatorname{sech}(u+c_3) = 0 \tag{67}$$

$$u\tanh(u+c_3) = 1, \tag{68}$$

with $c_3 = \sinh^{-1}(1/\sqrt{3})$ as given above. The solution is $u = 1.0799632187$, so the maximum value of x_0/y_0 for two CATENOIDS with a central disk is $y_0 = 0.4078241702$.

If we are interested instead in finding the curve from a point (x_1, y_1) to a point (x_2, y_2) which, when revolved around the y-AXIS (as opposed to the x-AXIS), yields a surface of smallest SURFACE AREA A, we proceed as above. Note that the solution is physically equivalent to that for rotation about the x-AXIS, but takes on a different mathematical form. The AREA element is

$$dA = 2\pi x\, ds = 2\pi x\sqrt{1+y'^2}\, dx \tag{69}$$

$$A = 2\pi \int x\sqrt{1+y'^2}\, dx, \tag{70}$$

and the quantity we are minimizing is

$$f = x\sqrt{1+y'^2}. \tag{71}$$

Taking the derivatives gives

$$\frac{\partial f}{\partial y} = 0 \tag{72}$$

$$\frac{d}{dx}\frac{\partial f}{\partial y'} = \frac{d}{dx}\left(\frac{xy'}{\sqrt{1+y'^2}}\right), \tag{73}$$

so the EULER-LAGRANGE DIFFERENTIAL EQUATION becomes

$$\frac{\partial f}{\partial y} - \frac{d}{dx}\frac{\partial f}{\partial y'} = \frac{d}{dx}\left(\frac{xy'}{\sqrt{1+y'^2}}\right) = 0. \tag{74}$$

$$\frac{xy'}{\sqrt{1+y'^2}} = a \tag{75}$$

$$x^2 y'^2 = a^2(1+y'^2) \tag{76}$$

$$y'^2(x^2-a^2) = a^2 \tag{77}$$

$$\frac{dy}{dx} = \frac{a}{\sqrt{x^2-a^2}} \tag{78}$$

$$y = a\int \frac{dx}{\sqrt{x^2-a^2}} + b = a\cosh^{-1}\left(\frac{x}{a}\right) + b. \tag{79}$$

Solving for x then gives

$$x = a\cosh\left(\frac{y-b}{a}\right), \tag{80}$$

which is the equation for a CATENARY. The SURFACE AREA of the CATENOID product by rotation is

$$\begin{aligned} A &= 2\pi \int x\sqrt{1+y'^2}\, dx = 2\pi \int x\sqrt{1+\frac{a^2}{x^2-a^2}}\, dx \\ &= 2\pi \int \frac{x}{\sqrt{x^2-a^2}}\sqrt{(x^2-a^2)+a^2}\, dx \\ &= 2\pi \int \frac{x^2\, dx}{\sqrt{x^2-a^2}} \\ &= \left[\frac{x}{2}\sqrt{x^2-a^2} + \frac{a^2}{2}\ln\left(x+\sqrt{x^2-a^2}\right)\right]_{x_1}^{x_2} \\ &= \frac{1}{2}\biggl[x_2\sqrt{{x_2}^2-a^2} - x_1\sqrt{{x_1}^2-a^2} \\ &\quad + a^2\ln\left(\frac{x_2+\sqrt{{x_2}^2-a^2}}{x_1+\sqrt{{x_1}^2-a^2}}\right)\biggr]. \end{aligned} \tag{81}$$

Isenberg (1992, p. 80) discusses finding the MINIMAL SURFACE passing through two rings with axes offset from each other.

Surface of Section

A surface (or "space") of section is a way of presenting a trajectory in n-D PHASE SPACE in an $(n-1)$-D SPACE. By picking one phase element constant and plotting the values of the other elements each time the selected element has the desired value, an intersection surface is obtained. If the equations of motion can be formulated as a MAP in which an explicit FORMULA gives the values of the other elements at successive passages through the selected element value, the time required to compute the surface of section is greatly reduced.

see also PHASE SPACE

Surgery

In the process of attaching a k-HANDLE to a MANIFOLD M, the BOUNDARY of M is modified by a process called $(k-1)$-surgery. Surgery consists of the removal of a TUBULAR NEIGHBORHOOD of a $(k-1)$-SPHERE $\mathbb{S}^{k-1}$ from the BOUNDARIES of M and the $\dim(M)-1$ standard SPHERE, and the gluing together of these two scarred-up objects along their common BOUNDARIES.

Surreal Number

The most natural collection of numbers which includes both the REAL NUMBERS and the infinite ORDINAL NUMBERS of Georg Cantor. They were invented by John H. Conway in 1969. Every REAL NUMBER is surrounded by surreals, which are closer to it than any REAL NUMBER. Knuth (1974) describes the surreal numbers in a work of fiction.

The surreal numbers are written using the NOTATION $\{a|b\}$, where $\{|\}=0$, $\{0|\}=1$ is the simplest number greater than 0, $\{1|\}=2$ is the simplest number greater than 1, etc. Similarly, $\{|0\}=-1$ is the simplest number less than 1, etc. However, 2 can also be represented by $\{1|3\}$, $\{3/2|4\}$, $\{1|\omega\}$, etc.

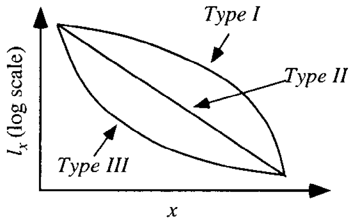
Survivorship Curve



Plotting l_x from a LIFE EXPECTANCY table on a logarithmic scale versus x gives a curve known as a survivorship curve. There are three general classes of survivorship curves, illustrated above.

1. Type I curves are typical of populations in which most mortality occurs among the elderly (e.g., humans in developed countries).
2. Type II curves occur when mortality is not dependent on age (e.g., many species of large birds and fish). For an infinite type II population, $e_0 = e_1 = \ldots$, but this cannot hold for a finite population.
3. Type III curves occur when juvenile mortality is extremely high (e.g., plant and animal species producing many offspring of which few survive). In type III populations, it is often true that $e_{i+1} > e_i$ for small i. In other words, life expectancy increases for individuals who survive their risky juvenile period.

Swinnerton-Dyer Conjecture

In the early 1960s, B. Birch and H. P. F. Swinnerton-Dyer conjectured that if a given ELLIPTIC CURVE has an infinite number of solutions, then the associated L-function has value 0 at a certain fixed point. In 1976, Coates and Wiles showed that elliptic curves with COMPLEX multiplication having an infinite number of solutions have L-functions which are zero at the relevant fixed point (COATES-WILES THEOREM), but they were unable to prove the converse. V. Kolyvagin extended this result to modular curves.

Sylow p-Subgroup

If p^k is the highest POWER of a PRIME p dividing the ORDER of a finite GROUP G, then a SUBGROUP of G of ORDER p^k is called a Sylow p-subgroup of G.

see also ABHYANKAR'S CONJECTURE, SUBGROUP, SYLOW THEOREMS

Sylow Theorems

Let p be a PRIME NUMBER, G a GROUP, and $|G|$ the order of G.

1. If p divides $|G|$, then G has a SYLOW p-SUBGROUP.
2. In a FINITE GROUP, all the SYLOW p-SUBGROUPS are isomorphic for some fixed p.
3. The number of SYLOW p-SUBGROUPS for a fixed p is CONGRUENT to 1 (mod p).

Sylvester Cyclotomic Number

Given a LUCAS SEQUENCE with parameters P and Q, discriminant $D \neq 0$, and roots α and β, the Sylvester cyclotomic numbers are

$$Q_n = \prod_r (\alpha - \zeta^r \beta),$$

where

$$\zeta \equiv \cos\left(\frac{2\pi}{n}\right) + i \sin\left(\frac{2\pi}{n}\right)$$

is a PRIMITIVE ROOT OF UNITY and the product is over all exponents r RELATIVELY PRIME to n such that $r \in [1, n)$.

see also LUCAS SEQUENCE

Sylvester's Inertia Law

The numbers of EIGENVALUES that are POSITIVE, NEGATIVE, or 0 do not change under a congruence transformation. Gradshteyn and Ryzhik (1979) state it as follows: when a QUADRATIC FORM Q in n variables is reduced by a nonsingular linear transformation to the form

$$Q = {y_1}^2 + {y_2}^2 + \ldots + {y_p}^2 - {p_{p+1}}^2 - {y_{p2}}^2 - \ldots - {y_r}^2,$$

the number p of POSITIVE SQUARES appearing in the reduction is an invariant of the QUADRATIC FORM Q and does not depend on the method of reduction.

see also EIGENVALUE, QUADRATIC FORM

Sylvester's Line Problem

It is not possible to arrange a finite number of points so that a LINE through every two of them passes through a third, unless they are all on a single LINE.

see also COLLINEAR, SYLVESTER'S FOUR-POINT PROBLEM

Sylvester Matrix

For POLYNOMIALS of degree m and n, the Sylvester matrix is an $(m+n) \times (m+n)$ matrix whose DETERMINANT is the RESULTANT of the two POLYNOMIALS.

see also RESULTANT

Sylvester's Sequence

The sequence defined by $e_0 = 2$ and the RECURRENCE RELATION

$$e_n = 1 + \prod_{i=0}^{n-1} e_i = {e_{n-1}}^2 - e_{n-1} + 1. \qquad (1)$$

This sequence arises in Euclid's proof that there are an INFINITE number of PRIMES. The proof proceeds by constructing a sequence of PRIMES using the RECURRENCE RELATION

$$e_{n+1} = e_0 e_1 \cdots e_n + 1 \qquad (2)$$

(Vardi 1991). Amazingly, there is a constant

$$E \approx 1.264084735306 \qquad (3)$$

such that

$$e_n = \left\lfloor E^{2^{n+1}} + \tfrac{1}{2} \right\rfloor \qquad (4)$$

(Vardi 1991, Graham *et al.* 1994). The first few numbers in Sylvester's sequence are 2, 3, 7, 43, 1807, 3263443, 10650056950807, ... (Sloane's A000058). The e_n satisfy

$$\sum_{n=0}^{\infty} \frac{1}{e_n} = 1. \tag{5}$$

In addition, if $0 < x < 1$ is an IRRATIONAL NUMBER, then the nth term of an infinite sum of unit fractions used to represent x as computed using the GREEDY ALGORITHM must be smaller than $1/e_n$.

The n of the first few PRIME e_n are 0, 1, 2, 3, 5, ... Vardi (1991) gives a lists of factors less than 5×10^7 of e_n for $n \leq 200$ and shows that e_n is COMPOSITE for $6 \leq n \leq 17$. Furthermore, all numbers less than 2.5×10^{15} in Sylvester's sequence are SQUAREFREE, and no SQUAREFUL numbers in this sequence are known (Vardi 1991).

Symmetric Design

see SYMMETRIC BLOCK DESIGN

Symmetric Function

A symmetric function on n variables x_1, ..., x_n is a function that is unchanged by any PERMUTATION of its variables. In most contexts, the term "symmetric function" refers to a polynomial on n variables with this feature (more properly called a "symmetric polynomial"). Another type of symmetric functions is symmetric rational functions, which are the RATIONAL FUNCTIONS that are unchanged by PERMUTATION of variables.

The symmetric polynomials (respectively, symmetric rational functions) can be expressed as polynomials (respectively, rational functions) in the ELEMENTARY SYMMETRIC FUNCTIONS. This is called the FUNDAMENTAL THEOREM OF SYMMETRIC FUNCTIONS.

A function $f(x)$ is sometimes said to be symmetric about the y-AXIS if $f(-x) = f(x)$. Examples of such functions include $|x|$ (the ABSOLUTE VALUE) and x^2 (the PARABOLA).

see also ELEMENTARY SYMMETRIC FUNCTION, FUNDAMENTAL THEOREM OF SYMMETRIC FUNCTIONS, RATIONAL FUNCTION

Symmetric Group

The symmetric group S_n of DEGREE n is the GROUP of all PERMUTATIONS on n symbols. S_n is therefore of ORDER $n!$ and contains as SUBGROUPS every GROUP of ORDER n. The number of CONJUGACY CLASSES of S_n is given by the PARTITION FUNCTION P.

NETTO'S CONJECTURE states that the probability that two elements P_1 and P_2 of a symmetric group generate the entire group tends to 3/4 as $n \to \infty$. This was proven by Dixon in 1967.

see also ALTERNATING GROUP, CONJUGACY CLASS, FINITE GROUP, NETTO'S CONJECTURE, PARTITION FUNCTION P, SIMPLE GROUP

References

Lomont, J. S. "Symmetric Groups." Ch. 7 in *Applications of Finite Groups.* New York: Dover, pp. 258–273, 1987.

Wilson, R. A. "ATLAS of Finite Group Representation." `http://for.mat.bham.ac.uk/atlas#alt`.

Symmetric Matrix

A symmetric matrix is a SQUARE MATRIX which satisfies $\mathsf{A}^{\mathrm{T}} = \mathsf{A}$ where A^{T} denotes the TRANSPOSE, so $a_{ij} = a_{ji}$. This also implies

$$\mathsf{A}^{-1}\mathsf{A}^{\mathrm{T}} = \mathsf{I}, \tag{1}$$

where I is the IDENTITY MATRIX. Written explicitly,

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}. \tag{2}$$

The symmetric part of any MATRIX may be obtained from

$$\mathsf{A}_s = \tfrac{1}{2}(\mathsf{A} + \mathsf{A}^{\mathrm{T}}). \tag{3}$$

A MATRIX A is symmetric if it can be expressed in the form

$$\mathsf{A} = \mathsf{QDQ}^{\mathrm{T}}, \tag{4}$$

where Q is an ORTHOGONAL MATRIX and D is a DIAGONAL MATRIX. This is equivalent to the MATRIX equation

$$\mathsf{AQ} = \mathsf{QD}, \tag{5}$$

which is equivalent to

$$\mathsf{A}\mathbf{Q}_n = \lambda_n \mathbf{Q}_n \tag{6}$$

for all n, where $\lambda_n = D_{nn}$. Therefore, the diagonal elements of D are the EIGENVALUES of A, and the columns of Q are the corresponding EIGENVECTORS.

see also ANTISYMMETRIC MATRIX, SKEW SYMMETRIC MATRIX

References

Nash, J. C. "Real Symmetric Matrices." Ch. 10 in *Compact Numerical Methods for Computers: Linear Algebra and Function Minimisation, 2nd ed.* Bristol, England: Adam Hilger, pp. 119–134, 1990.

Symmetric Points

Two points z and $z^S \in \mathbb{C}^*$ are symmetric with respect to a CIRCLE or straight LINE L if all CIRCLES and straight LINES passing through z and z^S are orthogonal to L. MÖBIUS TRANSFORMATIONS preserve symmetry. Let a straight line be given by a point z_0 and a unit VECTOR $e^{i\theta}$, then

$$z^S = e^{2i\theta}(z - z_0)^* + z_0.$$

Let a CIRCLE be given by center z_0 and RADIUS r, then

$$z^S = z_0 + \frac{r^2}{(z - z_0)^*}.$$

see also MÖBIUS TRANSFORMATION

Symmetric Relation

A RELATION R on a SET S is symmetric provided that for every x and y in S we have xRy IFF yRx.

see also RELATION

Symmetric Tensor

A second-RANK symmetric TENSOR is defined as a TENSOR A for which

$$A^{mn} = A^{nm}. \tag{1}$$

Any TENSOR can be written as a sum of symmetric and ANTISYMMETRIC parts

$$\begin{aligned} A^{mn} &= \tfrac{1}{2}(A^{mn} + A^{nm}) + \tfrac{1}{2}(A^{mn} - A^{nm}) \\ &= \tfrac{1}{2}({B_S}^{mn} + {B_A}^{mn}). \end{aligned} \tag{2}$$

The symmetric part of a TENSOR is denoted by parentheses as follows:

$$T_{(a,b)} \equiv \tfrac{1}{2}(T_{ab} + T_{ba}) \tag{3}$$

$$T_{(a_1,a_2,\ldots,a_n)} \equiv \frac{1}{n!} \sum_{\text{permutations}} T_{a_1a_2\cdots a_n}. \tag{4}$$

The product of a symmetric and an ANTISYMMETRIC TENSOR is 0. This can be seen as follows. Let $a^{\alpha\beta}$ be ANTISYMMETRIC, so

$$a^{11} = a^{22} = 0 \tag{5}$$

$$a^{21} = -a^{12}. \tag{6}$$

Let $b_{\alpha\beta}$ be symmetric, so

$$b_{12} = b_{21}. \tag{7}$$

Then

$$\begin{aligned} a^{\alpha\beta}b_{\alpha\beta} &= a^{11}b_{11} + a^{12}b_{12} + a^{21}b_{21} + a^{22}b_{22} \\ &= 0 + a^{12}b_{12} - a^{12}b_{12} + 0 = 0. \end{aligned} \tag{8}$$

A symmetric second-RANK TENSOR A_{mn} has SCALAR invariants

$$s_1 = A_{11} + A_{22} + A_{22} \tag{9}$$

$$\begin{aligned} s_2 = A_{22}A_{33} + A_{33}A_{11} + A_{11}A_{22} - {A_{23}}^2 \\ - {A_{31}}^2 - {A_{12}}^2. \end{aligned} \tag{10}$$

Symmetroid

A QUARTIC SURFACE which is the locus of zeros of the DETERMINANT of a SYMMETRIC 4 × 4 matrix of linear forms. A general symmetroid has 10 ORDINARY DOUBLE POINTS (Jessop 1916, Hunt 1996).

References

Hunt, B. "Algebraic Surfaces." `http://www.mathematik.uni-kl.de/~wwwagag/Galerie.html`.

Symmetry

An intrinsic property of a mathematical object which causes it to remain invariant under certain classes of transformations (such as ROTATION, REFLECTION, INVERSION, or more abstract operations). The mathematical study of symmetry is systematized and formalized in the extremely powerful and beautiful AREA of mathematics called GROUP THEORY.

Symmetry can be present in the form of coefficients of equations as well as in the physical arrangement of objects. By classifying the symmetry of polynomial equations using the machinery of GROUP THEORY, for example, it is possible to prove the unsolvability of the general QUINTIC EQUATION.

In physics, an extremely powerful theorem of Noether states that each symmetry of a system leads to a physically conserved quantity. Symmetry under TRANSLATION corresponds to momentum conservation, symmetry under ROTATION to angular momentum conservation, symmetry in time to energy conservation, etc.

see also GROUP THEORY

Symmetry Group

see GROUP

Symmetry Operation

Symmetry operations include the IMPROPER ROTATION, INVERSION OPERATION, MIRROR PLANE, and ROTATION. Together, these operations create 32 crystal classes corresponding to the 32 POINT GROUPS.

The INVERSION OPERATION takes

$$(x, y, z) \to (-x, -y, -z)$$

and is denoted i. When used in conjunction with a ROTATION, it becomes an IMPROPER ROTATION. An IMPROPER ROTATION by 360°$/n$ is denoted $\bar{n}$ (or S_n). For periodic crystals, the CRYSTALLOGRAPHY RESTRICTION allows only the IMPROPER ROTATIONS $\bar{1}$, $\bar{2}$, $\bar{3}$, $\bar{4}$, and $\bar{6}$.

The MIRROR PLANE symmetry operation takes

$$(x, y, z) \to (x, y, -z), (x, -y, z) \to (x, -y, z),$$

etc., which is equivalent to $\bar{2}$. Invariance under reflection can be denoted $n\sigma_v$ or $n\sigma_h$. The ROTATION symmetry operation for 360°$/n$ is denoted n (or C_n). For periodic crystals, CRYSTALLOGRAPHY RESTRICTION allows only 1, 2, 3, 4, and 6.

Symmetry operations can be indicated with symbols such as C_n, S_n, E, i, $n\sigma_v$, and $n\sigma_h$.

1. C_n indicates ROTATION about an n-fold symmetry axis.
2. S_n indicates IMPROPER ROTATION about an n-fold symmetry axis.
3. E (or I) indicates invariance under TRANSLATION.
4. i indicates a center of symmetry under INVERSION.

5. $n\sigma_v$ indicates invariance under n vertical REFLECTIONS.
6. $n\sigma_h$ indicates invariance under n horizontal REFLECTIONS.

see also CRYSTALLOGRAPHY RESTRICTION, IMPROPER ROTATION, INVERSION OPERATION, MIRROR PLANE, POINT GROUPS, ROTATION, SYMMETRY

Symmetry Principle

SYMMETRIC POINTS are preserved under a MÖBIUS TRANSFORMATION.

see also MÖBIUS TRANSFORMATION, SYMMETRIC POINTS

Symplectic Diffeomorphism

A MAP $T : (M_1, \omega_1) \to (M_2, \omega_2)$ between the SYMPLECTIC MANIFOLDS (M_1, ω_1) and (M_2, ω_2) which is a DIFFEOMORPHISM and $T^*(\omega_2) = \omega_1$ (where T^* is the PULLBACK MAP induced by T, i.e., the derivative of the DIFFEOMORPHISM T acting on tangent vectors). A symplectic diffeomorphism is also known as a SYMPLECTOMORPHISM or CANONICAL TRANSFORMATION.

see also DIFFEOMORPHISM, PULLBACK MAP, SYMPLECTIC MANIFOLD

References

Guillemin, V. and Sternberg, S. *Symplectic Techniques in Physics.* New York: Cambridge University Press, p. 34, 1984.

Symplectic Form

A symplectic form on a SMOOTH MANIFOLD M is a smooth closed 2-FORM ω on M which is nondegenerate such that at every point m, the alternating bilinear form ω_m on the TANGENT SPACE $T_m M$ is nondegenerate.

A symplectic form on a VECTOR SPACE V over F_q is a function $f(x, y)$ (defined for all $x, y \in V$ and taking values in F_q) which satisfies

$$f(\lambda_1 x_1 + \lambda_2 x_2, y) = \lambda_1 f(x_1, y) + \lambda_2 f(x_2, y),$$

$$f(y, x) = -f(x, y),$$

and

$$f(x, x) = 0.$$

Symplectic forms can exist on M (or V) only if M (or V) is EVEN-dimensional.

Symplectic Group

The symplectic group $Sp_n(q)$ for n EVEN is the GROUP of elements of the GENERAL LINEAR GROUP GL_n that preserve a given nonsingular SYMPLECTIC FORM. Any such MATRIX has DETERMINANT 1.

see also GENERAL LINEAR GROUP, LIE-TYPE GROUP, PROJECTIVE SYMPLECTIC GROUP, SYMPLECTIC FORM

References

Wilson, R. A. "ATLAS of Finite Group Representation." `http://for.mat.bham.ac.uk/atlas#symp`.

Symplectic Manifold

A pair (M, ω), where M is a MANIFOLD and ω is a SYMPLECTIC FORM on M. The PHASE SPACE $\mathbb{R}^{2n} = \mathbb{R}^n \times \mathbb{R}^n$ is a symplectic manifold. Near every point on a symplectic manifold, it is possible to find a set of local "Darboux coordinates" in which the SYMPLECTIC FORM has the simple form

$$\omega = \sum_k dq_k \wedge dp_k$$

(Sjamaar 1996), where $dq_k \wedge dp_k$ is a WEDGE PRODUCT.

see also MANIFOLD, SYMPLECTIC DIFFEOMORPHISM, SYMPLECTIC FORM

References

Symplectic Map

A MAP which preserves the sum of AREAS projected onto the set of (p_i, q_i) planes. It is the generalization of an AREA-PRESERVING MAP.

see also AREA-PRESERVING MAP, LIOUVILLE'S PHASE SPACE THEOREM

Symplectomorphism

see SYMPLECTIC DIFFEOMORPHISM

Synclastic

A surface on which the GAUSSIAN CURVATURE K is everywhere POSITIVE. When K is everywhere NEGATIVE, a surface is called ANTICLASTIC. A point at which the GAUSSIAN CURVATURE is POSITIVE is called an ELLIPTIC POINT.

see also ANTICLASTIC, ELLIPTIC POINT, GAUSSIAN QUADRATURE, HYPERBOLIC POINT, PARABOLIC POINT, PLANAR POINT

Synergetics

Synergetics deals with systems composed of many subsystems which may each be of a very different nature. In particular, synergetics treats systems in which cooperation among subsystems creates organized structure on macroscopic scales (Haken 1993). Examples of problems treated by synergetics include BIFURCATIONS, phase transitions in physics, convective instabilities, coherent oscillations in lasers, nonlinear oscillations in electrical circuits, population dynamics, etc.

System of Equations

Let a linear system of equations be denoted

$$\mathsf{A}\mathbf{X} = \mathbf{Y}, \qquad (1)$$

where A is a Matrix and $\mathbf{X}$ and $\mathbf{Y}$ are Vectors. As shown by Cramer's Rule, there is a unique solution if A has a Matrix Inverse A^{-1}. In this case,

$$\mathbf{X} = \mathsf{A}^{-1}\mathbf{Y}. \qquad (2)$$

If $\mathbf{Y} = \mathbf{0}$, then the solution is $\mathbf{X} = \mathbf{0}$. If A has no Matrix Inverse, then the solution Subspace is either a Line or the Empty Set. If two equations are multiples of each other, solutions are of the form

$$\mathbf{X} = \mathbf{A} + t\mathbf{B}, \qquad (3)$$

for t a Real Number.

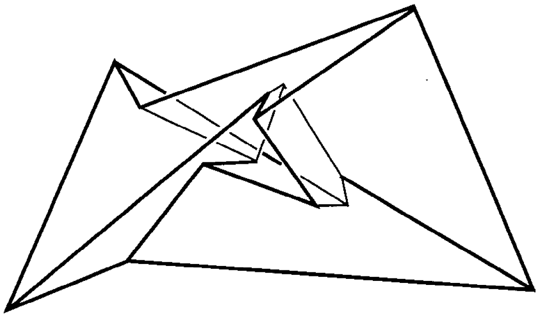
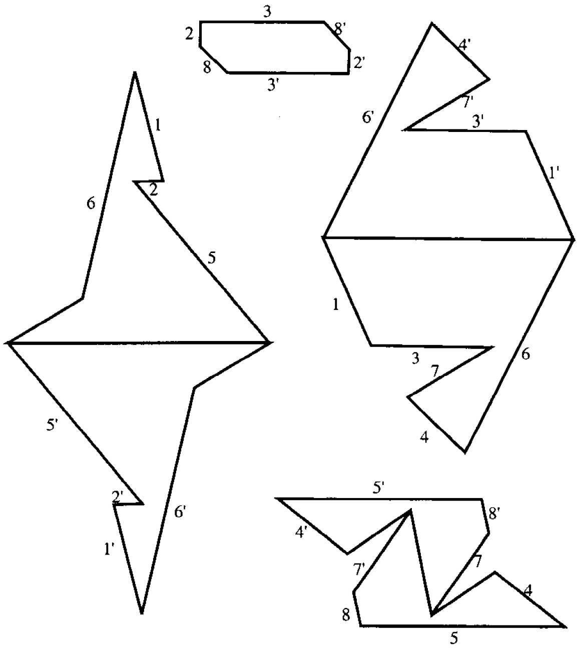
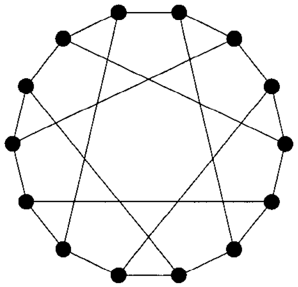
Szilassi Polyhedron





A Polyhedron which is topologically equivalent to a Torus and for which every pair of faces has an Edge in common. This polyhedron was discovered by L. Szilassi in 1977. Its Skeleton is equivalent to the seven-color torus map illustrated below.



The Szilassi polyhedron has 14 VERTICES, seven faces, and 21 EDGES, and is the DUAL POLYHEDRON of the CSÁSZÁR POLYHEDRON.

Tait Flyping Conjecture

see FLYPING CONJECTURE

Tait's Hamiltonian Graph Conjecture

Every 3-connected cubic Graph (each Vertex has Valency 3) has a Hamiltonian Circuit. Proposed by Tait in 1880 and refuted by W. T. Tutte in 1946 with a counterexample, Tutte's Graph. If it had been true, it would have implied the Four-Color Theorem. A simpler counterexample was later given by Kozyrev and Grinberg.

Tait's Knot Conjectures

P. G. Tait undertook a study of Knots in response to Kelvin's conjecture that the atoms were composed of knotted vortex tubes of ether (Thomson 1869). He categorized Knots in terms of the number of crossings in a plane projection. He also made some conjectures which remained unproven until the discovery of Jones Polynomials.

Tait's Flyping Conjecture states that the number of crossings is the same for any diagram of an Alternating Knot. This was proved true in 1986.

TAK Function

A Recursive Function devised by I. Takeuchi. For Integers x, y, and z, and a function h, it is

$$\mathrm{TAK}_h(x,y,z) = \begin{cases} h(x,y,z) & \text{for } x \leq y \\ h(h(x-1,y,z), h(y-1,z,x), & \text{for } x > y. \\ \quad h(z-1,x,y)) & \end{cases}$$

The number of function calls $F_0(a,b)$ required to compute $\mathrm{TAK}_0(a,b,0)$ for $a > b > 0$ is

$$F_0(a,b) = 4\sum_{k=0}^{b} \frac{a-b}{a+b-2k}\binom{a+b-2k}{b-k} - 3$$
$$= 1 + 4\sum_{k=0}^{b-1} \frac{a-b}{a+b-2k}\binom{a+b-2k}{b-k}$$

(Vardi 1991).

The TAK function is also connected with the Ballot Problem (Vardi 1991).

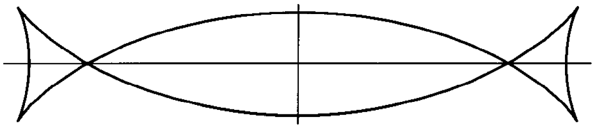
Talbot's Curve



A curve investigated by Talbot which is the Negative Pedal Curve of an Ellipse with respect to its center. It has four Cusps and two Nodes, provided the Eccentricity of the Ellipse is greater than $1/\sqrt{2}$. Its Cartesian Equation is

$$x = \frac{(a^2 + f^2 \sin^2 t)\cos t}{a}$$
$$y = \frac{(a^2 - 2f^2 + f^2 \sin^2 t)\sin t}{b},$$

where f is a constant.

Tame Algebra

Let A denote an $\mathbb{R}$-algebra, so that A is a VECTOR SPACE over R and

$$A \times A \to A$$

$$(x, y) \mapsto x \cdot y,$$

where $x \cdot y$ is vector multiplication which is assumed to be BILINEAR. Now define

$$Z \equiv \{x \in a : x \cdot y = 0 \text{ for some nonzero } y \in A\},$$

where $0 \in Z$. A is said to be tame if Z is a finite union of SUBSPACES of A. A 2-D 0-ASSOCIATIVE algebra is tame, but a 4-D 4-ASSOCIATIVE algebra and a 3-D 1-ASSOCIATIVE algebra need not be tame. It is conjectured that a 3-D 2-ASSOCIATIVE algebra is tame, and proven that a 3-D 3-ASSOCIATIVE algebra is tame if it possesses a multiplicative IDENTITY ELEMENT.

References
Finch, S. "Zero Structures in Real Algebras." `http://www.mathsoft.com/asolve/zerodiv/zerodiv.html`.

Tame Knot

A KNOT equivalent to a POLYGONAL KNOT. Knots which are not tame are called WILD KNOTS.

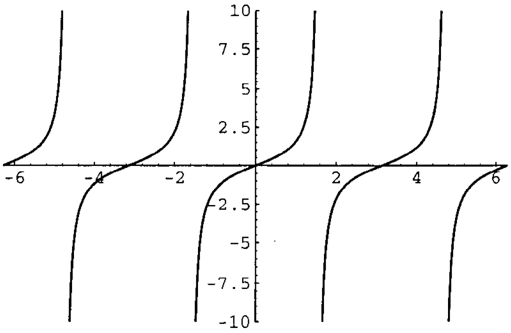
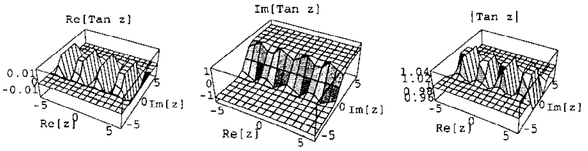
Tangency Theorem

The external (internal) SIMILARITY POINT of two fixed CIRCLES is the point at which all the CIRCLES homogeneously (nonhomogeneously) tangent to the fixed CIRCLES have the same POWER and at which all the tangency secants intersect.

References
Dörrie, H. *100 Great Problems of Elementary Mathematics: Their History and Solutions.* New York: Dover, p. 157, 1965.

Tangent





The tangent function is defined by

$$\tan\theta \equiv \frac{\sin\theta}{\cos\theta}, \tag{1}$$

where $\sin x$ is the SINE function and $\cos x$ is the COSINE function. The word "tangent," however, also has an important related meaning as a LINE or PLANE which touches a given curve or solid at a single point. These geometrical objects are then called a TANGENT LINE or TANGENT PLANE, respectively.

The MACLAURIN SERIES for the tangent function is

$$\tan x = \sum \frac{(-1)^{n-1}2^{2n}(2^{2n}-1)B_{2n}}{(2n)!}x^{2n-1} + \ldots$$
$$= x + \tfrac{1}{3}x^3 + \tfrac{2}{15}x^5 + \tfrac{17}{315}x^7 + \tfrac{62}{2835}x^9 + \ldots, \quad (2)$$

where B_n is a BERNOULLI NUMBER.

$\tan x$ is IRRATIONAL for any RATIONAL $x \neq 0$, which can be proved by writing $\tan x$ as a CONTINUED FRACTION

$$\tan x = \cfrac{x}{1 - \cfrac{x^2}{3 - \cfrac{x^2}{5 - \cfrac{x^2}{7 - \ldots}}}}. \quad (3)$$

Lambert derived another CONTINUED FRACTION expression for the tangent,

$$\tan x = \cfrac{1}{\frac{1}{x} - \cfrac{1}{\frac{3}{x} - \cfrac{1}{\frac{5}{x} - \cfrac{1}{\frac{7}{x} - \ldots}}}}. \quad (4)$$

An interesting identity involving the PRODUCT of tangents is

$$\prod_{k=1}^{\lfloor (n-1)/2 \rfloor} \tan\left(\frac{k\pi}{n}\right) = \begin{cases} \sqrt{n} & \text{for } n \text{ odd} \\ 1 & \text{for } n \text{ even,} \end{cases} \quad (5)$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION. Another tangent identity is

$$\tan(n \tan^{-1} x) = \frac{1}{i}\frac{(1+ix)^n - (1-ix)^n}{(1+ix)^n + (1-ix)^m} \quad (6)$$

(Beeler *et al.* 1972, Item 16).

Tangent Bifurcation

see FOLD BIFURCATION

Tangent Bundle

The tangent bundle TM of a SMOOTH MANIFOLD M is the SPACE of TANGENT VECTORS to points in the manifold, i.e., it is the set (x, v) where $x \in M$ and v is tangent to $x \in M$. For example, the tangent bundle to the CIRCLE is the CYLINDER.

see also COTANGENT BUNDLE, TANGENT VECTOR

Tangent Developable

A RULED SURFACE M is a tangent developable of a curve $\mathbf{y}$ if M can be parameterized by $\mathbf{x}(u,v) = \mathbf{y}(u) + v\mathbf{y}'(u)$. A tangent developable is a FLAT SURFACE.

Yates, R. C. "Instantaneous Center of Rotation and the Construction of Some Tangents." *A Handbook on Curves and Their Properties.* Ann Arbor, MI: J. W. Edwards, pp. 119–122, 1952.

Tangent Map

If $f : M \to N$, then the tangent map Tf associated to f is a VECTOR BUNDLE HOMEOMORPHISM $Tf : TM \to TN$ (i.e., a MAP between the TANGENT BUNDLES of M and N respectively). The tangent map corresponds to DIFFERENTIATION by the formula

$$Tf(v) = (f \circ \phi)'(0), \tag{1}$$

where $\phi'(0) = v$ (i.e., ϕ is a curve passing through the base point to v in TM at time 0 with velocity v). In this case, if $f : M \to N$ and $g : N \to O$, then the CHAIN RULE is expressed as

$$T(f \circ g) = Tf \circ Tg. \tag{2}$$

In other words, with this way of formalizing differentiation, the CHAIN RULE can be remembered by saying that "the process of taking the tangent map of a map is functorial." To a topologist, the form

$$(f \circ g)'(a) = f'(g(a)) \circ g'(a), \tag{3}$$

for all a, is more intuitive than the usual form of the CHAIN RULE.

see also DIFFEOMORPHISM

References
Gray, A. "Tangent Maps." §9.3 in *Modern Differential Geometry of Curves and Surfaces.* Boca Raton, FL: CRC Press, pp. 168–171, 1993.

Tangent Number

A number also called a ZAG NUMBER giving the number of EVEN ALTERNATING PERMUTATIONS. The first few are 1, 2, 16, 272, 7936, ... (Sloane's A000182).

see also ALTERNATING PERMUTATION, EULER ZIGZAG NUMBER, SECANT NUMBER

References
Knuth, D. E. and Buckholtz, T. J. "Computation of Tangent, Euler, and Bernoulli Numbers." *Math. Comput.* **21**, 663–688, 1967.
Sloane, N. J. A. Sequence A000182/M2096 in "An On-Line Version of the Encyclopedia of Integer Sequences."

Tangent Plane

A tangent plane is a PLANE which meets a given SURFACE at a single POINT. Let (x_0, y_0) be any point of a surface function $z = f(x, y)$. The surface has a nonvertical tangent plane at (x_0, y_0) with equation

$$z = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0).$$

see also NORMAL VECTOR, TANGENT, TANGENT LINE, TANGENT SPACE, TANGENT VECTOR

Tangent Space

Let x be a point in an n-dimensional COMPACT MANIFOLD M, and attach at x a copy of $\mathbb{R}^n$ tangential to M. The resulting structure is called the TANGENT SPACE of M at x and is denoted T_xM. If γ is a smooth curve passing through x, then the derivative of γ at x is a VECTOR in T_xM.

see also TANGENT, TANGENT BUNDLE, TANGENT PLANE, TANGENT VECTOR

Tangent Vector

For a curve with POSITION VECTOR $\mathbf{r}(t)$, the unit tangent vector $\hat{\mathbf{T}}(t)$ is defined by

$$\hat{\mathbf{T}}(t) \equiv \frac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \frac{\frac{d\mathbf{r}}{dt}}{\left|\frac{d\mathbf{r}}{dt}\right|} \tag{1}$$

$$= \frac{\frac{d\mathbf{r}}{dt}}{\frac{ds}{dt}} \tag{2}$$

$$= \frac{d\mathbf{r}}{ds}, \tag{3}$$

where t is a parameterization variable and s is the ARC LENGTH. For a function given parametrically by $(f(t), g(t))$, the tangent vector relative to the point $(f(t), g(t))$ is therefore given by

$$x(t) = \frac{f'}{\sqrt{f'^2 + g'^2}} \tag{4}$$

$$y(t) = \frac{g'}{\sqrt{f'^2 + g'^2}}. \tag{5}$$

To actually place the vector tangent to the curve, it must be displaced by $(f(t), g(t))$. It is also true that

$$\frac{d\hat{\mathbf{T}}}{ds} = \kappa\hat{\mathbf{N}} \tag{6}$$

$$\frac{d\hat{\mathbf{T}}}{dt} = \kappa\frac{ds}{dt}\hat{\mathbf{N}} \tag{7}$$

$$[\dot{\mathbf{T}}, \ddot{\mathbf{T}}, \dddot{\mathbf{T}}] = \kappa^5 \frac{d}{ds}\left(\frac{\tau}{\kappa}\right), \tag{8}$$

where $\mathbf{N}$ is the NORMAL VECTOR, κ is the CURVATURE, and τ is the TORSION.

see also CURVATURE, NORMAL VECTOR, TANGENT, TANGENT BUNDLE, TANGENT PLANE, TANGENT SPACE, TORSION (DIFFERENTIAL GEOMETRY)

References
Gray, A. "Tangent and Normal Lines to Plane Curves." §5.5 in *Modern Differential Geometry of Curves and Surfaces.* Boca Raton, FL: CRC Press, pp. 85–90, 1993.

Tangential Angle

For a PLANE CURVE, the tangential angle ϕ is defined by

$$\rho\, d\phi = ds, \tag{1}$$

where s is the ARC LENGTH and ρ is the RADIUS OF CURVATURE. The tangential angle is therefore given by

$$\phi = \int_0^t s'(t)\kappa(t)\, dt, \tag{2}$$

where $\kappa(t)$ is the CURVATURE. For a plane curve $\mathbf{r}(t)$, the tangential angle $\phi(t)$ can also be defined by

$$\frac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \begin{bmatrix} \cos[\phi(t)] \\ \sin[\phi(t)] \end{bmatrix}. \tag{3}$$

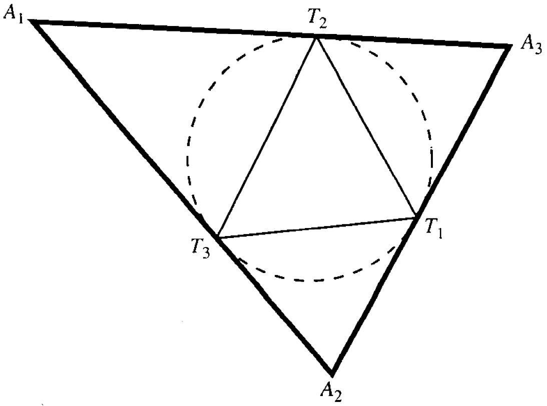
Gray (1993) calls ϕ the TURNING ANGLE instead of the tangential angle.

see also ARC LENGTH, CURVATURE, PLANE CURVE, RADIUS OF CURVATURE, TORSION (DIFFERENTIAL GEOMETRY)

References

Gray, A. "The Turning Angle." §1.6 in *Modern Differential Geometry of Curves and Surfaces.* Boca Raton, FL: CRC Press, pp. 13–14, 1993.

Tangential Triangle



The TRIANGLE $\Delta T_1T_2T_3$ formed by the lines tangent to the CIRCUMCIRCLE of a given TRIANGLE $\Delta A_1A_2A_3$ at its VERTICES. It is the PEDAL TRIANGLE of $\Delta A_1A_2A_3$ with the CIRCUMCENTER as the PEDAL POINT. The TRILINEAR COORDINATES of the VERTICES of the tangential triangle are

$$\begin{aligned} A' &= -a : b : c \\ B' &= a : -b : c \\ C' &= a : b : -c. \end{aligned}$$

The CONTACT TRIANGLE and tangential triangle are perspective from the GERGONNE POINT.

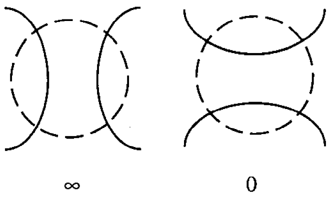
Tangents Law

see LAW OF TANGENTS

Tangle



A region in a KNOT or LINK projection plane surrounded by a CIRCLE such that the KNOT or LINK crosses the circle exactly four times. Two tangles are equivalent if a sequence of REIDEMEISTER MOVES can be used to transform one into the other while keeping the four string endpoints fixed and not allowing strings to pass outside the CIRCLE.

The simplest tangles are the ∞-tangle and 0-tangle, shown above. A tangle with n left-handed twists is called an n-tangle, and one with n right-handed twists is called a $-n$-tangle. By placing tangles side by side, more complicated tangles can be built up such as $(-2, 3, 2)$, etc. The link created by connecting the ends of the tangles is now described by the sequence of tangle symbols, known as CONWAY'S KNOT NOTATION. If tangles are multiplied by 0 and then added, the resulting tangle symbols are separated by commas. Additional symbols which are used are the period, colon, and asterisk.

Amazingly enough, two tangles described in this NOTATION are equivalent IFF the CONTINUED FRACTIONS of the form

$$2 + \cfrac{1}{3 + \cfrac{1}{-2}}$$

are equal (Burde and Zieschang 1985)! An ALGEBRAIC TANGLE is any tangle obtained by ADDITIONS and MULTIPLICATIONS of rational tangles (Adams 1994). Not all tangles are ALGEBRAIC.

Tanh

see HYPERBOLIC TANGENT

Taniyama Conjecture

see TANIYAMA-SHIMURA CONJECTURE

Taniyama-Shimura Conjecture

A conjecture which arose from several problems proposed by Taniyama in an international mathematics symposium in 1955. Let E be an ELLIPTIC CURVE whose equation has INTEGER COEFFICIENTS, let N be the CONDUCTOR of E and, for each n, let a_n be the number appearing in the L-function of E. Then there exists a MODULAR FORM of weight two and level N which is an eigenform under the HECKE OPERATORS and has a FOURIER SERIES $\sum a_n q^n$.

The conjecture says, in effect, that every rational ELLIPTIC CURVE is a MODULAR FORM in disguise. Stated formally, the conjecture suggests that, for every ELLIPTIC CURVE $y^2 = Ax^3 + Bx^2 + Cx + D$ over the RATIONALS, there exist nonconstant MODULAR FUNCTIONS $f(z)$ and $g(z)$ of the same level N such that

$$[f(z)]^2 = A[g(z)]^2 + Cg(z) + D.$$

Equivalently, for every ELLIPTIC CURVE, there is a MODULAR FORM with the same DIRICHLET L-SERIES.

In 1985, starting with a fictitious solution to FERMAT'S LAST THEOREM, G. Frey showed that he could create an unusual ELLIPTIC CURVE which appeared not to be modular. If the curve were not modular, then this would show that if FERMAT'S LAST THEOREM were false, then the Taniyama-Shimura conjecture would also be false. Furthermore, if the Taniyama-Shimura conjecture were true, then so would be FERMAT'S LAST THEOREM!

However, Frey did not actually prove whether his curve was modular. The conjecture that Frey's curve *was* modular came to be called the "epsilon conjecture," and was quickly proved by Ribet (RIBET'S THEOREM) in 1986, establishing a very close link between two mathematical structures (the Taniyama-Shimura conjecture and FERMAT'S LAST THEOREM) which appeared previously to be completely unrelated.

As of the early 1990s, most mathematicians believed that the Taniyama-Shimura conjecture was not accessible to proof. However, A. Wiles was not one of these. He attempted to establish the correspondence between the set of ELLIPTIC CURVES and the set of modular elliptic curves by showing that the number of each was the same. Wiles accomplished this by "counting" Galois representations and comparing them with the number of modular forms. In 1993, after a monumental seven-year effort, Wiles (almost) proved the Taniyama-Shimura conjecture for special classes of curves called SEMISTABLE ELLIPTIC CURVES.

Wiles had tried to use horizontal Iwasawa theory to create a so-called CLASS NUMBER formula, but was initially unsuccessful and therefore used instead an extension of a result of Flach based on ideas from Kolyvagin. However, there was a problem with this extension which was discovered during review of Wiles' manuscript in September 1993. Former student Richard Taylor came to Princeton in early 1994 to help Wiles patch up this error. After additional effort, Wiles discovered the reason that the Flach/Kolyvagin approach was failing, and also discovered that it was precisely what had prevented Iwasawa theory from working.

With this additional insight, he was able to successfully complete the erroneous portion of the proof using Iwasawa theory, proving the SEMISTABLE case of the Taniyama-Shimura conjecture (Taylor and Wiles 1995, Wiles 1995) and, at the same time, establishing FERMAT'S LAST THEOREM as a true theorem.

Tarry-Escott Problem

For each POSITIVE INTEGER l, there exists a POSITIVE INTEGER n and a PARTITION of $\{1, \ldots, n\}$ as a disjoint union of two sets A and B, such that for $1 \leq i \leq l$,

$$\sum_{a\in A} a^i = \sum_{b\in B} b^i.$$

The results extended to three or more sets of INTEGERS are called PROUHET'S PROBLEM.

Tarry Point

The point at which the lines through the VERTICES of a TRIANGLE PERPENDICULAR to the corresponding sides of the first BROCARD TRIANGLE, are CONCURRENT. The Tarry point lies on the CIRCUMCIRCLE opposite the STEINER POINT. It has TRIANGLE CENTER FUNCTION

$$\alpha = \frac{bc}{b^4 + c^4 - a^2b^2 - a^2c^2} = \sec(A + \omega),$$

where ω is the BROCARD ANGLE. The SIMSON LINE of the Tarry point is PERPENDICULAR to the line OK, when O is the CIRCUMCENTER and K is the LEMOINE POINT.

Tau Conjecture

Also known as RAMANUJAN'S HYPOTHESIS. Ramanujan proposed that

$$\tau(n) \sim \mathcal{O}(n^{11/2+\epsilon}),$$

where $\tau(n)$ is the TAU FUNCTION, defined by

$$\sum_{n=1}^{\infty} \tau(n)x^n = x(1 - 3x + 5x^3 - 7x^6 + \ldots)^8.$$

This was proven by Deligne (1974), who was subsequently awarded the FIELDS MEDAL for his proof.

Tau-Dirichlet Series

$$\tau_{DS}(s) \equiv \sum_{n=1}^{\infty} \frac{\tau(n)}{n^s},$$

where $\tau(n)$ is the TAU FUNCTION. Ramanujan conjectured that all nontrivial zeros of $f(z)$ lie on the line $\Re[s] = 6$, where

$$f(s) \equiv \sum_{n=1}^{\infty} \tau(n) n^{-z}$$

and $\tau(n)$ is the TAU FUNCTION.

Tau Function

A function $\tau(n)$ related to the DIVISOR FUNCTION $\sigma_k(n)$, also sometimes called RAMANUJAN'S TAU FUNCTION. It is given by the GENERATING FUNCTION

$$\sum_{n=1}^{\infty} \tau(n) x^n = \prod_{n=1}^{\infty} (1 - x^n)^{24}, \tag{1}$$

and the first few values are 1, −24, 252, −1472, 4380, ... (Sloane's A000594). $\tau(n)$ is also given by

$$g(-x) = \sum_{n=1}^{\infty} (-1)^n \tau(n) x^n \tag{2}$$

$$g(x^2) = \sum_{n=1}^{\infty} \tau(\tfrac{1}{2}n) x^n \tag{3}$$

$$\sum_{n=1}^{\infty} \tau(n) x^n = x(1 - 3x + 5x^3 - 7x^6 + \ldots)^8. \tag{4}$$

In ORE'S CONJECTURE, the tau function appears as the number of DIVISORS of n. Ramanujan conjectured and Mordell proved that if (n, n'), then

$$\tau(nn') = \tau(n)\tau(n'). \tag{5}$$

Ramanujan conjectured and Watson proved that $\tau(n)$ is divisible by 691 for almost all n. If

$$\tau(p) \equiv 0 \pmod{p}, \tag{6}$$

then

$$\tau(pn) \equiv 0 \pmod{p}. \tag{7}$$

Values of p for which the first equation holds are $p = 2$, 3, 5, 7, 23.

Ramanujan also studied

$$f(x) \equiv \sum_{n=1}^{\infty} \tau(n) n^{-s}, \tag{8}$$

which has properties analogous to the RIEMANN ZETA FUNCTION. It satisfies

$$\frac{f(s)\Gamma(s)}{(2\pi)^s} = \frac{f(12-s)}{(2\pi)^{12-s}}, \tag{9}$$

and Ramanujan's TAU-DIRICHLET SERIES conjecture alleges that all nontrivial zeros of $f(s)$ lie on the line $\Re[s] = 6$. f can be split up into

$$f(6 + it) = z(t) e^{-i\theta(t)}, \tag{10}$$

where

$$z(t) = \Gamma(6 + it) f(6 + it) (2\pi)^{-it} \times \sqrt{\frac{\sinh(\pi t)}{\pi t(1 + t^2)(4 + t^2)(9 + t^2)(16 + t^2)(25 + t^2)}} \tag{11}$$

$$\theta(t) = -\tfrac{1}{2} i \ln \left[\frac{\Gamma(6 + it)}{\Gamma(6 - it)}\right] - t \ln(2\pi). \tag{12}$$

The SUMMATORY tau function is given by

$$T(n) = \sum_{n \leq x}{}' \tau(n). \tag{13}$$

Here, the prime indicates that when x is an INTEGER, the last term $\tau(x)$ should be replaced by $\frac{1}{2}\tau(x)$.

Ramanujan's tau theta function $Z(t)$ is a REAL function for REAL t and is analogous to the RIEMANN-SIEGEL FUNCTION Z. The number of zeros in the critical strip from $t = 0$ to T is given by

$$N(t) = \frac{\Theta(T) + \Im\{\ln[\tau_{DS}(6 + iT)]\}}{\pi}, \tag{14}$$

where Θ is the RIEMANN THETA FUNCTION and τ_{DS} is the TAU-DIRICHLET SERIES, defined by

$$\tau_{DS}(s) \equiv \sum_{n=1}^{\infty} \frac{\tau(n)}{n^s}. \tag{15}$$

Ramanujan conjectured that the nontrivial zeros of the function are all real.

Ramanujan's τ_z function is defined by

$$\tau_z(t) = \frac{\Gamma(6+it)(2\pi)^{-it}}{\tau_{DS}(6+it)\sqrt{\frac{\sinh(\pi t)}{\pi t \prod_{k=1}^{5} k^2+t^2}}}, \tag{16}$$

where $\tau_{DS}(z)$ is the Tau-Dirichlet Series.

Tauberian Theorem

A Tauberian theorem is a theorem which deduces the convergence of an Infinite Series on the basis of the properties of the function it defines and any kind of auxiliary Hypothesis which prevents the general term of the series from converging to zero too slowly.

see also Hardy-Littlewood Tauberian Theorem

Tautochrone Problem

Find the curve down which a bead placed anywhere will fall to the bottom in the same amount of time. The solution is a Cycloid, a fact first discovered and published by Huygens in *Horologium oscillatorium* (1673). Huygens also constructed the first pendulum clock with a device to ensure that the pendulum was isochronous by forcing the pendulum to swing in an arc of a Cycloid.

The parametric equations of the Cycloid are

$$x = a(\theta - \sin\theta) \tag{1}$$

$$y = a(1 - \cos\theta). \tag{2}$$

To see that the Cycloid satisfies the tautochrone property, consider the derivatives

$$x' = a(1 - \cos\theta) \tag{3}$$

$$y' = a\sin\theta, \tag{4}$$

and

$$\begin{aligned} x'^2 + y'^2 &= a^2[(1 - 2\cos\theta + \cos^2\theta) + \sin^2\theta] \\ &= 2a^2(1 - \cos\theta). \end{aligned} \tag{5}$$

Now

$$\tfrac{1}{2}mv^2 = mgy \tag{6}$$

$$v = \frac{ds}{dt} = \sqrt{2gy} \tag{7}$$

$$\begin{aligned} dt = \frac{ds}{\sqrt{2gy}} &= \frac{\sqrt{dx^2 + dy^2}}{\sqrt{2gy}} \\ &= \frac{a\sqrt{2(1-\cos\theta)}\,d\theta}{\sqrt{2ga(1-\cos\theta)}} = \sqrt{\frac{a}{g}}\,d\theta, \end{aligned} \tag{8}$$

so the time required to travel from the top of the Cycloid to the bottom is

$$T = \int_0^\pi dt = \sqrt{\frac{a}{g}}\,\pi. \tag{9}$$

However, from an intermediate point θ_0,

$$v = \frac{ds}{dt} = \sqrt{2g(y - y_0)}, \tag{10}$$

so

$$\begin{aligned} T &= \int_{\theta_0}^{\pi} \frac{\sqrt{2a^2(1-\cos\theta)}}{2ag(\cos\theta_0 - \cos\theta)}\,d\theta \\ &= \sqrt{\frac{a}{g}} \int_{\theta_0}^{\pi} \sqrt{\frac{1-\cos\theta}{\cos\theta_0 - \cos\theta}}\,d\theta \\ &= \sqrt{\frac{a}{g}} \int_{\theta_0}^{\pi} \frac{\sin(\frac{1}{2}\theta)\,d\theta}{\sqrt{\cos^2(\frac{1}{2}\theta_0) - \cos^2(\frac{1}{2}\theta)}}. \end{aligned} \tag{11}$$

Now let

$$u = \frac{\cos(\frac{1}{2}\theta)}{\cos(\frac{1}{2}\theta_0)} \tag{12}$$

$$du = -\frac{\sin(\frac{1}{2}\theta)d\theta}{2\cos(\theta_0)}, \tag{13}$$

so

$$T = -2\sqrt{\frac{a}{g}} \int_1^0 \frac{du}{\sqrt{1-u^2}} = 2\sqrt{\frac{a}{g}}\,[\sin^{-1} u]_0^1 = \pi\sqrt{\frac{a}{g}}, \tag{14}$$

and the amount of time is the same from any point!

Tautology

A logical statement in which the conclusion is equivalent to the premise. If p is a tautology, it is written $\models p$.

Taxicab Number

The nth taxicab number $\mathrm{Ta}(n)$ is the smallest number representable in n ways as a sum of POSITIVE CUBES. The numbers derive their name from the HARDY-RAMANUJAN NUMBER

$$\begin{aligned}\mathrm{Ta}(2) &= 1729 \\ &= 1^3 + 12^3 \\ &= 9^3 + 10^3,\end{aligned} \tag{1}$$

which is associated with the following story told about Ramanujan by G. H. Hardy. "Once, in the taxi from London, Hardy noticed its number, 1729. He must have thought about it a little because he entered the room where Ramanujan lay in bed and, with scarcely a hello, blurted out his disappointment with it. It was, he declared, 'rather a dull number,' adding that he hoped that wasn't a bad omen. 'No, Hardy,' said Ramanujan, 'it is a very interesting number. It is the smallest number expressible as the sum of two [POSITIVE] cubes in two different ways'" (Hofstadter 1989, Kanigel 1991, Snow 1993).

However, this property was also known as early as 1657 by F. de Bessy (Berndt and Bhargava 1993, Guy 1994). Leech (1957) found

$$\begin{aligned}\mathrm{Ta}(3) &= 87539319 \\ &= 167^3 + 436^3 \\ &= 228^3 + 423^3 \\ &= 255^3 + 414^3.\end{aligned} \tag{2}$$

Rosenstiel *et al.* (1991) recently found

$$\begin{aligned}\mathrm{Ta}(4) &= 6963472309248 \\ &= 2421^3 + 19083^3 \\ &= 5436^3 + 18948^3 \\ &= 10200^3 + 18072^3 \\ &= 13322^3 + 16630^3.\end{aligned} \tag{3}$$

D. Wilson found

$$\begin{aligned}\mathrm{Ta}(5) &= 48988659276962496 \\ &= 38787^3 + 365757^3 \\ &= 107839^3 + 362753^3 \\ &= 205292^3 + 342952^3 \\ &= 221424^3 + 336588^3 \\ &= 231518^3 + 331954^3.\end{aligned} \tag{4}$$

The first few taxicab numbers are therefore 2, 1729, 87539319, 6963472309248, ... (Sloane's A011541).

Hardy and Wright (Theorem 412, 1979) show that the number of such sums can be made arbitrarily large but, updating Guy (1994) with Wilson's result, the least example is not known for six or more equal sums.

Sloane defines a slightly different type of taxicab numbers, namely numbers which are sums of two cubes in two or more ways, the first few of which are 1729, 4104, 13832, 20683, 32832, 39312, 40033, 46683, 64232, ... (Sloane's A001235).

Taylor Expansion

see TAYLOR SERIES

Taylor-Greene-Chirikov Map

see STANDARD MAP

Taylor Polynomial

see TAYLOR SERIES

Taylor Series

A Taylor series is a series expansion of a FUNCTION about a point. A 1-D Taylor series is an expansion of a SCALAR FUNCTION $f(x)$ about a point $x = a$. If $a = 0$, the expansion is known as a MACLAURIN SERIES.

$$\int_a^x f^{(n)}(x)\,dx = [f^{(n-1)}(x)]_a^x = f^{(n-1)}(x) - f^{(n-1)}(a) \tag{1}$$

$$\int_a^x \left[\int_a^x f^{(n)}(x)\,dx\right] dx = \int_a^x [f^{(n-1)}(x) - f^{(n-1)}(a)]\,dx$$
$$= f^{(n-2)}(x) - f^{(n-2)}(a) - (x-a)f^{(n-1)}(a). \tag{2}$$

Continuing,

$$\iiint_a^x f^{(n)}(x)\,(dx)^3 = f^{(n-3)}(a) - (x-a)f^{(n-2)}(a)$$
$$-\tfrac{1}{2!}(x-a)^2 f^{(n-1)}(a) \tag{3}$$

$$\underbrace{\int\cdots\int_a^x}_{n} f^{(n)}(x)\,(dx)^n = f(x) - f(a) - (x-a)f'(a)$$
$$-\tfrac{1}{2!}(x-a)^2 f''(a) - \ldots - \tfrac{1}{(n-1)!}(x-a)^{n-1} f^{(n-1)}(a). \tag{4}$$

Therefore, we obtain the 1-D Taylor series

$$f(x) = f(a) + (x-a)f'(a) + \tfrac{1}{2!}(x-a)^2 f''(a) + \ldots$$
$$+ \tfrac{1}{(n-1)!}(x-a)^{n-1} f^{(n-1)}(a) + R_n, \tag{5}$$

where R_n is a remainder term defined by

$$R_n = \underbrace{\int\cdots\int_a^x}_{n} f^{(n)}(x)\,(dx)^n. \tag{6}$$

Using the MEAN-VALUE THEOREM for a function g, it must be true that

$$\int_a^x g(x)\,dx = (x-a)g(x^*) \tag{7}$$

for some $x^* \in [a, x]$. Therefore, integrating n times gives the result

$$R_n = \frac{(x-a)^n}{n!} f^{(n)}(x). \tag{8}$$

The maximum error is then the maximum value of (8) for all possible $x^* \in [a, x]$.

An alternative form of the 1-D Taylor series may be obtained by letting

$$x - a \equiv \Delta x \tag{9}$$

so that

$$x = a + \Delta x \equiv x_0 + \Delta x. \tag{10}$$

Substitute this result into (5) to give

$$f(x_0 + \Delta x) = f(x_0) + \Delta x f'(x_0) + \tfrac{1}{2!}(\Delta x)^2 f''(x_0) + \ldots. \tag{11}$$

A Taylor series of a FUNCTION in two variables $f(x, y)$ is given by

$$f(x+\Delta x, y+\Delta y) = f(x,y) + [f_x(x,y)\Delta x + f_y(x,y)\Delta y]$$
$$+\tfrac{1}{2!}[(\Delta x)^2 f_{xx}(x,y) + 2\Delta x\Delta y f_{xy}(x,y) + (\Delta y)^2 f_{yy}(x,y)]$$
$$+\tfrac{1}{3!}[(\Delta x)^3 f_{xxx}(x,y) + 3(\Delta x)^2\Delta y f_{xxy}(x,y)$$
$$+3\Delta x(\Delta y)^2 f_{xyy}(x,y) + (\Delta y)^3 f_{yyy}(x,y)] + \ldots. \tag{12}$$

This can be further generalized for a FUNCTION in n variables,

$$f(x_1, \ldots, x_n)$$
$$= \sum_{j=0}^{\infty} \left\{ \frac{1}{j!} \left[\sum_{k=1}^{n} (x'_k - a_k) \frac{\partial}{\partial x'_k} \right]^j f(x'_1, \ldots, x'_n) \right\}_{x'_1=a_1,\ldots,x'_n=a_n}. \tag{13}$$

Rewriting,

$$f(x_1+a_1,\dots,x_n+a_n) = \sum_{j=0}^{\infty}\left\{\frac{1}{j!}\left(\sum_{k=1}^{n} a_k \frac{\partial}{\partial x'_k}\right)^j f(x'_1,\dots,x'_n)\right\}_{x'_1=x_1,\dots,x'_n=x_n}. \tag{14}$$

Taking $n=2$ in (13) gives

$$\begin{aligned} f(x_1,x_2) &= \sum_{j=0}^{\infty}\left\{\frac{1}{j!}\left[(x'_1-a_1)\frac{\partial}{\partial x'_1} + (x'_2-a_2)\frac{\partial}{\partial x'_2}\right]^j f(x'_1,x'_2)\right\}_{x'_1=x_1,x'_2=x_2} \\ &= f(a_1,a_2) + \left[(x_1-a_1)\frac{\partial f}{\partial x_1} + (x_2-a_2)\frac{\partial f}{\partial x_2}\right] \\ &\quad + \frac{1}{2!}\left[(x_1-a_1)^2\frac{\partial^2 f}{\partial {x_1}^2} + 2(x_1-a_1)(x_2-a_2)\frac{\partial^2 f}{\partial x_1 \partial x_2} + (x_2-a_2)^2\frac{\partial^2 f}{\partial {x_2}^2}\right] + \dots \end{aligned} \tag{15}$$

Taking $n=3$ in (14) gives

$$\begin{aligned} f(x_1+a_1,x_2+a_2,x_3+a_3) &= \sum_{j=0}^{\infty}\left\{\frac{1}{j!}\left(a_1\frac{\partial}{\partial x'_1} + a_2\frac{\partial}{\partial x'_2} + a_3\frac{\partial}{\partial x'_3}\right)^j \right. \\ &\quad \left. \times f(x'_1,x'_2,x'_3)\right\}_{x'_1=x_1,x'_2=x_2,x'_3=x_3}, \end{aligned} \tag{16}$$

or, in VECTOR form

$$f(\mathbf{r}+\mathbf{a}) = \sum_{j=0}^{\infty}\left[\frac{1}{j!}(\mathbf{a}\cdot\nabla_{\mathbf{r}'})^j f(\mathbf{r}')\right]_{\mathbf{r}'=\mathbf{r}}. \tag{17}$$

The zeroth- and first-order terms are

$$f(\mathbf{r}) \tag{18}$$

and

$$(\mathbf{a}\cdot\nabla_{\mathbf{r}'})f(\mathbf{r}')|_{\mathbf{r}'=\mathbf{r}}, \tag{19}$$

respectively. The second-order term is

$$\begin{aligned} \tfrac{1}{2}(\mathbf{a}\cdot\nabla_{\mathbf{r}'})(\mathbf{a}\cdot\nabla_{\mathbf{r}'})f(\mathbf{r}')|_{\mathbf{r}'=\mathbf{r}} &= \tfrac{1}{2}\mathbf{a}\cdot\nabla_{\mathbf{r}'}[\mathbf{a}\cdot(\nabla f(\mathbf{r}'))]_{\mathbf{r}'=\mathbf{r}} \\ &= \tfrac{1}{2}\mathbf{a}\cdot[\mathbf{a}\cdot\nabla_{\mathbf{r}'}(\nabla_{\mathbf{r}'} f(\mathbf{r}'))]|_{\mathbf{r}'=\mathbf{r}}, \end{aligned} \tag{20}$$

so the first few terms of the expansion are

$$\begin{aligned} f(\mathbf{r}+\mathbf{a}) &= f(\mathbf{r}) + (\mathbf{a}\cdot\nabla_{\mathbf{r}'})f(\mathbf{r}')|_{\mathbf{r}'=\mathbf{r}} \\ &\quad + \tfrac{1}{2}\mathbf{a}\cdot[\mathbf{a}\cdot\nabla_{\mathbf{r}'}(\nabla_{\mathbf{r}'} f(\mathbf{r}'))]|_{\mathbf{r}'=\mathbf{r}}. \end{aligned} \tag{21}$$

Taylor series can also be defined for functions of a COMPLEX variable. By the CAUCHY INTEGRAL FORMULA,

$$\begin{aligned} f(z) &= \frac{1}{2\pi i}\int_C \frac{f(z')\,dz}{z'-z} = \frac{1}{2\pi i}\int_C \frac{f(z')\,dz'}{(z'-z_0)-(z-z_0)} \\ &= \frac{1}{2\pi i}\int_C \frac{f(z')\,dz'}{(z'-z_0)\left(1-\frac{z-z_0}{z'-z_0}\right)}. \end{aligned} \tag{22}$$

In the interior of C,

$$\frac{|z-z_0|}{|z'-z_0|} < 1 \tag{23}$$

so, using

$$\frac{1}{1-t} = \sum_{n=0}^{\infty} t^n, \tag{24}$$

it follows that

$$\begin{aligned} f(z) &= \frac{1}{2\pi i}\int_C \sum_{n=0}^{\infty}\frac{(z-z_0)^n f(z')\,dz'}{(z'-z_0)^{n+1}} \\ &= \frac{1}{2\pi i}\sum_{n=0}^{\infty}(z-z_0)^n \int_C \frac{f(z')\,dz}{(z'-z_0)^{n+1}}. \end{aligned} \tag{25}$$

Using the the CAUCHY INTEGRAL FORMULA for derivatives,

$$f(z) = \sum_{n=0}^{\infty}(z-z_0)^n \frac{f^{(n)}(z_0)}{n!}. \tag{26}$$

von Seggern, D. *CRC Standard Curves and Surfaces.* Boca Raton, FL: CRC Press, p. 174, 1993.

Technique

A specific method of performing an operation. The terms ALGORITHM, METHOD, and PROCEDURE are also used interchangeably.

see also ALGORITHM, METHOD, PROCEDURE

Teichmüller Space

TEICHMÜLLER'S THEOREM asserts the EXISTENCE and UNIQUENESS of the extremal quasiconformal map between two compact RIEMANN SURFACES of the same GENUS modulo an EQUIVALENCE RELATION. The equivalence classes form the Teichmüller space T_p of compact RIEMANN SURFACES of GENUS p.

see also RIEMANN'S MODULI PROBLEM

Teichmüller's Theorem

Asserts the EXISTENCE and UNIQUENESS of the extremal quasiconformal map between two compact RIEMANN SURFACES of the same GENUS modulo an EQUIVALENCE RELATION.

see also TEICHMÜLLER SPACE

Telescoping Sum

A sum in which subsequent terms cancel each other, leaving only initial and final terms. For example,

$$\begin{aligned} S &= \sum_{i=1}^{n-1}\left(\frac{1}{a_i} - \frac{1}{a_{i+1}}\right) \\ &= \left(\frac{1}{a_1} - \frac{1}{a_2}\right) + \left(\frac{1}{a_2} - \frac{1}{a_3}\right) + \ldots \\ &\quad + \left(\frac{1}{a_{n-2}} - \frac{1}{a_{n-1}}\right) + \left(\frac{1}{a_{n-1}} - \frac{1}{a_n}\right) \\ &= \frac{1}{a_1} - \frac{1}{a_n} \end{aligned}$$

is a telescoping sum.

see also ZEILBERGER'S ALGORITHM

Temperature

The "temperature" of a curve Γ is defined as

$$T \equiv \frac{1}{\ln\left(\frac{2l}{2l-h}\right)},$$

where l is the length of Γ and h is the length of the PERIMETER of the CONVEX HULL. The temperature of a curve is 0 only if the curve is a straight line, and increases as the curve becomes more "wiggly."

Tensor

An nth-RANK tensor of order m is a mathematical object in m-dimensional space which has n indices and m^n components and obeys certain transformation rules. Each index of a tensor ranges over the number of dimensions of SPACE. If the components of any tensor of any RANK vanish in one particular coordinate system, they vanish in all coordinate systems.

Zeroth-RANK tensors are called SCALARS, and first-RANK tensors are called VECTORS. In tensor notation, a vector $\mathbf{v}$ would be written v_i, where $i = 1, \ldots, m$. Tensor notation can provide a very concise way of writing vector and more general identities. For example, in tensor notation, the DOT PRODUCT $\mathbf{u} \cdot \mathbf{v}$ is simply written

$$\mathbf{u} \cdot \mathbf{v} = u_i v_i, \tag{1}$$

where repeated indices are summed over (EINSTEIN SUMMATION) so that $u_i v_i$ stands for $u_1 v_1 + \ldots + u_m v_m$. Similarly, the CROSS PRODUCT can be concisely written as

$$\mathbf{u} \times \mathbf{v} = \epsilon_{ijk} u^j v^k, \tag{2}$$

where ϵ_{ijk} is the LEVI-CIVITA TENSOR.

Second-RANK tensors resemble square MATRICES. CONTRAVARIANT second-RANK tensors are objects which transform as

$$A'^{ij} = \frac{\partial x'_i}{\partial x_k} \frac{\partial x'_j}{\partial x_l} A^{kl}. \tag{3}$$

COVARIANT second-RANK tensors are objects which transform as

$$C'_{ij} = \frac{\partial x_k}{\partial x'_i} \frac{\partial x_l}{\partial x'_i} C_{kl}. \tag{4}$$

MIXED second-RANK tensors are objects which transform as

$$B'^{j}_{i} = \frac{\partial x'_i}{\partial x_k} \frac{\partial x_l}{\partial x'_j} B^k_l. \tag{5}$$

If two tensors A and B have the same RANK and the same COVARIANT and CONTRAVARIANT indices, then

$$A^{ij} + B^{ij} = C^{ij} \tag{6}$$

$$A_{ij} + B_{ij} = C_{ij} \tag{7}$$

$$A^i_j + B^i_j = C^i_j. \tag{8}$$

A transformation of the variables of a tensor changes the tensor into another whose components are linear HOMOGENEOUS FUNCTIONS of the components of the original tensor.

Terminal

see SINK (DIRECTED GRAPH)

Ternary

The BASE 3 method of counting in which only the digits 0, 1, and 2 are used. These digits have the following multiplication table.

×	0	1	2
0	0	0	0
1	0	1	2
2	0	2	11

Erdős and Graham (1980) conjectured that no POWER of 2, 2^n, is a SUM of distinct powers of 3 for $n > 8$. This is equivalent to the requirement that the ternary expansion of 2^n always contains a 2. This has been verified by Vardi (1991) up to $n = 2 \cdot 3^{20}$. N. J. A. Sloane has conjectured that any POWER of 2 has a 0 in its ternary expansion (Vardi 1991, p. 28).

Tessellation

A regular TILING of POLYGONS (in 2-D), POLYHEDRA (3-D), or POLYTOPES (n-D) is called a tessellation. Tessellations can be specified using a SCHLÄFLI SYMBOL.

Consider a 2-D tessellation with q regular p-gons at each VERTEX. In the PLANE,

$$\left(1 - \frac{2}{p}\right)\pi = \frac{2\pi}{q} \tag{1}$$

$$\frac{1}{p} + \frac{1}{q} = \frac{1}{2}, \tag{2}$$

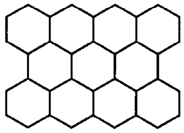
so

$$(p-2)(q-2) = 4 \tag{3}$$

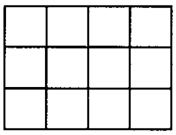
(Ball and Coxeter 1987), and the only factorizations are

$$\begin{aligned} 4 &= 4 \cdot 1 = (6-2)(3-2) \Rightarrow \{6,3\} && (4)\\ &= 2 \cdot 2 = (4-2)(4-2) \Rightarrow \{4,4\} && (5)\\ &= 1 \cdot 4 = (3-2)(6-2) \Rightarrow \{3,6\}. && (6) \end{aligned}$$

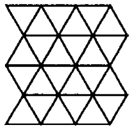
Therefore, there are only three regular tessellations (composed of the HEXAGON, SQUARE, and TRIANGLE), illustrated as follows.



$\{6,3\}$



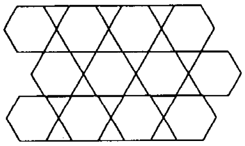
$\{4,4\}$

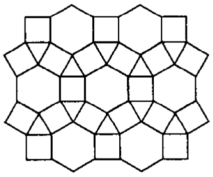


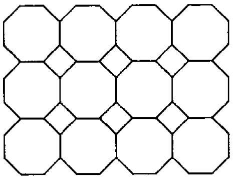
$\{3,6\}$

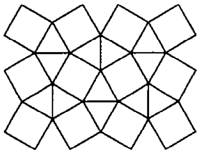
There do not exist any regular STAR POLYGON tessellations in the PLANE. Regular tessellations of the SPHERE by SPHERICAL TRIANGLES are called TRIANGULAR SYMMETRY GROUPS.

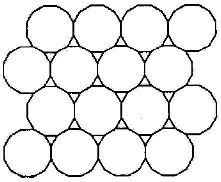
Regular tilings of the plane by *two or more* convex regular POLYGONS such that the same POLYGONS in the same order surround each VERTEX are called semiregular tilings. In the plane, there are eight such tessellations, illustrated below.

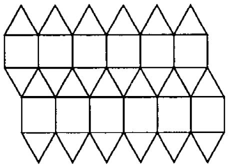


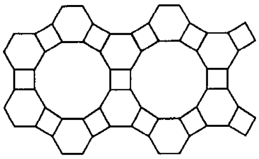


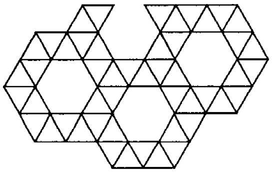












In 3-D, a POLYHEDRON which is capable of tessellating space is called a SPACE-FILLING POLYHEDRON. Examples include the CUBE, RHOMBIC DODECAHEDRON, and TRUNCATED OCTAHEDRON. There is also a 16-sided space-filler and a convex POLYHEDRON known as the SCHMITT-CONWAY BIPRISM which fills space only aperiodically.

A tessellation of n-D polytopes is called a HONEYCOMB.

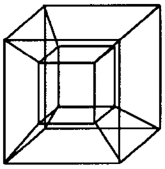
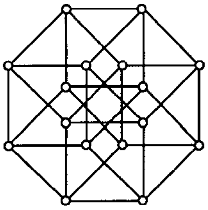
Tesseract





The HYPERCUBE in $\mathbb{R}^4$ is called a tesseract. It has the SCHLÄFLI SYMBOL $\{4,3,3\}$, and VERTICES $(\pm 1, \pm 1, \pm 1, \pm 1)$. The above figures show two visualizations of the TESSERACT. The figure on the left is a projection of the TESSERACT in 3-space (Gardner 1977), and the figure on the right is the GRAPH of the TESSERACT symmetrically projected into the PLANE (Coxeter 1973). A TESSERACT has 16 VERTICES, 32 EDGES, 4 SQUARES, and 8 CUBES.

Tetrahedral Number

A FIGURATE NUMBER Te_n of the form

$$Te_n = \sum_{i=1}^{n} T_n = \tfrac{1}{6}n(n+1)(n+2) = \binom{n+2}{3}, \qquad (1)$$

where T_n is the nth TRIANGULAR NUMBER and $\binom{n}{m}$ is a BINOMIAL COEFFICIENT. These numbers correspond to placing discrete points in the configuration of a TETRAHEDRON (triangular base pyramid). Tetrahedral numbers are PYRAMIDAL NUMBERS with $r = 3$, and are the sum of consecutive TRIANGULAR NUMBERS. The first few are 1, 4, 10, 20, 35, 56, 84, 120, ... (Sloane's A000292). The GENERATING FUNCTION of the tetrahedral numbers is

$$\frac{x}{(x-1)^4} = x + 4x^2 + 10x^3 + 20x^4 + \ldots. \qquad (2)$$

Tetrahedral numbers are EVEN, except for every fourth tetrahedral number, which is ODD (Conway and Guy 1996).

The only numbers which are simultaneously SQUARE and TETRAHEDRAL are $Te_1 = 1$, $Te_2 = 4$, and $Te_{48} = 19600$ (giving $S_1 = 1$, $S_2 = 4$, and $S_{140} = 19600$), as proved by Meyl (1878; cited in Dickson 1952, p. 25). Numbers which are simultaneously TRIANGULAR and tetrahedral satisfy the BINOMIAL COEFFICIENT equation

$$\binom{n}{2} = \binom{m}{3}, \qquad (3)$$

the only solutions of which are $(m, n) = (10, 16)$, (22, 56), and (36, 120) (Guy 1994, p. 147). Beukers (1988) has studied the problem of finding numbers which are simultaneously tetrahedral and PYRAMIDAL via INTEGER points on an ELLIPTIC CURVE, and finds that the only solution is the trivial $Te_1 = P_1 = 1$.

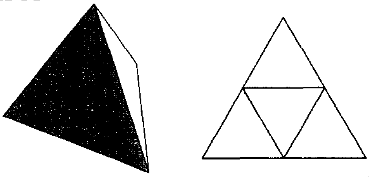
Tetrahedron



The regular tetrahedron, often simply called "the" tetrahedron, is the PLATONIC SOLID P_1 with four VERTICES, six EDGES, and four equivalent EQUILATERAL TRIANGULAR faces ($4\{3\}$). It is also UNIFORM POLYHEDRON U_1. It is described by the SCHLÄFLI SYMBOL $\{3,3\}$ and the WYTHOFF SYMBOL is $3\,|\,2\,3$. It is the prototype of the TETRAHEDRAL GROUP T_d,

The tetrahedron is its own DUAL POLYHEDRON. It is the only simple POLYHEDRON with no DIAGONALS, and cannot be STELLATED. The VERTICES of a tetrahedron are given by $(0,0,\sqrt{3})$, $(0,\frac{2}{3}\sqrt{6},-\frac{1}{3}\sqrt{3})$, $(-\sqrt{2},-\frac{1}{3}\sqrt{6},-\frac{1}{3}\sqrt{3})$, and $(\sqrt{2},-\frac{1}{3}\sqrt{6},-\frac{1}{3}\sqrt{3})$, or by (0, 0, 0), (0, 1, 1), (1, 0, 1), (1, 1, 0). In the latter case, the face planes are

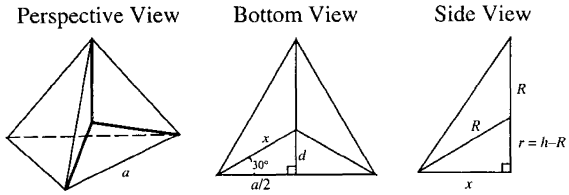
$$x+y+z=2 \tag{1}$$

$$x-y-z=0 \tag{2}$$

$$-x+y-z=0 \tag{3}$$

$$x+y-z=0. \tag{4}$$

Let a tetrahedron be length a on a side. The VERTICES are located at $(x, 0, 0)$, $(-d, \pm a/2, 0)$, and $(0, 0, h)$. From the figure,



$$x=\frac{\frac{a}{2}}{\cos(\frac{\pi}{6})}=\frac{1}{2}\frac{2}{\sqrt{3}}a=\tfrac{1}{3}\sqrt{3}\,a. \tag{5}$$

d is then

$$d=\sqrt{x^2-(\tfrac{1}{2}a)^2}=a\sqrt{\tfrac{1}{3}-\tfrac{1}{4}}=a\sqrt{\frac{4-3}{12}}=\frac{a}{\sqrt{12}}$$
$$=\tfrac{1}{6}\sqrt{3}\,a. \tag{6}$$

This gives the AREA of the base as

$$\begin{aligned}A&=\tfrac{1}{2}a(R+x)=\tfrac{1}{2}a\left(\frac{\sqrt{3}}{6}a+\frac{1}{\sqrt{3}}a\right)\\&=\tfrac{1}{2}a^2\left(\frac{\sqrt{3}}{6}+\frac{2\sqrt{3}}{6}\right)\\&=\tfrac{1}{2}a^2\frac{3\sqrt{3}}{6}=\tfrac{1}{4}\sqrt{3}\,a^2.\end{aligned} \tag{7}$$

The height is

$$h=\sqrt{a^2-x^2}=a\sqrt{1-\tfrac{1}{3}}=\tfrac{1}{3}\sqrt{6}\,a. \tag{8}$$

The CIRCUMRADIUS R is found from

$$x^2+(h-R)^2=R^2 \tag{9}$$

$$x^2+h^2-2hR+R^2=R^2. \tag{10}$$

Solving gives

$$R=\frac{x^2+h^2}{2h}=\frac{\frac{1}{3}+\frac{2}{3}}{2\sqrt{\frac{2}{3}}}=\frac{1}{2}\sqrt{\frac{3}{2}}=\tfrac{1}{4}\sqrt{6}\,a\approx 0.61237a. \tag{11}$$

The INRADIUS r is

$$r\equiv h-R=\sqrt{\frac{2}{3}}\,a-\frac{\sqrt{3}}{6}\,a=\tfrac{1}{12}\sqrt{6}\,a\approx 0.20412a, \tag{12}$$

which is also

$$r=\tfrac{1}{4}h=\tfrac{1}{3}R. \tag{13}$$

The MIDRADIUS is

$$\rho=\sqrt{r^2+d^2}=a\sqrt{\tfrac{6}{144}+\tfrac{3}{36}}=\sqrt{\tfrac{1}{8}}\,a=\tfrac{1}{4}\sqrt{2}\,a$$
$$\approx 0.35355a. \tag{14}$$

Plugging in for the VERTICES gives

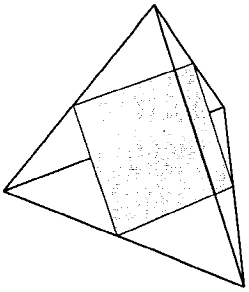
$$(a\sqrt{3},0,0),(-\tfrac{1}{6}\sqrt{3}\,a,\pm\tfrac{1}{2}a,0),\text{ and }(0,0,\tfrac{1}{3}\sqrt{6}\,a). \tag{15}$$

Since a tetrahedron is a PYRAMID with a triangular base, $V=\frac{1}{3}A_bh$, and

$$V=\tfrac{1}{3}\left(\tfrac{1}{4}\sqrt{3}\,a^2\right)\left(\sqrt{\frac{2}{3}}\,a\right)=\tfrac{1}{12}\sqrt{2}\,a^3. \tag{16}$$

The DIHEDRAL ANGLE is

$$\theta=\tan^{-1}(2\sqrt{2})=2\sin^{-1}(\tfrac{1}{3}\sqrt{6})=\cos^{-1}(\tfrac{1}{3}). \tag{17}$$



By slicing a tetrahedron as shown above, a SQUARE can be obtained. This cut divides the tetrahedron into two congruent solids rotated by 90°.

Now consider a general (not necessarily regular) tetrahedron, defined as a convex POLYHEDRON consisting of four (not necessarily identical) TRIANGULAR faces. Let the tetrahedron be specified by its VERTICES at (x_i, y_i) where $i = 1, \ldots, 4$. Then the VOLUME is given by

$$V = \frac{1}{3!}\begin{vmatrix} x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \\ x_4 & y_4 & z_4 & 1 \end{vmatrix}. \tag{18}$$

Specifying the tetrahedron by the three EDGE vectors **a**, **b**, and **c** from a given VERTEX, the VOLUME is

$$V = \tfrac{1}{3!}|\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})|. \tag{19}$$

If the faces are congruent and the sides have lengths a, b, and c, then

$$V = \sqrt{\frac{(a^2+b^2-c^2)(a^2+c^2-b^2)(b^2+c^2-a^2)}{72}} \tag{20}$$

(Klee and Wagon 1991, p. 205). Let a, b, c, and d be the areas of the four faces, and define

$$B \equiv \angle cd \tag{21}$$

$$C \equiv \angle bd \tag{22}$$

$$D \equiv \angle bc, \tag{23}$$

where $\angle jk$ means here the ANGLE between the PLANES formed by the FACES j and k, with VERTEX along their intersecting EDGE. Then

$$a^2 = b^2+c^2+d^2-2cd\cos B-2bd\cos C-2bc\cos D. \tag{24}$$

The analog of GAUSS'S CIRCLE PROBLEM can be asked for tetrahedra: how many LATTICE POINTS lie within a tetrahedron centered at the ORIGIN with a given INRADIUS (Lehmer 1940, Granville 1991, Xu and Yau 1992, Guy 1994).

Tetrahedron Inscribing

Pick four points at random on the surface of a unit SPHERE. Find the distribution of possible volumes of (nonregular) TETRAHEDRA. Without loss of generality, the first point can be chosen as (1, 0, 0). Designate the other points **a**, **b**, and **c**. Then the distances from the first VERTEX are

$$\mathbf{a} = \begin{bmatrix} \cos\theta_1 - 1 \\ \sin\theta_1 \\ 0 \end{bmatrix} \tag{1}$$

$$\mathbf{b} = \begin{bmatrix} \cos\theta_2 \sin\phi_2 - 1 \\ \sin\theta_2 \sin\phi_2 \\ \cos\phi_2 \end{bmatrix} \tag{2}$$

$$\mathbf{c} = \begin{bmatrix} \cos\theta_3 \sin\phi_3 - 1 \\ \sin\theta_3 \sin\phi_3 \\ \cos\phi_3 \end{bmatrix}. \tag{3}$$

The average volume is then

$$\bar{V} = \frac{1}{C}\int_0^{2\pi}\int_0^{2\pi}\int_0^{2\pi}\int_{-\pi/2}^{\pi/2}\int_{-\pi/2}^{\pi/2} \tfrac{1}{3!}|\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})| \, d\phi_3\, d\phi_2\, d\theta_3\, d\theta_2\, d\theta_1, \tag{4}$$

where

$$C = \int_0^{2\pi}\int_0^{2\pi}\int_0^{2\pi}\int_{-\pi/2}^{\pi/2} d\phi_3\, d\phi_2\, d\theta_3\, d\theta_2\, d\theta_1 = 8\pi^5 \tag{5}$$

and

$$\begin{aligned} \mathbf{a}\cdot(\mathbf{b}\times\mathbf{c}) = {} & -\cos\phi_2 \sin\theta_1 + \cos\phi_3 \sin\theta_1 \\ & -\cos\phi_3 \cos\theta_2 \sin\phi_2 \sin\theta_1 + \cos\phi_2 \cos\theta_3 \sin\phi_3 \sin\theta_1 \\ & -\cos\phi_3 \sin\phi_2 \sin\theta_2 + \cos\phi_3 \cos\theta_1 \sin\phi_2 \sin\theta_2 \\ & +\cos\phi_2 \sin\phi_3 \sin\theta_3 - \cos\phi_2 \cos\theta_1 \sin\phi_3 \sin\theta_3. \end{aligned} \tag{6}$$

The integrals are difficult to compute analytically, but 10^7 computer TRIALS give

$$\langle V\rangle \approx 0.1080 \tag{7}$$

$$\langle V^2\rangle \approx 0.02128 \tag{8}$$

$$\sigma_V{}^2 = \langle V^2\rangle - \langle V\rangle^2 \approx 0.009937. \tag{9}$$

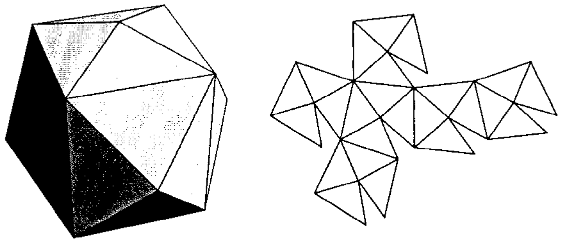
Tetrakis Hexahedron



The DUAL POLYHEDRON of the TRUNCATED OCTAHEDRON.

Tetranacci Number

The tetranacci numbers are a generalization of the FIBONACCI NUMBERS defined by $T_0 = 0$, $T_1 = 1$, $T_2 = 1$, $T_3 = 2$, and the RECURRENCE RELATION

$$T_n = T_{n-1} + T_{n-2} + T_{n-3} + T_{n-4}$$

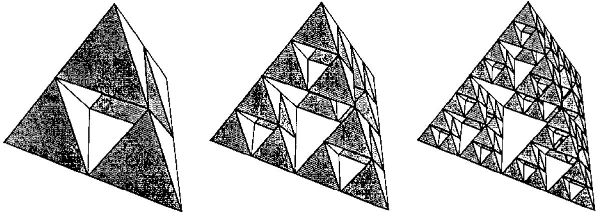
for $n \geq 4$. They represent the $n = 4$ case of the FIBONACCI n-STEP NUMBERS. The first few terms are 1, 1, 2, 4, 8, 15, 29, 56, 108, 208, ... (Sloane's A000078). The ratio of adjacent terms tends to 1.92756, which is the REAL ROOT of $x^5 - 2x^4 + 1 = 0$.

see also FIBONACCI n-STEP NUMBER, FIBONACCI NUMBER, TRIBONACCI NUMBER

References

Sloane, N. J. A. Sequence A000078/M1108 in "An On-Line Version of the Encyclopedia of Integer Sequences."

Tetrix



The 3-D analog of the SIERPIŃSKI SIEVE illustrated above, also called the SIERPIŃSKI SPONGE or SIERPIŃSKI TETRAHEDRON. Let N_n be the number of tetrahedra, L_n the length of a side, and A_n the fractional VOLUME of tetrahedra after the nth iteration. Then

$$N_n = 4^n \quad (1)$$

$$L_n = (\tfrac{1}{2})^n = 2^{-n} \quad (2)$$

$$A_n = {L_n}^3 N_n = (\tfrac{1}{2})^n. \quad (3)$$

The CAPACITY DIMENSION is therefore

$$\begin{aligned} d_{\text{cap}} &= -\lim_{n\to\infty} \frac{\ln N_n}{\ln L_n} = -\lim_{n\to\infty} \frac{\ln(4^n)}{\ln(2^{-n})} \\ &= \frac{\ln 4}{\ln 2} = \frac{2\ln 2}{\ln 2} = 2, \end{aligned} \quad (4)$$

so the tetrix has an INTEGRAL CAPACITY DIMENSION (albeit one less than the DIMENSION of the 3-D TETRAHEDRA from which it is built), despite the fact that it is a FRACTAL.

The following illustration demonstrates how this counterintuitive fact can be true by showing three stages of the rotation of a tetrix, viewed along one of its edges. In the last frame, the tetrix "looks" like the 2-D PLANE.

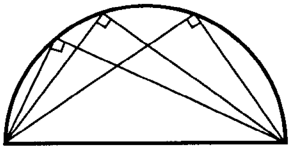
Thales' Theorem



An ANGLE inscribed in a SEMICIRCLE is a RIGHT ANGLE.

see also RIGHT ANGLE, SEMICIRCLE

Theorem

A statement which can be demonstrated to be true by accepted mathematical operations and arguments. In general, a theorem is an embodiment of some general principle that makes it part of a larger theory.

According to the Nobel Prize-winning physicist Richard Feynman (1985), any theorem, no matter how difficult to prove in the first place, is viewed as "TRIVIAL" by mathematicians once it has been proven. Therefore, there are exactly two types of mathematical objects: TRIVIAL ones, and those which have not yet been proven.

Theta Function

The theta functions are the elliptic analogs of the EXPONENTIAL FUNCTION, and may be used to express the JACOBI ELLIPTIC FUNCTIONS. Let t be a constant COMPLEX NUMBER with $\Im[t] > 0$. Define the NOME

$$q \equiv e^{i\pi t} = e^{\pi K'(k)/K(k)}, \tag{1}$$

where

$$t \equiv -i\frac{K'(k)}{K(k)}, \tag{2}$$

and $K(k)$ is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND, k is the MODULUS, and k' is the complementary MODULUS. Then the theta functions are, in the NOTATION of Whittaker and Watson,

$$\begin{aligned}\vartheta_1(z,q) &\equiv 2\sum_{n=0}^{\infty}(-1)^n q^{(n+1/2)^2}\sin[(2n+1)z]\\ &= zq^{1/4}\sum_{n=0}^{\infty}(-1)^n q^{n(n+1)}\sin[(2n+1)z] \qquad (3)\end{aligned}$$

$$\begin{aligned}\vartheta_2(z,q) &\equiv 2\sum_{n=0}^{\infty} q^{(n+1/2)^2}\cos[(2n+1)z]\\ &= 2q^{1/4}\sum_{n=0}^{\infty} q^{n(n+1)}\cos[(2n+1)z] \qquad (4)\end{aligned}$$

$$\vartheta_3(z,q) \equiv 1+2\sum_{n=1}^{\infty} q^{n^2}\cos(2nz) \tag{5}$$

$$\begin{aligned}\vartheta_4(z,q) &\equiv \sum_{n=-\infty}^{\infty}(-1)^n q^{n^2} e^{2niz}\\ &= 1+2\sum_{n=1}^{\infty}(-1)^n q^{n^2}\cos(2nz). \qquad (6)\end{aligned}$$

Written in terms of t,

$$\vartheta_2(t,q) = \sum_{n=-\infty}^{\infty} q^{(n+1/2)^2} e^{\Im[t]} \tag{7}$$

$$\vartheta_3(t,q) = \sum_{n=-\infty}^{\infty} q^{n^2} e^{\Im[t]}. \tag{8}$$

These functions are sometimes denoted Θ_i or θ_i, and a number of indexing conventions have been used. For a summary of these notations, see Whittaker and Watson (1990). The theta functions are quasidoubly periodic, as illustrated in the following table.

ϑ_i	$\vartheta_i(z+\pi)/\vartheta_i(z)$	$\vartheta_i(z+t\pi)/\vartheta_i(z)$
ϑ_1	-1	$-N$
ϑ_2	-1	N
ϑ_3	1	N
ϑ_4	1	$-N$

Here,

$$N \equiv q^{-1}e^{-2iz}. \tag{9}$$

The quasiperiodicity can be established as follows for the specific case of ϑ_4,

$$\begin{aligned}\vartheta_4(z+\pi,q) &= \sum_{n=-\infty}^{\infty}(-1)^n q^{n^2} e^{2niz} e^{2ni\pi}\\ &= \sum_{n=-\infty}^{\infty}(-1)^n q^{n^2} e^{2niz} = \vartheta_4(z,q) \qquad (10)\end{aligned}$$

$$\begin{aligned}\vartheta_4(z+\pi t,q) &= \sum_{n=-\infty}^{\infty}(-1)^n q^{n^2} e^{2ni\pi t} e^{2niz}\\ &= \sum_{n=-\infty}^{\infty}(-1)^n q^{n^2} q^{2n} e^{2niz}\\ &= -q^{-1}e^{-2iz}\sum_{n=-\infty}^{\infty}(-1)^{n+1} q^{(n+1)^2} q^{2(n+1)iz}\\ &= -q^{-1}e^{-2iz}\sum_{n=-\infty}^{\infty}(-1)^n q^{n^2} q^{2niz}\\ &= -q^{-1}e^{-2iz}\vartheta_4(z,q). \qquad (11)\end{aligned}$$

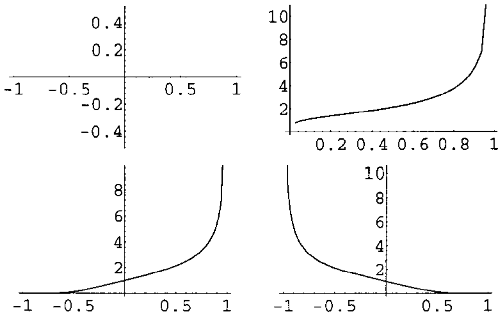
The theta functions can be written in terms of each other:

$$\vartheta_1(z,q) = -ie^{iz+\pi it/4}\vartheta_4(z+\tfrac{1}{4}\pi t,q) \tag{12}$$

$$\vartheta_2(z,q) = \vartheta_1(z+\tfrac{1}{2}\pi,q) \tag{13}$$

$$\vartheta_3(z,q) = \vartheta_4(z+\tfrac{1}{2}\pi,q). \tag{14}$$

Any theta function of given arguments can be expressed in terms of any other two theta functions with the same arguments.



Define

$$\vartheta_i \equiv \vartheta_i(z=0), \tag{15}$$

which are plotted above. Then we have the identities

$$\vartheta_1{}^2(z)\vartheta_4{}^2 = \vartheta_3{}^2(z)\vartheta_2{}^2 - \vartheta_2{}^2(z)\vartheta_3{}^2 \tag{16}$$

$$\vartheta_2{}^2(z)\vartheta_4{}^2 = \vartheta_4{}^2(z)\vartheta_2{}^2 - \vartheta_1{}^2(z)\vartheta_3{}^2 \tag{17}$$

$$\vartheta_3{}^2(z)\vartheta_4{}^2 = \vartheta_4{}^2(z)\vartheta_3{}^2 - \vartheta_1{}^2(z)\vartheta_2{}^2 \tag{18}$$

$$\vartheta_4{}^2(z)\vartheta_4{}^2 = \vartheta_3{}^2(z)\vartheta_3{}^2 - \vartheta_2{}^2(z)\vartheta_2{}^2. \tag{19}$$

Taking $z = 0$ in the last gives the special case

$$\vartheta_4{}^4 = \vartheta_3{}^4 - \vartheta_2{}^4. \tag{20}$$

In addition,

$$\vartheta_3(x) = \sum_{n=-\infty}^{\infty} x^{n^2} = 1 + 2x + 2x^4 + 2x^9 + \ldots \tag{21}$$

$$\vartheta_3{}^2(x) = 1 + 4\left(\frac{x}{1-x} - \frac{x^3}{1-x^3} + \frac{x^5}{1-x^5} - \frac{x^7}{1-x^7} + \ldots\right) \tag{22}$$

$$\vartheta_3{}^4(x) = 1 + 8\left(\frac{x}{1-x} + \frac{2x^2}{1+x^2} + \frac{3x^3}{1-x^3} + \frac{4x^4}{1+x^4} + \ldots\right). \tag{23}$$

The theta functions obey addition rules such as

$$\vartheta_3(z+y)\vartheta_3(z-y)\vartheta_3{}^2 = \vartheta_3{}^2(y)\vartheta_3{}^2(z) + \vartheta_1{}^2(y)\vartheta_1{}^2(z). \tag{24}$$

Letting $y = z$ gives a duplication FORMULA

$$\vartheta_3(2z)\vartheta_3{}^3 = \vartheta_3{}^4(z) + \vartheta_1{}^4(z). \tag{25}$$

For more addition FORMULAS, see Whittaker and Watson (1990, pp. 487–488). Ratios of theta function derivatives to the functions themselves have the simple forms

$$\frac{\vartheta_1'(z)}{\vartheta_1(z)} = \cot z + 4\sum_{n=1}^{\infty} \frac{q^{2n}}{1-q^{2n}} \sin(2nz) \tag{26}$$

$$\frac{\vartheta_2'(z)}{\vartheta_2(z)} = -\tan z + 4\sum_{n=1}^{\infty} (-1)^n \frac{q^{2n}}{1-q^{2n}} \sin(2nz) \tag{27}$$

$$\frac{\vartheta_3'(z)}{\vartheta_3(z)} = 4\sum_{n=1}^{\infty} (-1)^n \frac{q^n}{1-q^{2n}} \sin(2nz) \tag{28}$$

$$\begin{aligned}\frac{\vartheta_4'(z)}{\vartheta_4(z)} &= \sum_{n=1}^{\infty} \frac{q^{2n-1}\sin(2z)}{1-2q^{2n-1}\cos(2z)+q^{4n-2}} \\ &= \sum_{n=1}^{\infty} \frac{4q^n \sin(2nz)}{1-q^{2n}}.\end{aligned} \tag{29}$$

The theta functions can be expressed as products instead of sums by

$$\vartheta_1(z) = 2Gq^{1/4}\sin z \prod_{n=1}^{\infty}[1 - 2q^{2n}\cos(2z) + q^{4n}] \tag{30}$$

$$\vartheta_2(z) = 2Gq^{1/4}\cos z \prod_{n=1}^{\infty}[1 + 2q^{2n}\cos(2z) + q^{4n}] \tag{31}$$

$$\vartheta_3(z) = G\prod_{n=1}^{\infty}[1 + 2q^{2n-1}\cos(2z) + q^{4n-2}] \tag{32}$$

$$\vartheta_4(z) = G\prod_{n=1}^{\infty}[1 - 2q^{2n-1}\cos(2z) + q^{4n-2}], \tag{33}$$

where

$$G \equiv \prod_{n=1}^{\infty}(1 - q^{2n}) \tag{34}$$

(Whittaker and Watson 1990, pp. 469–470).

The theta functions satisfy the PARTIAL DIFFERENTIAL EQUATION

$$\tfrac{1}{4}\pi i\frac{\partial^2 y}{\partial z^2} + \frac{\partial y}{\partial t} = 0, \tag{35}$$

where $y \equiv \vartheta_j(z|t)$. Ratios of the theta functions with ϑ_4 in the DENOMINATOR also satisfy differential equations

$$\frac{d}{dz}\left[\frac{\vartheta_1(z)}{\vartheta_4(z)}\right] = \vartheta_4{}^2\frac{\vartheta_2(z)\vartheta_3(z)}{\vartheta_4{}^2(z)} \tag{36}$$

$$\frac{d}{dz}\left[\frac{\vartheta_2(z)}{\vartheta_4(z)}\right] = -\vartheta_3{}^2\frac{\vartheta_1(z)\vartheta_3(z)}{\vartheta_4{}^2(z)} \tag{37}$$

$$\frac{d}{dz}\left[\frac{\vartheta_3(z)}{\vartheta_4(z)}\right] = -\vartheta_2{}^2\frac{\vartheta_1(z)\vartheta_2(z)}{\vartheta_4{}^2(z)}. \tag{38}$$

Some additional remarkable identities are

$$\vartheta_1' = \vartheta_2\vartheta_3\vartheta_4 \tag{39}$$

$$\vartheta_3(z,t) = -(it)^{1/2}e^{z^2/\pi it}\vartheta_3\left(\frac{2}{t}, -\frac{1}{t}\right), \tag{40}$$

which were discovered by Poisson in 1827 and are equivalent to

$$\sum_{n=-\infty}^{\infty} e^{-t(x+n)^2} = \sqrt{\frac{\pi}{t}}\sum_{k=-\infty}^{\infty} 2^{2\pi ikx-(\pi^2k^2/t)}. \tag{41}$$

Another amazing identity is

$$\begin{aligned}&2\vartheta_1[\tfrac{1}{2}(-b+c+d+e)]\vartheta_2[\tfrac{1}{2}(b-c+d+e)]\vartheta_3[\tfrac{1}{2}(b+c-d+e)] \\ &\quad\times\vartheta_4[\tfrac{1}{2}(b+c+d-e)] = \vartheta_3(b)\vartheta_4(c)\vartheta_1(d)\vartheta_2(e) \\ &\quad+\vartheta_2(b)\vartheta_1(c)\vartheta_4(d)\vartheta_3(e) - \vartheta_1(b)\vartheta_2(c)\vartheta_3(d)\vartheta_4(e) \\ &\quad+\vartheta_4(b)\vartheta_3(c)\vartheta_2(d)\vartheta_1(e)\end{aligned} \tag{42}$$

(Whittaker and Watson 1990, p. 469).

The complete ELLIPTIC INTEGRALS OF THE FIRST and SECOND KINDS can be expressed using theta functions. Let

$$\xi \equiv \frac{\vartheta_1(z)}{\vartheta_4(z)}, \tag{43}$$

and plug into (36)

$$\left(\frac{d\xi}{dz}\right)^2 = ({\vartheta_2}^2 - \xi^2{\vartheta_3}^2)({\vartheta_3}^2 - \xi^2{\vartheta_2}^2). \tag{44}$$

Now write

$$\xi\frac{\vartheta_3}{\vartheta_2} \equiv y \tag{45}$$

and

$$z{\vartheta_3}^2 \equiv u. \tag{46}$$

Then

$$\left(\frac{dy}{du}\right)^2 = (1-y^2)(1-k^2y^2), \tag{47}$$

where the MODULUS is defined by

$$k = k(q) = \frac{{\vartheta_2}^2(q)}{{\vartheta_3}^2(q)}. \tag{48}$$

Define also the complementary MODULUS

$$k' = k'(q) = \frac{{\vartheta_4}^2(-q)}{{\vartheta_3}^2(q)}. \tag{49}$$

Now, since

$${\vartheta_2}^4 + {\vartheta_4}^4 = {\vartheta_3}^4, \tag{50}$$

we have shown

$$k^2 + k'^2 = 1. \tag{51}$$

The solution to the equation is

$$y = \frac{\vartheta_3}{\vartheta_2}\frac{\vartheta_1(u{\vartheta_3}^{-2}|t)}{\vartheta_4(u{\vartheta_3}^{-2}|t)} \equiv \mathrm{sn}(u,k), \tag{52}$$

which is a JACOBI ELLIPTIC FUNCTION with periods

$$4K(k) = 2\pi{\vartheta_3}^2(q) \tag{53}$$

and

$$2iK'(k) = \pi t{\vartheta_3}^2(q). \tag{54}$$

Here, K is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND,

$$K(k) = \tfrac{1}{2}\pi{\vartheta_3}^2(q). \tag{55}$$

Thomson Lamp Paradox

A lamp is turned on for 1/2 minute, off for 1/4 minute, on for 1/8 minute, etc. At the end of one minute, the lamp switch will have been moved $\aleph_0$ times, where $\aleph_0$ is ALEPH-0. Will the lamp be on or off? This PARADOX is actually nonsensical, since it is equivalent to asking if the "last" INTEGER is EVEN or ODD.

Thomson Problem

Determine the stable equilibrium positions of N classical electrons constrained to move on the surface of a SPHERE and repelling each other by an inverse square law. Exact solutions for $N = 2$ to 8 are known, but $N = 9$ and 11 are still unknown.

In reality, Earnshaw's theorem guarantees that no system of discrete electric charges can be held in stable equilibrium under the influence of their electrical interaction alone (Aspden 1987).

Thue Constant

The base-2 TRANSCENDENTAL NUMBER

$$0.11011011111011011111\ldots_2,$$

where the nth bit is 1 if n is not divisible by 3 and is the complement of the $(n/3)$th bit if n is divisible by 3. It is also given by the SUBSTITUTION MAP

$$\begin{aligned} 0 &\to 111 \\ 1 &\to 110. \end{aligned}$$

In decimal, the Thue constant equals 0.8590997969....

see also RABBIT CONSTANT, THUE-MORSE CONSTANT

References

Thue-Morse Constant

The constant also called the PARITY CONSTANT and defined by

$$P \equiv \tfrac{1}{2}\sum_{n=0}^{\infty} P(n)2^{-n} = 0.4124540336401075977\ldots \quad (1)$$

(Sloane's A014571), where $P(n)$ is the PARITY of n. Dekking (1977) proved that the Thue-Morse constant is TRANSCENDENTAL, and Allouche and Shallit give a complete proof correcting a minor error of Dekking.

The Thue-Morse constant can be written in base 2 by stages by taking the previous iteration a_n, taking the complement $\overline{a_n}$, and appending, producing

$$\begin{aligned} a_0 &= 0.0_2 \\ a_1 &= 0.01_2 \\ a_2 &= 0.0110_2 \\ a_3 &= 0.01101001_2 \\ a_4 &= 0.0110100110010110_2. \end{aligned} \quad (2)$$

This can be written symbolically as

$$a_{n+1} = a_n + \overline{a_n} \cdot 2^{-2^n} \quad (3)$$

with $a_0 = 0$. Here, the complement is the number $\overline{a_n}$ such that $a_n + \overline{a_n} = 0.11\ldots_2$, which can be found from

$$a_n + \overline{a_n} = \sum_{k=1}^{2^n} (\tfrac{1}{2})^k = \frac{1 - (\frac{1}{2})^{2^n}}{1 - \frac{1}{2}} - 1 = 1 - 2^{-2^n}. \quad (4)$$

Therefore,

$$\overline{a_n} = 1 - a_n - 2^{-2^n}, \tag{5}$$

and

$$a_{n+1} = a_n + (1 - 2^{-2^n} - a_n)2^{-2^n}. \tag{6}$$

The regular CONTINUED FRACTION for the Thue-Morse constant is [0 2 2 2 1 4 3 5 2 1 4 2 1 5 44 1 4 1 2 4 1 1 1 5 14 1 50 15 5 1 1 1 4 2 1 4 1 43 1 4 1 2 1 3 16 1 2 1 2 1 50 1 2 424 1 2 5 2 1 1 1 5 5 2 22 5 1 1 1 1274 3 5 2 1 1 1 4 1 1 15 154 7 2 1 2 2 1 2 1 1 50 1 4 1 2 867374 1 1 1 5 5 1 1 6 1 2 7 2 1650 23 3 1 1 1 2 5 3 84 1 1 1 1284 ...] (Sloane's A014572), and seems to continue with sporadic large terms in suspicious-looking patterns. A nonregular CONTINUED FRACTION is

$$P = \cfrac{1}{3 - \cfrac{1}{2 - \cfrac{1}{4 - \cfrac{3}{16 - \cfrac{15}{256 - \cfrac{255}{65536 - \ldots}}}}}}. \tag{7}$$

A related infinite product is

$$4P = 2 - \frac{1 \cdot 3 \cdot 15 \cdot 255 \cdot 65535 \cdots}{2 \cdot 4 \cdot 16 \cdot 256 \cdot 65536 \cdots}. \tag{8}$$

The SEQUENCE $a_\infty = 0110100110010110100101100\ldots$ (Sloane's A010060) is known as the THUE-MORSE SEQUENCE.

Thue-Morse Sequence

The INTEGER SEQUENCE (also called the MORSE-THUE SEQUENCE)

$$0110100110010110100101100110 1001\ldots \tag{1}$$

(Sloane's A010060) which arises in the THUE-MORSE CONSTANT. It can be generated from the SUBSTITUTION MAP

$$0 \to 01 \tag{2}$$

$$1 \to 10 \tag{3}$$

starting with 0 as follows:

$$0 \to 01 \to 0110 \to 01101001 \to \ldots. \tag{4}$$

Writing the sequence as a POWER SERIES over the GALOIS FIELD GF(2),

$$F(x) = 0 + 1x + 1x^2 + 0x^3 + 1x^4 + \ldots, \tag{5}$$

then F satisfies the quadratic equation

$$(1+x)F^2 + F = \frac{x}{1+x^2} \pmod{2}. \tag{6}$$

This equation has two solutions, F and F', where F' is the complement of F, i.e.,

$$F + F' = 1 + x + x^2 + x^3 + \ldots = \frac{1}{1+x}, \tag{7}$$

which is consistent with the formula for the sum of the roots of a quadratic. The equality (6) can be demonstrated as follows. Let $(abcdef\ldots)$ be a shorthand for the POWER series

$$a + bx + cx^2 + dx^3 + \ldots, \tag{8}$$

so $F(x)$ is $(0110100110010110\ldots)$. To get F^2, simply use the rule for squaring POWER SERIES over GF(2)

$$(A+B)^2 = A^2 + B^2 \pmod{2}, \tag{9}$$

which extends to the simple rule for squaring a POWER SERIES

$$(a_0 + a_1x + a_2x^2 + \ldots)^2 = a_0 + a_1x^2 + a_2x^4 + \ldots \pmod{2}, \tag{10}$$

i.e., space the series out by a factor of 2, (0 1 1 0 1 0 0 1 ...), and insert zeros in the ODD places to get

$$F^2 = (0010100010000010\ldots). \tag{11}$$

Then multiply by x (which just adds a zero at the front) to get

$$xF^2 = (00010100010000010\ldots). \tag{12}$$

Adding to F^2 gives

$$(1+x)F^2 = (0011110011000011\ldots). \tag{13}$$

This is the first term of the quadratic equation, which is the Thue-Morse sequence with each term doubled up. The next term is F, so we have

$$(1+x)F^2 = (0011110011000011\ldots) \tag{14}$$

$$F = (0110100110010110\ldots). \tag{15}$$

The sum is the above two sequences XORed together (there are no CARRIES because we're working over GF(2)), giving

$$(1+x)F^2+F=(0101010101010101\ldots). \tag{16}$$

We therefore have

$$\begin{aligned}(1+x)F^2+F&=\frac{x}{1+x^2}\\&=x+x^3+x^5+x^7+x^9+x^{11}+\ldots\pmod 2.\end{aligned} \tag{17}$$

The Thue-Morse sequence is an example of a cube-free sequence on two symbols (Morse and Hedlund 1944), i.e., it contains no substrings of the form WWW, where W is any WORD. For example, it does not contain the WORDS 000, 010101 or 010010010. In fact, the following stronger statement is true: the Thue-Morse sequence does not contain any substrings of the form WWa, where a is the first symbol of W. We can obtain a SQUAREFREE sequence on three symbols by doing the following: take the Thue-Morse sequence 0110100110010110... and look at the sequence of WORDS of length 2 that appear: 01 11 10 01 10 00 01 11 10 .... Replace 01 by 0, 10 by 1, 00 by 2 and 11 by 2 to get the following: 021012021.... Then this SEQUENCE is SQUAREFREE (Morse and Hedlund 1944).

The Thue-Morse sequence has important connections with the GRAY CODE. Kindermann generates fractal music using the SELF-SIMILARITY of the Thue-Morse sequence.

Thurston's Geometrization Conjecture

Thurston's conjecture has to do with geometric structures on 3-D MANIFOLDS. Before stating Thurston's conjecture, some background information is useful. 3-dimensional MANIFOLDS possess what is known as a standard 2-level DECOMPOSITION. First, there is the CONNECTED SUM DECOMPOSITION, which says that every COMPACT 3-MANIFOLD is the CONNECTED SUM of a unique collection of PRIME 3-MANIFOLDS.

The second DECOMPOSITION is the JACO-SHALEN-JOHANNSON TORUS DECOMPOSITION, which states that irreducible orientable COMPACT 3-MANIFOLDS have a canonical (up to ISOTOPY) minimal collection of disjointly EMBEDDED incompressible TORI such that each component of the 3-MANIFOLD removed by the TORI is either "atoroidal" or "Seifert-fibered."

Thurston's conjecture is that, after you split a 3-MANIFOLD into its CONNECTED SUM and then JACO-SHALEN-JOHANNSON TORUS DECOMPOSITION, the remaining components each admit exactly one of the following geometries:

1. EUCLIDEAN GEOMETRY,
2. HYPERBOLIC GEOMETRY,
3. SPHERICAL GEOMETRY,
4. the GEOMETRY of $\mathbb{S}^2\times\mathbb{R}$,
5. the GEOMETRY of $\mathbb{H}^2\times\mathbb{R}$,
6. the GEOMETRY of SL_2R,
7. NIL GEOMETRY, or
8. SOL GEOMETRY.

Here, $\mathbb{S}^2$ is the 2-Sphere and $\mathbb{H}^2$ is the Hyperbolic Plane. If Thurston's conjecture is true, the truth of the Poincaré Conjecture immediately follows.

Thwaites Conjecture

see Collatz Problem

Tic-Tac-Toe

The usual game of tic-tac-toe (also called Ticktacktoe) is 3-in-a-row on a 3 × 3 board. However, a generalized n-in-a-Row on an $n \times m$ board can also be considered. For $n = 1$ and 2 the first player can always win. If the board is at least 3 × 4, the first player can win for $n = 3$.

However, for Tic-Tac-Toe which uses a 3 × 3 board, a draw can always be obtained. If the board is at least 4 × 30, the first player can win for $n = 4$. For $n = 5$, a draw can always be obtained on a 5 × 5 board, but the first player can win if the board is at least 15 × 15. The cases $n = 6$ and 7 have not yet been fully analyzed for an $n \times n$ board, although draws can always be forced for $n = 8$ and 9. On an $\infty \times \infty$ board, the first player can win for $n = 1$, 2, 3, and 4, but a tie can always be forced for $n \geq 8$. For $3 \times 3 \times 3$ and $4 \times 4 \times 4$, the first player can always win (Gardner 1979).

Tightly Embedded

Q is said to be tightly embedded if $|Q \cap Q^g|$ is Odd for all $g \in G - N_G(Q)$, where $N_G(Q)$ is the Normalizer of Q in G.

Tiling

A plane-filling arrangement of plane figures or its generalization to higher dimensions. Formally, a tiling is a collection of disjoint open sets, the closures of which cover the plane. Given a single tile, the so-called first Corona is the set of all tiles that have a common boundary point with the tile (including the original tile itself).

Wang's Conjecture (1961) stated that if a set of tiles tiled the plane, then they could always be arranged to do so periodically. A periodic tiling of the Plane by Polygons or Space by Polyhedra is called a Tessellation. The conjecture was refuted in 1966 when R. Berger showed that an aperiodic set of 20,426 tiles exists. By 1971, R. Robinson had reduced the number to six and, in 1974, R. Penrose discovered an aperiodic set (when color-matching rules are included) of two tiles: the so-called Penrose Tiles. (Penrose also sued the Kimberly Clark Corporation over their quilted toilet paper, which allegedly resembles a Penrose aperiodic tiling; Mirsky 1997.)

It is not known if there is a single aperiodic tile.

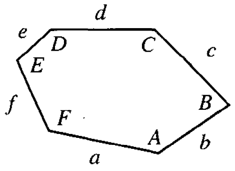
n-gon	tilings
3	any
4	any
5	14
6	3

The number of tilings possible for convex irregular Polygons are given in the above table. Any Triangle or convex Quadrilateral tiles the plane. There are at least 14 classes of convex Pentagonal tilings. There are at least three aperiodic tilings of Hexagons, given by the following types:

$$\begin{array}{cc} A+B+C=360^\circ & a=d \\ A+B+D=360^\circ & a=d, c=e \\ A=C=E & a=b, c=d, e=f \end{array} \tag{1}$$

(Gardner 1988). Note that the periodic hexagonal Tessellation is a degenerate case of all three tilings with

$$A=B=C=D=E=F \qquad a=b=c=d=e=f. \tag{2}$$



There are no tilings for convex n-gons for $n \geq 7$.

Tiling Theorem

Due to Lebesgue and Brouwer. If an n-D figure is covered in any way by sufficiently small subregions, then there will exist points which belong to at least $n+1$ of these subareas. Moreover, it is always possible to find a covering by arbitrarily small regions for which no point will belong to more than $n+1$ regions.

Titchmarsh Theorem

If $f(\omega)$ is SQUARE INTEGRABLE over the REAL ω axis, then any one of the following implies the other two:

1. The FOURIER TRANSFORM of $f(\omega)$ is 0 for $t < 0$.
2. Replacing ω by z, the function $f(z)$ is analytic in the COMPLEX PLANE z for $y > 0$ and approaches $f(x)$ almost everywhere as $y \to 0$. Furthermore, $\int_{-\infty}^{\infty} |f(x+iy)|^2\,dx < k$ for some number k and $y > 0$ (i.e., the integral is bounded).
3. The REAL and IMAGINARY PARTS of $f(z)$ are HILBERT TRANSFORMS of each other.

Tits Group

A finite SIMPLE GROUP which is a SUBGROUP of the TWISTED CHEVALLEY GROUP $^2F_4(2)$.

Toeplitz Matrix

Given $2N-1$ numbers r_k where $k = -N+1, \ldots, -1, 0, 1, \ldots, N-1$, a MATRIX of the form

$$\begin{bmatrix} r_0 & r_{-1} & r_{-2} & \cdots & r_{-n+1} \\ r_1 & r_0 & r_{-1} & \cdots & r_{-n+2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ r_{n-1} & r_{n-2} & r_{n-3} & \cdots & r_0 \end{bmatrix}$$

is called a Toeplitz matrix. MATRIX equations of the form

$$\sum_{j=1}^{N} r_{i-j}x_j = y_i$$

can be solved with $\mathcal{O}(N^2)$ operations.

Togliatti Surface

Togliatti (1940, 1949) showed that QUINTIC SURFACES having 31 ORDINARY DOUBLE POINTS exist, although he did not explicitly derive equations for such surfaces. Beauville (1978) subsequently proved that 31 double points are the maximum possible, and quintic surfaces having 31 ORDINARY DOUBLE POINTS are therefore sometimes called Togliatti surfaces. van Straten (1993) subsequently constructed a 3-D family of solutions and in 1994, Barth derived the example known as the DERVISH.

Tomography

Tomography is the study of the reconstruction of 2- and 3-dimensional objects from 1-dimensional slices. The RADON TRANSFORM is an important tool in tomography.

Rather surprisingly, there exist certain sets of four directions in Euclidean n-space such that X-rays of a convex body in these directions distinguish it from all other convex bodies.

Topological Basis

A topological basis is a SUBSET B of a SET T in which all other OPEN SETS can be written as UNIONS or finite INTERSECTIONS of B. For the REAL NUMBERS, the SET of all OPEN INTERVALS is a basis.

Topological Completion

The topological completion C of a FIELD F with respect to the ABSOLUTE VALUE $|\cdot|$ is the smallest FIELD containing F for which all CAUCHY SEQUENCES or rationals converge.

Topologically Conjugate

Two MAPS $\phi, \psi : M \to M$ are said to be topologically conjugate if there EXISTS a HOMEOMORPHISM $h : M \to M$ such that $\phi \circ h = h \circ \psi$, i.e., h maps ψ-orbits onto ϕ-orbits. Two maps which are topologically conjugate cannot be distinguished topologically.

see also ANOSOV DIFFEOMORPHISM, STRUCTURALLY STABLE

Topological Dimension

see LEBESGUE COVERING DIMENSION

Topological Entropy

The topological entropy of a MAP M is defined as

$$h_T(M) = \sup_{\{W_i\}} h(M, \{W_i\}),$$

where $\{W_i\}$ is a partition of a bounded region W containing a probability measure which is invariant under M, and sup is the SUPREMUM.

References

Ott, E. *Chaos in Dynamical Systems.* New York: Cambridge University Press, pp. 143–144, 1993.

Topological Groupoid

A topological groupoid over B is a GROUPOID G such that B and G are TOPOLOGICAL SPACES and α, β, and multiplication are continuous maps. Here, α and β are maps from G onto $\mathbb{R}^2$ with $\alpha : (x, \gamma, y) \mapsto x$ and $\beta : (x, \gamma, y) \mapsto y$.

References
Weinstein, A. "Groupoids: Unifying Internal and External Symmetry." *Not. Amer. Math. Soc.* **43**, 744–752, 1996.

Topological Manifold

A TOPOLOGICAL SPACE M satisfying some separability (i.e., it is a HAUSDORFF SPACE) and countability (i.e., it is a PARACOMPACT SPACE) conditions such that every point $p \in M$ has a NEIGHBORHOOD homeomorphic to an OPEN SET in $\mathbb{R}^n$ for some $n \geq 0$. Every SMOOTH MANIFOLD is a topological manifold, but not necessarily vice versa. The first nonsmooth topological manifold occurs in 4-D.

Nonparacompact manifolds are of little use in mathematics, but non-Hausdorff manifolds do occasionally arise in research (Hawking and Ellis 1975). For manifolds, Hausdorff and second countable are equivalent to Hausdorff and paracompact, and both are equivalent to the manifold being embeddable in some large-dimensional Euclidean space.

Topological Vector Space

A TOPOLOGICAL SPACE such that the two algebraic operations of VECTOR SPACE are continuous in the topology.

References
Köthe, G. *Topological Vector Spaces.* New York: Springer-Verlag, 1979.

Topologically Transitive

A FUNCTION f is topologically transitive if, given any two intervals U and V, there is some POSITIVE INTEGER k such that $f^k(U) \cap V = \varnothing$. Vaguely, this means that neighborhoods of points eventually get flung out to "big" sets so that they don't necessarily stick together in one localized clump.

see also CHAOS

Topology

Topology is the mathematical study of properties of objects which are preserved through deformations, twistings, and stretchings. (Tearing, however, is not allowed.) A CIRCLE is topologically equivalent to an ELLIPSE (into which it can be deformed by stretching) and a SPHERE is equivalent to an ELLIPSOID. Continuing along these lines, the SPACE of all positions of the minute hand on a clock is topologically equivalent to a CIRCLE (where SPACE of all positions means "the collection of all positions"). Similarly, the SPACE of all positions of the minute and hour hands is equivalent to a TORUS. The SPACE of all positions of the hour, minute and second hands form a 4-D object that cannot be visualized quite as simply as the former objects since it cannot be placed in our 3-D world, although it can be visualized by other means.

There is more to topology, though. Topology began with the study of curves, surfaces, and other objects in the plane and 3-space. One of the central ideas in topology is that spatial objects like CIRCLES and SPHERES can be treated as objects in their own right, and knowledge of objects is independent of how they are "represented" or "embedded" in space. For example, the statement "if you remove a point from a CIRCLE, you get a line segment" applies just as well to the CIRCLE as to an ELLIPSE, and even to tangled or knotted CIRCLES, since the statement involves only topological properties.

Topology has to do with the study of spatial objects such as curves, surfaces, the space we call our universe, the space-time of general relativity, fractals, knots, manifolds (objects with some of the same basic spatial properties as our universe), phase spaces that are encountered in physics (such as the space of hand-positions of a clock), symmetry groups like the collection of ways of rotating a top, etc.

The "objects" of topology are often formally defined as TOPOLOGICAL SPACES. If two objects have the same topological properties, they are said to be HOMEOMORPHIC (although, strictly speaking, properties that are not destroyed by stretching and distorting an object are really properties preserved by ISOTOPY, not HOMEOMORPHISM; ISOTOPY has to do with distorting embedded objects, while HOMEOMORPHISM is intrinsic).

Topology is divided into ALGEBRAIC TOPOLOGY (also called COMBINATORIAL TOPOLOGY), DIFFERENTIAL TOPOLOGY, and LOW-DIMENSIONAL TOPOLOGY.

There is also a formal definition for a topology defined in terms of set operations. A SET X along with a collection T of SUBSETS of it is said to be a topology if the SUBSETS in T obey the following properties:

1. The (trivial) subsets X and the EMPTY SET $\varnothing$ are in T.
2. Whenever sets A and B are in T, then so is $A \cap B$.
3. Whenever two or more sets are in T, then so is their UNION

(Bishop and Goldberg 1980).

A SET X for which a topology T has been specified is called a TOPOLOGICAL SPACE (Munkres 1975, p. 76). For example, the SET $X = \{0, 1, 2, 3\}$ together with the SUBSETS $T = \{0\}, \{1, 2, 3\}, \varnothing, \{0, 1, 2, 3\}\}$ comprises a topology, and X is a TOPOLOGICAL SPACE.

Topologies can be built up from TOPOLOGICAL BASES. For the REAL NUMBERS, the topology is the UNION of OPEN INTERVALS.

Toric Variety

Let $m_1, m_2, \ldots, m_n$ be distinct primitive elements of a 2-D LATTICE M such that $\det(m_i, m_{i+1}) > 0$ for $i = 1, \ldots, n$. Each collection $\Gamma = \{m_1, m_2, \ldots, m_n\}$ then forms a set of rays of a unique complete fan in M, and therefore determines a 2-D toric variety X_Γ.

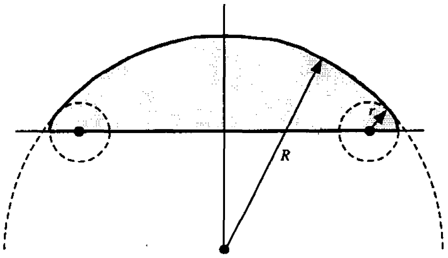
Torispherical Dome



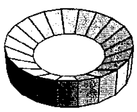
A torispherical dome is the surface obtained from the intersection of a SPHERICAL CAP with a tangent TORUS, as illustrated above. The radius of the sphere R is called the "crown radius," and the radius of the torus is called the "knuckle radius." Torispherical domes are used to construct pressure vessels.

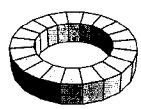
see also DOME, SPHERICAL CAP

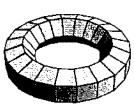
Torn Square Fractal

see CESÀRO FRACTAL

Toroid



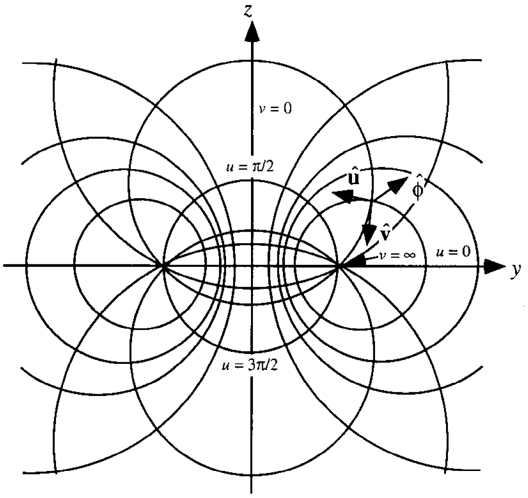




A SURFACE OF REVOLUTION obtained by rotating a closed PLANE CURVE about an axis parallel to the plane which does not intersect the curve. The simplest toroid is the TORUS.

see also PAPPUS'S CENTROID THEOREM, SURFACE OF REVOLUTION, TORUS

Toroidal Coordinates



A system of CURVILINEAR COORDINATES for which several different notations are commonly used. In this work $(u,\ v,\ \phi)$ is used, whereas Arfken (1970) uses $(\xi,\ \eta,\ \varphi)$. The toroidal coordinates are defined by

$$x = \frac{a\sinh v\cos\phi}{\cosh v - \cos u} \tag{1}$$

$$y = \frac{a\sinh v\sin\phi}{\cosh v - \cos u} \tag{2}$$

$$z = \frac{a\sin u}{\cosh v - \cos u}, \tag{3}$$

where $\sinh z$ is the HYPERBOLIC SINE and $\cosh z$ is the HYPERBOLIC COSINE. The SCALE FACTORS are

$$h_u = \frac{a}{\cosh v - \cos u} \tag{4}$$

$$h_v = \frac{a}{\cosh v - \cos u} \tag{5}$$

$$h_\phi = \frac{a\sinh v}{\cosh v - \cos u}. \tag{6}$$

The LAPLACIAN is

$$\begin{aligned}\nabla^2 f = {} & \frac{(\cosh v - \cos u)^3}{a^2}\frac{\partial}{\partial u}\left(\frac{1}{\cosh v - \cos u}\frac{\partial f}{\partial u}\right) \\ & + \frac{(\cosh v - \cos u)^3}{a^2\sinh v}\frac{\partial}{\partial v}\left(\frac{\sinh v}{\cosh v - \cos u}\frac{\partial f}{\partial v}\right) \\ & + \frac{(\cosh v - \cos u)^2}{a^2\sinh v}\frac{\partial^2 f}{\partial\phi^2} \qquad (7) \\ = {} & \left(\frac{-3\cos\coth^2 v + \cosh v\coth^2 v}{\cosh v - \cos u}\right. \\ & \left. + \frac{+3\cos^2 u\coth v\operatorname{csch} v - \cos^3 u\operatorname{csch}^2 v}{\cosh v - \cos u}\right)\frac{\partial^2}{\partial\phi^2} \\ & + (\cos u - \cosh v)\sin u\frac{\partial}{\partial u} + (\cosh v - \cos u)^2\frac{\partial^2}{\partial u^2} \\ & + (\cosh v - \cos u)(\cosh v\coth v - \sinh v \\ & - \cos u\coth v)\frac{\partial}{\partial v} + (\cosh^2 v - \cos u)^2\frac{\partial^2}{\partial v^2}. \qquad (8)\end{aligned}$$

The HELMHOLTZ DIFFERENTIAL EQUATION is not separable in toroidal coordinates, but LAPLACE'S EQUATION is.

Toroidal Field

A VECTOR FIELD resembling a TORUS which is purely circular about the z-AXIS of a SPHERE (i.e., follows lines of LATITUDE). A toroidal field takes the form

$$\mathbf{T} = \begin{bmatrix} 0 \\ \frac{1}{\sin\theta}\frac{\partial T}{\partial\phi} \\ -\frac{\partial T}{\partial\theta} \end{bmatrix}.$$

References

Stacey, F. D. *Physics of the Earth, 2nd ed.* New York: Wiley, p. 239, 1977.

Toroidal Function

A class of functions also called Ring Functions which appear in systems having toroidal symmetry. Toroidal functions can be expressed in terms of the Legendre Functions and Second Kinds (Abramowitz and Stegun 1972, p. 336):

$$P^{\mu}_{\nu-1/2}(\cosh\eta) = [\Gamma(1-\mu)]^{-1}2^{2\mu}(1-e^{-2\eta})^{-\mu}e^{-(\nu+1/2)\eta}$$
$$\times {}_2F_1(\tfrac{1}{2}-\mu, \tfrac{1}{2}+\nu-\mu; 1-2\mu; 1-e^{-2\eta})$$
$$P^{m}_{n-1/2}(\cosh\eta) = \frac{\Gamma(n+m+\frac{1}{2})(\sinh\eta)^m}{\Gamma(n-m+\frac{1}{2})2^m\sqrt{\pi}\,\Gamma(m+\frac{1}{2})}$$
$$\times \int_0^\pi \frac{sin^{2m}\phi\,d\phi}{(\cosh\eta+\cos\phi\sinh\eta)^{n+m+1/2}}$$
$$Q^{\mu}_{\nu-1/2}(\cosh\eta) = [\Gamma(1+\nu)]^{-1}\sqrt{\pi}\,e^{i\mu\pi}\Gamma(\tfrac{1}{2}+\nu+\mu)$$
$$\times (1-e^{-2\eta})^{\mu}e^{-(\nu+1/2)\eta}{}_2F_1(\tfrac{1}{2}-\mu, \tfrac{1}{2}+\nu+\mu; 1+\mu; 1-e^{-2\eta})$$
$$Q^{m}_{n-1/2}(\cosh\eta) = \frac{(-1)^m\Gamma(n+\frac{1}{2})}{\Gamma(n-m+\frac{1}{2})}$$
$$\times \int_0^\infty \frac{\cosh(mt)\,dt}{(\cosh\eta+\cosh t\sinh\eta)^{n+1/2}}$$

for $n > m$. Byerly (1959) identifies

$$\frac{1}{i^{n/2}}P^n_m(\coth x) = \operatorname{csch}^n x\frac{d^nP_m(\coth x)}{d(\coth x)^n}$$

as a Toroidal Harmonic.

Toroidal Harmonic

see Toroidal Function

Toroidal Polyhedron

A toroidal polyhedron is a Polyhedron with Genus $g \geq 1$ (i.e., having one or more Holes). Examples of toroidal polyhedra include the Császár Polyhedron and Szilassi Polyhedron, both of which have Genus 1 (i.e., the Topology of a Torus).

The only known Toroidal Polyhedron with no Diagonals is the Császár Polyhedron. If another exists, it must have 12 or more Vertices and Genus $g \geq 6$. The smallest known single-hole toroidal Polyhedron made up of only Equilateral Triangles is composed of 48 of them.

Torricelli Point

see Fermat Point

Torsion (Differential Geometry)

The rate of change of the Osculating Plane of a Space Curve. The torsion τ is Positive for a right-handed curve, and Negative for a left-handed curve. A curve with Curvature $\kappa \neq 0$ is planar Iff $\tau = 0$.

The torsion can be defined by

$$\tau \equiv -\mathbf{N}\cdot\mathbf{B}',$$

where $\mathbf{N}$ is the unit Normal Vector and $\mathbf{B}$ is the unit Binormal Vector. Written explicitly in terms of a parameterized Vector Function $\mathbf{x}$,

$$\tau = \frac{|\dot{\mathbf{x}}\,\ddot{\mathbf{x}}\,\dddot{\mathbf{x}}|}{\ddot{\mathbf{x}}\cdot\ddot{\mathbf{x}}} = \rho^2|\dot{\mathbf{x}}\,\ddot{\mathbf{x}}\,\dddot{\mathbf{x}}|,$$

where $|\mathbf{a}\,\mathbf{b}\,\mathbf{c}|$ denotes a Scalar Triple Product and ρ is the Radius of Curvature. The quantity $1/\tau$ is called the Radius of Torsion and is denoted σ or ϕ.

see also Curvature, Radius of Curvature, Radius of Torsion

Torsion (Group Theory)

If G is a GROUP, then the torsion elements Tor(G) of G (also called the torsion of G) are defined to be the set of elements g in G such that $g^n = e$ for some NATURAL NUMBER n, where e is the IDENTITY ELEMENT of the GROUP G.

In the case that G is ABELIAN, Tor(G) is a SUBGROUP and is called the torsion subgroup of G. If Tor(G) consists only of the IDENTITY ELEMENT, the GROUP G is called torsion-free.

see also ABELIAN GROUP, GROUP, IDENTITY ELEMENT

Torsion Number

One of a set of numbers defined in terms of an invariant generated by the finite cyclic covering spaces of a KNOT complement. The torsion numbers for KNOTS up to 9 crossings were cataloged by Reidemeister (1948).

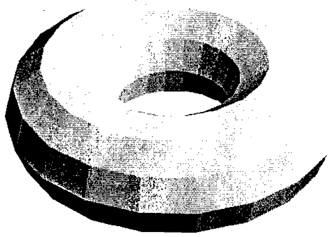
Torus



A torus is a surface having GENUS 1, and therefore possessing a single "HOLE." The usual torus in 3-D space is shaped like a donut, but the concept of the torus is extremely useful in higher dimensional space as well. One of the more common uses of n-D tori is in DYNAMICAL SYSTEMS. A fundamental result states that the PHASE SPACE trajectories of a HAMILTONIAN SYSTEM with n DEGREES OF FREEDOM and possessing n INTEGRALS OF MOTION lie on an n-D MANIFOLD which is topologically equivalent to an n-torus (Tabor 1989).

The usual 3-D "ring" torus is known in older literature as an "ANCHOR RING." Let the radius from the center of the hole to the center of the torus tube be c, and the radius of the tube be a. Then the equation in CARTESIAN COORDINATES is

$$(c - \sqrt{x^2 + y^2}\,)^2 + z^2 = a^2. \tag{1}$$

The parametric equations of a torus are

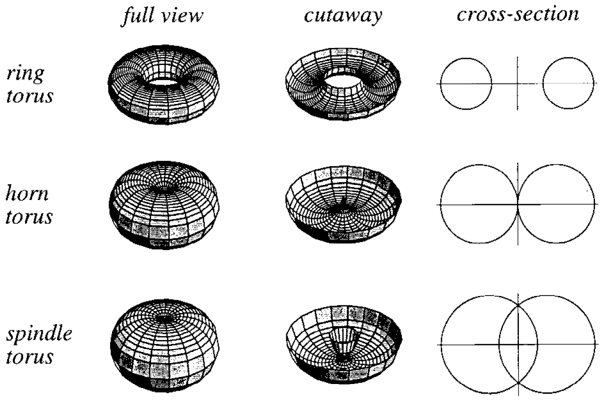
$$x = (c + a\cos v)\cos u \tag{2}$$

$$y = (c + a\cos v)\sin u \tag{3}$$

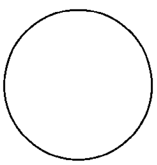
$$z = a\sin v \tag{4}$$

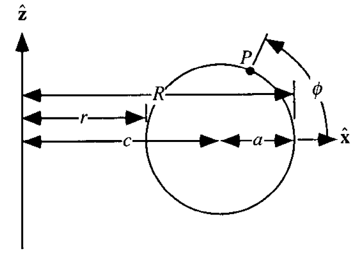
for $u, v \in [0, 2\pi)$. Three types of torus, known as the STANDARD TORI, are possible, depending on the relative sizes of a and c. $c > a$ corresponds to the RING TORUS (shown above), $c = a$ corresponds to a HORN TORUS which is tangent to itself at the point (0, 0, 0), and $c < a$ corresponds to a self-intersecting SPINDLE TORUS (Pinkall 1986).

If no specification is made, "torus" is taken to mean RING TORUS. The three STANDARD TORI are illustrated below, where the first image shows the full torus, the second a cut-away of the bottom half, and the third a CROSS-SECTION of a plane passing through the z-AXIS.



The STANDARD TORI and their inversions are CYCLIDES. If the coefficient of $\sin v$ in the formula for z is changed to $b \neq a$, an ELLIPTIC TORUS results.





To compute the metric properties of the ring torus, define the inner and outer radii by

$$r \equiv c - a \tag{5}$$

$$R \equiv c + a. \tag{6}$$

Solving for a and c gives

$$a = \tfrac{1}{2}(R - r) \tag{7}$$

$$c = \tfrac{1}{2}(R + r). \tag{8}$$

Then the SURFACE AREA of this torus is

$$S = (2\pi a)(2\pi c) = 4\pi^2 ac \tag{9}$$

$$= \pi^2 (R + r)(R - r), \tag{10}$$

and the VOLUME can be computed from PAPPUS'S CENTROID THEOREM

$$V = (\pi a^2)^2 \pi c = 2\pi^2 a^2 c \tag{11}$$

$$= \tfrac{1}{4}\pi^2 (R + r)(R - r)^2. \tag{12}$$

The coefficients of the first and second FUNDAMENTAL FORMS of the torus are given by

$$e = -(c + a\cos v)\cos v \tag{13}$$

$$f = 0 \tag{14}$$

$$g = -a \tag{15}$$

$$E = (c + a\cos v)^2 \tag{16}$$

$$F = 0 \tag{17}$$

$$G = a^2, \tag{18}$$

giving RIEMANNIAN METRIC

$$ds^2 = (c + a\cos v)^2\, du^2 + a^2\, dv^2, \tag{19}$$

AREA ELEMENT

$$dA = a(c + a\cos v)\, du \wedge dv \tag{20}$$

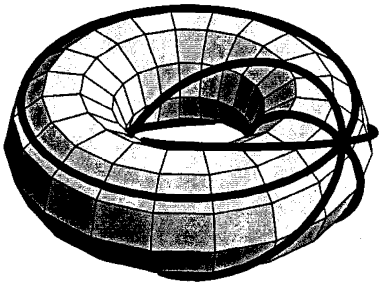
(where $du \wedge dv$ is a WEDGE PRODUCT), and GAUSSIAN and MEAN CURVATURES as

$$K = \frac{\cos v}{a(c + a\cos v)} \tag{21}$$

$$H = -\frac{c + 2a\cos v}{2a(c + a\cos v)} \tag{22}$$

(Gray 1993, pp. 289–291).

A torus with a HOLE in *its surface* can be turned inside out to yield an identical torus. A torus can be knotted externally or internally, but not both. These two cases are AMBIENT ISOTOPIES, but not REGULAR ISOTOPIES. There are therefore three possible ways of embedding a torus with zero or one KNOT.



An arbitrary point P on a torus (not lying in the xy-plane) can have four CIRCLES drawn through it. The first circle is in the plane of the torus and the second is PERPENDICULAR to it. The third and fourth CIRCLES are called VILLARCEAU CIRCLES (Villarceau 1848, Schmidt 1950, Coxeter 1969, Melnick 1983).

To see that two additional CIRCLES exist, consider a coordinate system with origin at the center of torus, with $\hat{\mathbf{z}}$ pointing up. Specify the position of P by its ANGLE ϕ measured around the tube of the torus. Define $\phi = 0$ for the circle of points farthest away from the center of the torus (i.e., the points with $x^2 + y^2 = R^2$), and draw the x-AXIS as the intersection of a plane through the z-axis and passing through P with the xy-plane. Rotate about the y-AXIS by an ANGLE θ, where

$$\theta = \sin^{-1}\left(\frac{a}{c}\right). \tag{23}$$

In terms of the old coordinates, the new coordinates are

$$x = x_1\cos\theta - z_1\sin\theta \tag{24}$$

$$z = x_1\sin\theta + z_1\cos\theta. \tag{25}$$

So in (x_1, y_1, z_1) coordinates, equation (1) of the torus becomes

$$[\sqrt{(x_1\cos\theta - z_1\sin\theta)^2 + y_1{}^2} - c]^2 + (x_1\sin\theta + z_1\cos\theta)^2 = a^2. \tag{26}$$

Squaring both sides gives

$$(x_1\cos\theta - z_1\sin\theta)^2 + y_1{}^2 + c^2 - 2c\sqrt{(x_1\cos\theta - z_1\sin\theta)^2 + y_1{}^2} + (x_1\sin\theta + z_1\cos\theta)^2 = a^2. \tag{27}$$

But

$$(x_1\cos\theta - z_1\sin\theta)^2 + (x_1\sin\theta + z_1\cos\theta)^2 = x_1{}^2 + z_1{}^2, \tag{28}$$

so

$$x_1{}^2 + y_1{}^2 + z_1{}^2 + c^2 - 2c\sqrt{(x_1\cos\theta - z_1\sin\theta)^2 + y_1{}^2} = a^2. \tag{29}$$

In the $z_1 = 0$ plane, plugging in (23) and factoring gives

$$[x_1{}^2 + (y_1 - a)^2 - c^2][x_1{}^2 + (y_1 + a) - c^2] = 0. \tag{30}$$

This gives the CIRCLES

$$x_1{}^2 + (y_1 - a)^2 = c^2 \tag{31}$$

and

$$x_1{}^2 + (y_1 + a)^2 = c^2 \tag{32}$$

in the z_1 plane. Written in MATRIX form with parameter $t \in [0, 2\pi)$, these are

$$C_1 = \begin{bmatrix} c\cos t \\ c\sin t + a \\ 0 \end{bmatrix} \tag{33}$$

$$C_2 = \begin{bmatrix} c\cos t \\ c\sin t - a \\ 0 \end{bmatrix}. \tag{34}$$

In the original (x, y, z) coordinates,

$$\begin{aligned} C_1 &= \begin{bmatrix} \cos\theta & 0 & -\sin\theta \\ 0 & 1 & 0 \\ -\sin\theta & 0 & \cos\theta \end{bmatrix} \begin{bmatrix} c\cos t \\ c\sin t + a \\ 0 \end{bmatrix} \\ &= \begin{bmatrix} c\cos\theta\cos t \\ c\sin t + a \\ -c\sin\theta\cos t \end{bmatrix} \end{aligned} \tag{35}$$

$$\begin{aligned} C_2 &= \begin{bmatrix} \cos\theta & 0 & \sin\theta \\ 0 & 1 & 0 \\ -\sin\theta & 0 & \cos\theta \end{bmatrix} \begin{bmatrix} c\cos t \\ c\sin t - a \\ 0 \end{bmatrix} \\ &= \begin{bmatrix} c\cos\theta\cos t \\ c\sin t - a \\ -c\sin\theta\cos t \end{bmatrix}. \end{aligned} \tag{36}$$

The point P must satisfy

$$z = a\sin\phi = c\sin\theta\cos t, \tag{37}$$

so

$$\cos t = \frac{a\sin\phi}{c\sin\theta}. \tag{38}$$

Plugging this in for x_1 and y_1 gives the ANGLE ψ by which the CIRCLE must be rotated about the z-AXIS in order to make it pass through P,

$$\psi = \tan^{-1}\left(\frac{y}{x}\right) = \frac{c\sin t + a}{c\cos\theta\cos t} = \frac{c\sqrt{1-\cos^2 t} + a}{c\cos\theta\cos t}. \tag{39}$$

The four CIRCLES passing through P are therefore

$$C_1 = \begin{bmatrix} \cos\psi & \sin\psi & 0 \\ -\sin\psi & \cos\psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} c\cos\theta\cos t \\ c\sin t + a \\ -c\sin\theta\cos t \end{bmatrix} \tag{40}$$

$$C_2 = \begin{bmatrix} \cos\psi & \sin\psi & 0 \\ -\sin\psi & \cos\psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} c\cos\theta\cos t \\ c\sin t - a \\ -c\sin\theta\cos t \end{bmatrix} \tag{41}$$

$$C_3 = \begin{bmatrix} (c + a\cos\phi)\cos t \\ (c + a\cos\phi)\sin t \\ a\sin\phi \end{bmatrix} \tag{42}$$

$$C_4 = \begin{bmatrix} c + a\cos t \\ 0 \\ a\sin t \end{bmatrix}. \tag{43}$$

Torus Coloring

The number of colors SUFFICIENT for MAP COLORING on a surface of GENUS g is given by the HEAWOOD CONJECTURE,

$$\chi(g) = \left\lfloor \tfrac{1}{2}\left(7 + \sqrt{48g + 1}\right) \right\rfloor,$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION. The fact that $\chi(g)$ (which is called the CHROMATIC NUMBER) is also NECESSARY was proved by Ringel and Youngs (1968) with two exceptions: the SPHERE (which requires the same number of colors as the PLANE) and the KLEIN BOTTLE. A g-holed TORUS therefore requires $\chi(g)$ colors. For $g = 0, 1, \ldots$, the first few values of $\chi(g)$ are 4, 7, 8, 9, 10, 11, 12, 12, 13, 13, 14, 15, 15, 16, ... (Sloane's A000934).

Torus Knot

A (p,q)-torus Knot is obtained by looping a string through the Hole of a Torus p times with q revolutions before joining its ends, where p and q are Relatively Prime. A (p,q)-torus knot is equivalent to a (q,p)-torus knot. The Crossing Number of a (p,q)-torus knot is

$$c = \min\{p(q-1), q(p-1)\} \tag{1}$$

(Murasugi 1991). The Unknotting Number of a (p,q)-torus knot is

$$u = \tfrac{1}{2}(p-1)(q-1) \tag{2}$$

(Adams 1991).

Torus knots with fewer than 11 crossings are the Trefoil Knot 03_{001} (3, 2), Solomon's Seal Knot 05_{001} (5, 2), 07_{001} (7, 2), 08_{019} (4, 3), 09_{001} (9, 2), and 10_{124} (5, 3) (Adams *et al.* 1991). The only Knots which are not Hyperbolic Knots are torus knots and Satellite Knots (including Composite Knots). The $(2,q)$, $(3,4)$, and $(3,5)$-torus knots are Almost Alternating Knots.

The Jones Polynomial of an (m,n)-Torus Knot is

$$\frac{t^{(m-1)(n-1)/2}(1-t^{m+1}-t^{n+1}+t^{m+n})}{1-t^2}. \tag{3}$$

The Bracket Polynomial for the torus knot $K_n = (2,n)$ is given by the Recurrence Relation

$$\langle K_n \rangle = A\langle K_{n-1}\rangle + (-1)^{n-1}A^{-3n+2}, \tag{4}$$

where

$$\langle K_1 \rangle = -A^3. \tag{5}$$

Total Angular Defect

see Descartes Total Angular Defect

Total Curvature

The total curvature of a curve is the quantity $\sqrt{\tau^2+\kappa^2}$, where τ is the Torsion and κ is the Curvature. The total curvature is also called the Third Curvature.

see also Curvature, Torsion (Differential Geometry)

Total Differential

see Exact Differential

Total Function

A Function defined for all possible input values.

Total Intersection Theorem

If one part of the total intersection group of a curve of order n with a curve of order $n_1 + n_2$ constitutes the total intersection with a curve of order n_1, then the other part will constitute the total intersection with a curve of order n_2.

References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, p. 32, 1959.

Total Order

A total order satisfies the conditions for a Partial Order plus the comparability condition. A Relation $\leq$ is a partial order on a Set S if

1. Reflexivity: $a \leq a$ for all $a \in S$
2. Antisymmetry: $a \leq b$ and $b \leq a$ implies $a = b$
3. Transitivity: $a \leq b$ and $b \leq c$ implies $a \leq c$,

and is a total order if, in addition,

4. Comparability: For any $a, b \in S$, either $a \leq b$ or $b \leq a$.

see also Partial Order, Relation

Total Space

The Space E of a Fiber Bundle given by the Map $f: E \to B$, where B is the Base Space of the Fiber Bundle.

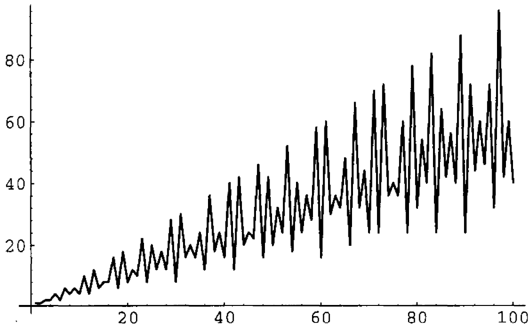
see also Base Space, Fiber Bundle, Space

Totative

A POSITIVE INTEGER less than or equal to a number n which is also RELATIVELY PRIME to n, where 1 is counted as being RELATIVELY PRIME to all numbers. The number of totatives of n is the value of the TOTIENT FUNCTION $\phi(n)$.

see also RELATIVELY PRIME, TOTIENT FUNCTION

Totient Function



The totient function $\phi(n)$, also called Euler's totient function, is defined as the number of POSITIVE INTEGERS $\leq n$ which are RELATIVELY PRIME to (i.e., do not contain any factor in common with) n, where 1 is counted as being RELATIVELY PRIME to all numbers. Since a number less than or equal to and RELATIVELY PRIME to a given number is called a TOTATIVE, the totient function $\phi(n)$ can be simply defined as the number of TOTATIVES of n. For example, there are eight TOTATIVES of 24 (1, 5, 7, 11, 13, 17, 19, and 23), so $\phi(24) = 8$.

By convention, $\phi(0) = 1$. The first few values of $\phi(n)$ for $n = 1, 2, \ldots$ are 1, 1, 2, 2, 4, 2, 6, 4, 6, 4, 10, ... (Sloane's A000010). $\phi(n)$ is plotted above for small n.

For a PRIME p,

$$\phi(p) = p - 1, \tag{1}$$

since all numbers less than p are RELATIVELY PRIME to p. If $m = p^\alpha$ is a POWER of a PRIME, then the numbers which have a common factor with m are the multiples of p: p, $2p$, ..., $(p^{\alpha-1})p$. There are $p^{\alpha-1}$ of these multiples, so the number of factors RELATIVELY PRIME to p^α is

$$\phi(p^\alpha) = p^\alpha - p^{\alpha-1} = p^{\alpha-1}(p-1) = p^\alpha\left(1 - \frac{1}{p}\right). \tag{2}$$

Now take a general m divisible by p. Let $\phi_p(m)$ be the number of POSITIVE INTEGERS $\leq m$ not DIVISIBLE by p. As before, p, $2p$, ..., $(m/p)p$ have common factors, so

$$\phi_p(m) = m - \frac{m}{p} = m\left(1 - \frac{1}{p}\right). \tag{3}$$

Now let q be some other PRIME dividing m. The INTEGERS divisible by q are q, $2q$, ..., $(m/q)q$. But these duplicate pq, $2pq$, ..., $(m/pq)pq$. So the number of terms which must be subtracted from ϕ_p to obtain ϕ_{pq} is

$$\Delta\phi_q(m) = \frac{m}{q} - \frac{m}{pq} = \frac{m}{q}\left(1 - \frac{1}{p}\right), \tag{4}$$

and

$$\begin{aligned}\phi_{pq}(m) &\equiv \phi_q(m) - \Delta\phi_q(m)\\ &= m\left(1 - \frac{1}{p}\right) - \frac{m}{q}\left(1 - \frac{1}{p}\right)\\ &= m\left(1 - \frac{1}{p}\right)\left(1 - \frac{1}{q}\right).\end{aligned} \tag{5}$$

By induction, the general case is then

$$\phi(n) = n\left(1 - \frac{1}{p_1}\right)\left(1 - \frac{1}{p_2}\right)\cdots\left(1 - \frac{1}{p_r}\right). \tag{6}$$

An interesting identity relates $\phi(n^2)$ to $\phi(n)$,

$$\phi(n^2) = n\phi(n). \tag{7}$$

Another identity relates the DIVISORS d of n to n via

$$\sum_d \phi(d) = n. \tag{8}$$

The DIVISOR FUNCTION satisfies the CONGRUENCE

$$n\sigma(n) \equiv 2 \pmod{\phi(n)} \tag{9}$$

for all PRIMES and no COMPOSITE with the exceptions of 4, 6, and 22 (Subbarao 1974), where $\sigma(n)$ is the DIVISOR FUNCTION. No COMPOSITE solution is currently known to

$$n - 1 \equiv 0 \pmod{\phi(n)} \tag{10}$$

(Honsberger 1976, p. 35).

Walfisz (1963), building on the work of others, showed that

$$\sum_{n=1}^N \phi(n) = \frac{3N^2}{\pi^2} + \mathcal{O}[N(\ln N)^{2/3}(\ln\ln N)^{4/3}], \tag{11}$$

and Landau (1900, quoted in Dickson 1952) showed that

$$\sum_{n=1}^N \frac{1}{\phi(n)} = A\ln N + B + \mathcal{O}\left(\frac{\ln N}{N}\right), \tag{12}$$

where

$$\begin{aligned}A &= \sum_{k=1}^\infty \frac{[\mu(k)]^2}{k\phi(k)} = \frac{\zeta(2)\zeta(3)}{\zeta(6)} = \frac{315}{2\pi^4}\zeta(3)\\ &= 1.9435964368\ldots\end{aligned} \tag{13}$$

$$\begin{aligned}B &= \gamma\frac{315}{2\pi^4}\zeta(3) - \sum_{k=1}^\infty \frac{[\mu(k)]^2\ln k}{k\phi(k)}\\ &= -0.0595536246\ldots,\end{aligned} \tag{14}$$

$\mu(k)$ is the MÖBIUS FUNCTION, $\zeta(z)$ is the RIEMANN ZETA FUNCTION, and γ is the EULER-MASCHERONI CONSTANT (Dickson). A can also be written

$$A = \prod_{k=1}^{\infty} \frac{1 - p_k{}^6}{(1 - p_k{}^{-2})(1 - p_k{}^{-3})} = \prod_{k=1}^{\infty} \left[1 + \frac{1}{p_k(p_k - 1)}\right]. \tag{15}$$

Note that this constant is similar to ARTIN'S CONSTANT.

If the GOLDBACH CONJECTURE is true, then for every number m, there are PRIMES p and q such that

$$\phi(p) + \phi(q) = 2m \tag{16}$$

(Guy 1994, p. 105).

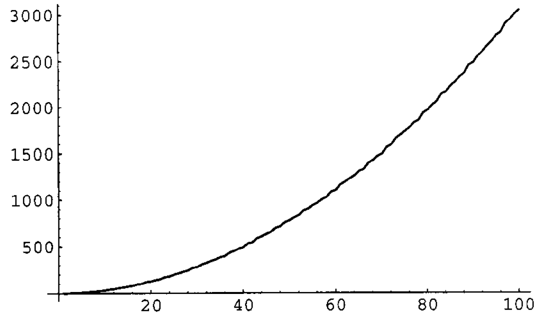
Curious equalities of consecutive values include

$$\phi(5186) = \phi(5187) = \phi(5188) = 2^5 3^4 \tag{17}$$

$$\phi(25930) = \phi(25935) = \phi(25940) = \phi(25942) = 2^7 3^4 \tag{18}$$

$$\phi(404471) = \phi(404473) = \phi(404477) = 2^8 3^2 5^2 7 \tag{19}$$

(Guy 1994, p. 91).



The SUMMATORY totient function, plotted above, is defined by

$$\Phi(n) \equiv \sum_{k=1}^{n} \phi(k) \tag{20}$$

and has the asymptotic series

$$\Phi(x) \sim \frac{1}{2\zeta(2)} x^2 + (x \ln x) \tag{21}$$

$$\sim \frac{3}{\pi^2} x^2 + \mathcal{O}(x \ln x), \tag{22}$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION (Perrot 1881). The first values of $\Phi(n)$ are 1, 2, 4, 6, 10, 12, 18, 22, 28, ... (Sloane's A002088).

Totient Function Constants

see SILVERMAN CONSTANT, TOTIENT FUNCTION

Totient Valence Function

$N_\phi(m)$ is the number of INTEGERS n for which $\phi(n) = m$, also called the MULTIPLICITY of m (Guy 1994). The table below lists values for $\phi(N) \leq 50$.

$\phi(N)$	m	N
1	2	1, 2
2	3	3, 4, 6
4	4	5, 8, 10, 12
6	4	7, 9, 14, 18
8	5	15, 16, 20, 24, 30
10	2	11, 22
12	6	13, 21, 26, 28, 36, 42
16	6	17, 32, 34, 40, 48, 60
18	4	19, 27, 38, 54
20	5	25, 33, 44, 50, 66
22	2	23, 46
24	10	35, 39, 45, 52, 56, 70, 72, 78, 84, 90
28	2	29, 58
30	2	31, 62
32	7	51, 64, 68, 80, 96, 102, 120
36	8	37, 57, 63, 74, 76, 108, 114, 126
40	9	41, 55, 75, 82, 88, 100, 110, 132, 150
42	4	43, 49, 86, 98
44	3	69, 92, 138
46	2	47, 94
48	11	65, 104, 105, 112, 130, 140, 144, 156, 168, 180, 210

A table listing the first value of $\phi(N)$ with multiplicities up to 100 follows (Sloane's A014573).

M	ϕ	M	ϕ	M	ϕ	M	ϕ
0	3	26	2560	51	4992	76	21840
2	1	27	384	52	17640	77	9072
3	2	28	288	53	2016	78	38640
4	4	29	1320	54	1152	79	9360
5	8	30	3696	55	6000	80	81216
6	12	31	240	56	12288	81	4032
7	32	32	768	57	4752	82	5280
8	36	33	9000	58	2688	83	4800
9	40	34	432	59	3024	84	4608
10	24	35	7128	60	13680	85	16896
11	48	36	4200	61	9984	86	3456
12	160	37	480	62	1728	87	3840
13	396	38	576	63	1920	88	10800
14	2268	39	1296	64	2400	89	9504
15	704	40	1200	65	7560	90	18000
16	312	41	15936	66	2304	91	23520
17	72	42	3312	67	22848	92	39936
18	336	43	3072	68	8400	93	5040
19	216	44	3240	69	29160	94	26208
20	936	45	864	70	5376	95	27360
21	144	46	3120	71	3360	96	6480
22	624	47	7344	72	1440	97	9216
23	1056	48	3888	73	13248	98	2880
24	1760	49	720	74	11040	99	26496
25	360	50	1680	75	27720	100	34272

It is thought that $N_\phi(m) \geq 2$ (i.e., the totient valence function never takes on the value 1), but this has not been proven. This assertion is called CARMICHAEL'S TOTIENT FUNCTION CONJECTURE and is equivalent to the statement that for all n, there exists $m \neq n$ such that $\phi(n) = \phi(m)$ (Ribenboim 1996, pp. 39–40). Any counterexample must have more than 10,000,000 DIGITS (Schlafly and Wagon 1994, Conway and Guy 1996).

Tournament Matrix

A matrix for a round-robin tournament involving n players competing in $n(n-1)/2$ matches (no ties allowed) having entries

$$a_{ij} = \begin{cases} 1 & \text{if player } i \text{ defeats player } j \\ -1 & \text{if player } i \text{ loses to player } j \\ 0 & \text{if } i = j. \end{cases}$$

The MATRIX satisfies

$$\mathsf{A} + \mathsf{A}^{\mathrm{T}} + \mathsf{I} = \mathsf{J},$$

where I is the IDENTITY MATRIX, J is an $n \times n$ MATRIX of all 1s, and A^{T} is the MATRIX TRANSPOSE of A.

The tournament matrix for n players has zero DETERMINANT IFF n is ODD (McCarthy and Benjamin 1996). The dimension of the NULLSPACE of an n-player tournament matrix is

$$\dim[\text{nullspace}] = \begin{cases} 0 & \text{for } n \text{ even} \\ 1 & \text{for } n \text{ odd} \end{cases}$$

(McCarthy 1996).

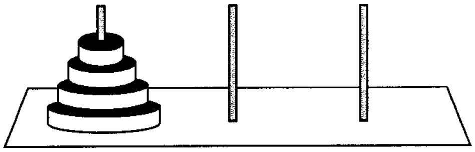
Tower of Power

see POWER TOWER

Towers of Hanoi



A PUZZLE invented by E. Lucas in 1883. Given a stack of n disks arranged from largest on the bottom to smallest on top placed on a rod, together with two empty rods, the towers of Hanoi puzzle asks for the minimum number of moves required to reverse the order of the stack (where moves are allowed only if they place smaller disks on top of larger disks). The problem is ISOMORPHIC to finding a HAMILTONIAN PATH on an n-HYPERCUBE.

For n disks, the number of moves h_n required is given by the RECURRENCE RELATION

$$h_n = 2h_{n-1} + 1.$$

Solving gives

$$h_n = 2^n - 1.$$

The number of disks moved after the kth step is the same as the element which needs to be added or deleted in the kth ADDEND of the RYSER FORMULA (Gardner 1988, Vardi 1991).

A HANOI GRAPH can be constructed whose VERTICES correspond to legal configurations of n towers of Hanoi, where the VERTICES are adjacent if the corresponding configurations can be obtained by a legal move. It can be solved using a binary GRAY CODE.

Poole (1994) gives *Mathematica*® (Wolfram Research, Champaign, IL) routines for solving an arbitrary disk configuration in the fewest possible moves. The proof of minimality is achieved using the LUCAS CORRESPONDENCE which relates PASCAL'S TRIANGLE to the HANOI GRAPH. ALGORITHMS are known for transferring disks for four pegs, but none has been proved minimal. For additional references, see Poole (1994).

Trace (Complex)

The image of the path γ in $\mathbb{C}$ under the FUNCTION f is called the trace. This term is unrelated to that applied to MATRICES and TENSORS.

Trace (Group)

see CHARACTER (GROUP)

Trace (Map)

Let a PATCH be given by the map $\mathbf{x} : U \to \mathbb{R}^n$, where U is an open subset of $\mathbb{R}^2$, or more generally by $\mathbf{x} : A \to \mathbb{R}^n$, where A is any SUBSET of $\mathbb{R}^2$. Then $\mathbf{x}(U)$ (or more generally, $\mathbf{x}(A)$) is called the trace of $\mathbf{x}$.

see also PATCH

References

Gray, A. *Modern Differential Geometry of Curves and Surfaces.* Boca Raton, FL: CRC Press, pp. 183–184, 1993.

Trace (Matrix)

The trace of an $n \times n$ SQUARE MATRIX A is defined by

$$\operatorname{Tr}(\mathsf{A}) \equiv a_{ii}, \tag{1}$$

where EINSTEIN SUMMATION is used (i.e., the a_{ii} is summed over $i = 1, \ldots, n$). For SQUARE MATRICES A and B, it is true that

$$\operatorname{Tr}(\mathsf{A}) = \operatorname{Tr}(\mathsf{A}^{\mathrm{T}}) \tag{2}$$

$$\operatorname{Tr}(\mathsf{A} + \mathsf{B}) = \operatorname{Tr}(\mathsf{A}) + \operatorname{Tr}(\mathsf{B}) \tag{3}$$

$$\operatorname{Tr}(\alpha\mathsf{A}) = \alpha \operatorname{Tr}(\mathsf{A}) \tag{4}$$

(Lange 1987, p. 40). The trace is invariant under a SIMILARITY TRANSFORMATION

$$\mathsf{A}' \equiv \mathsf{BAB}^{-1} \tag{5}$$

(Lange 1987, p. 64). Since

$$(bab^{-1})_{ij} = b_{il}a_{lk}b^{-1}_{kj}, \tag{6}$$

$$\begin{aligned}\mathrm{Tr}(\mathsf{BAB}^{-1}) &= b_{il}a_{lk}b^{-1}{}_{ki} \\ &= (b^{-1}b)_{kl}a_{lk} = \delta_{kl}a_{lk} \\ &= a_{kk} = \mathrm{Tr}(\mathsf{A}),\end{aligned} \tag{7}$$

where δ_{ij} is the KRONECKER DELTA.

The trace of a product of square matrices is independent of the order of the multiplication since

$$\begin{aligned}\mathrm{Tr}(\mathsf{AB}) &= (ab)_{ii} = a_{ij}b_{ji} = b_{ji}a_{ij} \\ &= (ba)_{jj} = \mathrm{Tr}(\mathsf{BA}).\end{aligned} \tag{8}$$

Therefore, the trace of the COMMUTATOR of A and B is given by

$$\mathrm{Tr}([\mathsf{A},\mathsf{B}]) \equiv \mathrm{Tr}(\mathsf{AB}) - \mathrm{Tr}(\mathsf{BA}) = 0. \tag{9}$$

The product of a SYMMETRIC and an ANTISYMMETRIC MATRIX has zero trace,

$$\mathrm{Tr}(A_S B_A) = 0. \tag{10}$$

The value of the trace can be found using the fact that the matrix can always be transformed to a coordinate system where the z-AXIS lies along the axis of rotation. In the new coordinate system, the MATRIX is

$$\mathsf{A}' = \begin{bmatrix} \cos\phi & \sin\phi & 0 \\ -\sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{bmatrix}, \tag{11}$$

so the trace is

$$\mathrm{Tr}(\mathsf{A}') = \mathrm{Tr}(\mathsf{A}) \equiv a_{ii} = 1 + 2\cos\phi. \tag{12}$$

References

Lang, S. *Linear Algebra, 3rd ed.* New York: Springer-Verlag, pp. 40 and 64, 1987.

Trace (Tensor)

The trace of a second-RANK TENSOR T is a SCALAR given by the CONTRACTED mixed TENSOR equal to T_i^i. The trace satisfies

$$\mathrm{Tr}\left[M^{-1}(x)\frac{\partial}{\partial x^\lambda}M(x)\right] = \frac{\partial}{\partial x^\lambda}\ln[\det(x)],$$

and

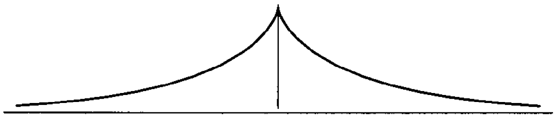
$$\begin{aligned}\delta\ln[\det M] &= \ln[\det(M+\delta M)] - \ln(\det M) \\ &= \ln\left[\frac{\det(M+\delta M)}{\det M}\right] \\ &= \ln[\det M^{-1}(M+\delta M)] \\ &= \ln[\det(1+M^{-1}\delta M)] \\ &\approx \ln[1+\mathrm{Tr}(M^{-1}\delta M)] \\ &\approx \mathrm{Tr}(M^{-1}\delta M).\end{aligned}$$

see also CONTRACTION (TENSOR)

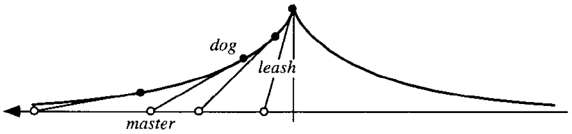
Tractory

see TRACTRIX

Tractrix



The tractrix is the CATENARY INVOLUTE described by a point initially on the vertex. It has a constant NEGATIVE CURVATURE and is sometimes called the TRACTORY or EQUITANGENTIAL CURVE. The tractrix was first studied by Huygens in 1692, who gave it the name "tractrix." Later, Leibniz, Johann Bernoulli, and others studied the curve.



The tractrix arises from the following problem posed to Leibniz: What is the path of an object starting off with a vertical offset when it is dragged along by a string of constant length being pulled along a straight horizontal line? By associating the object with a dog, the string with a leash, and the pull along a horizontal line with the dog's master, the curve has the descriptive name HUNDKURVE (hound curve) in German. Leibniz found the curve using the fact that the axis is an asymptote to the tractrix (MacTutor Archive).

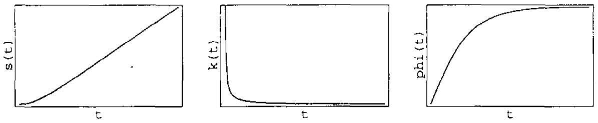
In CARTESIAN COORDINATES the tractrix has equation

$$x = a\,\mathrm{sech}^{-1}\left(\frac{y}{a}\right) - \sqrt{a^2-y^2}. \tag{1}$$

One parametric form is

$$x(t) = a(t - \tanh t) \tag{2}$$

$$y(t) = a \operatorname{sech} t. \tag{3}$$



The Arc Length, Curvature, and Tangential Angle are

$$s(t) = \ln(\cosh t) \tag{4}$$

$$\kappa(t) = \operatorname{csch} t \tag{5}$$

$$\phi(t) = 2\tan^{-1}[\tanh(\tfrac{1}{2}t)]. \tag{6}$$

A second parametric form in terms of the Angle ϕ of the straight line tangent to the tractrix is

$$x = a\{\ln[\tan(\tfrac{1}{2}\phi)] + \cos\phi\} \tag{7}$$

$$y = a\sin\phi \tag{8}$$

(Gray 1993). This parameterization has Curvature

$$\kappa(\phi) = |\tan\phi|. \tag{9}$$

A parameterization which traverses the tractrix with constant speed a is given by

$$x(t) = \begin{cases} ae^{-v/a} & \text{for } v \in [0,\infty) \\ ae^{v/a} & \text{for } v \in (-\infty, 0] \end{cases} \tag{10}$$

$$y(t) = \begin{cases} a[\tanh^{-1}(\sqrt{1-e^{-2v/a}}\,) - \sqrt{1-e^{-2v/a}}] & \text{for } v \in [0,\infty) \\ a[-\tanh^{-1}(\sqrt{1-e^{2v/a}}\,) + \sqrt{1-e^{2v/a}}] & \text{for } v \in (-\infty, 0]. \end{cases} \tag{11}$$

When a tractrix is rotated around its asymptote, a Pseudosphere results. This is a surface of constant Negative Curvature. For a tractrix, the length of a Tangent from its point of contact to an asymptote is constant. The Area between the tractrix and its asymptote is finite.

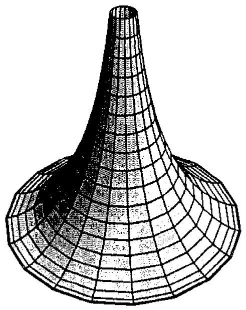
Tractrix Evolute

The Evolute of the Tractrix is the Catenary.

Tractrix Radial Curve

The Radial Curve of the Tractrix is the Kappa Curve.

Tractroid



The Surface of Revolution produced by revolving the Tractrix

$$x = \operatorname{sech} u \tag{1}$$

$$z = u - \tanh u \tag{2}$$

about the z-Axis is a tractroid given by

$$x = \operatorname{sech} u \cos v \tag{3}$$

$$y = \operatorname{sech} u \sin v \tag{4}$$

$$z = u - \tanh u. \tag{5}$$

see also Pseudosphere, Surface of Revolution, Tractrix

Transcendental Curve

A curve which intersects some straight line in an infinity of points (but for which not every point lies on this curve).

References
Borwein, J. M.; Borwein, P. B.; and Bailey, D. H. "Ramanujan, Modular Equations, and Approximations to Pi or How to Compute One Billion Digits of Pi." *Amer. Math. Monthly* **96**, 201–219, 1989.

Transcendental Equation

An equation or formula involving Transcendental Functions.

Transcendental Function

A function which "transcends," i.e., cannot be expressed in terms of, the usual Elementary Functions. Define

$$\begin{aligned} l_1(z) &\equiv l(z) \equiv \ln(z) \\ e_1(z) &\equiv e(z) \equiv e^z \\ \varsigma_1 f(z) &\equiv \varsigma f(z) \equiv \int f(z)\,dz, \end{aligned}$$

and let $l_2 \equiv l(l(z))$, etc. These are called the "elementary" transcendental functions (Watson 1966, p. 111).

see also Algebraic Function, Elementary Function

References

Watson, G. N. *A Treatise on the Theory of Bessel Functions, 2nd ed.* Cambridge, England: Cambridge University Press, 1966.

Transcendental Number

A number which is not the Root of *any* Polynomial equation with Integer Coefficients, meaning that it not an Algebraic Number of any degree, is said to be transcendental. This definition guarantees that every transcendental number must also be Irrational, since a Rational Number is, by definition, an Algebraic Number of degree one.

Transcendental numbers are important in the history of mathematics because their investigation provided the first proof that Circle Squaring, one of the Geometric Problems of Antiquity which had baffled mathematicians for more than 2000 years was, in fact, insoluble. Specifically, in order for a number to be produced by a Geometric Construction using the ancient Greek rules, it must be either Rational or a very special kind of Algebraic Number known as a Euclidean Number. Because the number π is transcendental, the construction cannot be done according to the Greek rules.

Georg Cantor was the first to prove the Existence of transcendental numbers. Liouville subsequently showed how to construct special cases (such as Liouville's Constant) using Liouville's Rational Approximation Theorem. In particular, he showed that any number which has a rapidly converging sequence of rational approximations must be transcendental. For many years, it was only known how to determine if special classes of numbers were transcendental. The determination of the status of more general numbers was considered an important enough unsolved problem that it was one of Hilbert's Problems.

Great progress was subsequently made by Gelfond's Theorem, which gives a general rule for determining if special cases of numbers of the form α^β are transcendental. Baker produced a further revolution by proving the transcendence of sums of numbers of the form $\alpha \ln \beta$ for Algebraic Numbers α and β.

The number e was proven to be transcendental by Hermite in 1873, and Pi (π) by Lindemann in 1882. e^π is transcendental by Gelfond's Theorem since

$$(-1)^{-i} = (e^{i\pi})^{-i} = e^\pi.$$

The Gelfond-Schneider Constant $2^{\sqrt{2}}$ is also transcendental. Other known transcendentals are $\sin 1$ where $\sin x$ is the Sine function, $J_0(1)$ where $J_0(x)$ is a Bessel Function of the First Kind (Hardy and Wright 1985), $\ln 2$, $\ln 3/\ln 2$, the first zero $x_0 = 2.4048255\ldots$ of the Bessel Function $J_0(x_0)$ (Le Lionnais 1983, p. 46), $\pi + \ln 2 + \sqrt{2}\ln 3$ (Borwein *et al.* 1989), the Thue-Morse Constant $P = 0.4124540336\ldots$ (Dekking 1977, Allouche and Shallit), the Champernowne Constant $0.1234567891011\ldots$, the Thue Constant

$$0.110110111110110111110110110\ldots,$$

$\Gamma(\frac{1}{3})$ (Le Lionnais 1983, p. 46), $\Gamma(\frac{1}{4})\pi^{-1/4}$ (Davis 1959), and $\Gamma(\frac{1}{4})$ (Chudnovsky, Waldschmidt), where $\Gamma(x)$ is the Gamma Function. At least one of πe and $\pi + e$ (and probably both) are transcendental, but transcendence has not been proven for either number on its own.

It is not known if e^e, π^π, π^e, γ (the Euler-Mascheroni Constant), $I_0(2)$, or $I_1(2)$ (where $I_n(x)$ is a Modified Bessel Function of the First Kind) are transcendental.

The "degree" of transcendence of a number can be characterized by a so-called Liouville-Roth Constant. There are still many fundamental and outstanding problems in transcendental number theory, including the Constant Problem and Schanuel's Conjecture.

see also Algebraic Number, Constant Problem, Gelfond's Theorem, Irrational Number, Lindemann-Weierstraß Theorem, Liouville-Roth Constant, Roth's Theorem, Schanuel's Conjecture, Thue-Siegel-Roth Theorem

Transcritical Bifurcation

Let $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ be a one-parameter family of C^2 maps satisfying

$$f(0,\mu) = 0 \tag{1}$$

$$\left[\frac{\partial f}{\partial x}\right]_{\mu=0,x=0} = 1 \tag{2}$$

$$\left[\frac{\partial f}{\partial x}\right]_{\mu,x} = \left[\frac{\partial f}{\partial x}\right]_{\mu=0,x=\mu} \tag{3}$$

$$\left[\frac{\partial^2 f}{\partial x \partial \mu}\right]_{0,0} > 0 \tag{4}$$

$$\left[\frac{\partial^2 f}{\partial \mu^2}\right]_{\mu=0,x=0} > 0. \tag{5}$$

Then there are two branches, one stable and one unstable. This BIFURCATION is called a transcritical bifurcation. An example of an equation displaying a transcritical bifurcation is

$$\dot{x} = \mu x - x^2. \tag{6}$$

(Guckenheimer and Holmes 1997, p. 145).

see also BIFURCATION

Transfer Function

The engineering terminology for one use of FOURIER TRANSFORMS. By breaking up a wave pulse into its frequency spectrum

$$f_\nu = F(\nu)e^{2\pi i\nu t}, \tag{1}$$

the entire signal can be written as a sum of contributions from each frequency,

$$f(t) = \int_{-\infty}^{\infty} f_\nu \, d\nu = \int_{-\infty}^{\infty} F(\nu)e^{2\pi i\nu t} \, d\nu. \tag{2}$$

If the signal is modified in some way, it will become

$$g_\nu(t) = \phi(\nu)f_\nu(t) = \phi(\nu)F(\nu)e^{2\pi i\nu t} \tag{3}$$

$$g(t) = \int_{-\infty}^{\infty} g_\nu(t)\, dt = \int_{-\infty}^{\infty} \phi(\nu)F(\nu)e^{2\pi i\nu t} \, d\nu, \tag{4}$$

where $\phi(\nu)$ is known as the "transfer function." FOURIER TRANSFORMING ϕ and F,

$$\phi(\nu) = \int_{-\infty}^{\infty} \Phi(t)e^{-2\pi i\nu t} \, dt \tag{5}$$

$$F(\nu) = \int_{-\infty}^{\infty} f(t)e^{-2\pi i\nu t} \, dt. \tag{6}$$

From the CONVOLUTION THEOREM,

$$g(t) = f(t) * \Phi(t) = \int_{-\infty}^{\infty} f(t)\Phi(t-\tau)\, d\tau. \tag{7}$$

see also CONVOLUTION THEOREM, FOURIER TRANSFORM

Transfinite Diameter

Let

$$\phi(z) = cz + c_0 + c_1 z^{-1} + c_2 z^{-2} + \ldots$$

be an ANALYTIC FUNCTION, REGULAR and UNIVALENT for $|z| > 1$, which maps $|z| > 1$ CONFORMALLY onto the region T preserving the POINT AT INFINITY and its direction. Then the function $\phi(z)$ is uniquely determined and c is called the transfinite diameter, sometimes also known as ROBIN'S CONSTANT or the CAPACITY of $\phi(z)$.

see also ANALYTIC FUNCTION, REGULAR FUNCTION, UNIVALENT FUNCTION

Transfinite Number

One of Cantor's ORDINAL NUMBERS ω, $\omega+1$, $\omega+2$, ..., $\omega+\omega$, $\omega+\omega+1$, ... which is "larger" than any WHOLE NUMBER.

see also $\aleph_0$, $\aleph_1$, CARDINAL NUMBER, CONTINUUM, ORDINAL NUMBER, WHOLE NUMBER

Transform

A shortened term for INTEGRAL TRANSFORM.

Geometrically, if S and T are two transformations, then the SIMILARITY TRANSFORMATION TST^{-1} is sometimes called the transform (Woods 1961).

Transformation

see Function, Map

Transitive

A Relation R on a Set S is transitive provided that for all x, y and z in S such that xRy and yRz, we also have xRz.

see also Associative, Commutative, Relation

Transitive Closure

The transitive closure of a binary Relation R on a Set X is the minimal Transitive relation R' on X that contains R. Thus $aR'b$ for any elements a and b of X, provided either that aRb or that there exists some element c of X such that aRc and cRb.

see also Reflexive Closure, Transitive Reduction

Transitive Reduction

The transitive reduction of a binary Relation R on a Set X is the minimum relation R' on X with the same Transitive Closure as R. Thus $aR'b$ for any elements a and b of X, provided that aRb and there exists no element c of X such that aRc and cRb.

see also Reflexive Reduction, Transitive Closure

Transitivity Class

Let $S(T)$ be the group of symmetries which map a Monohedral Tiling T onto itself. The Transitivity Class of a given tile T is then the collection of all tiles to which T can be mapped by one of the symmetries of $S(T)$.

see also Monohedral Tiling

References

References
Beyer, W. H. (Ed.) *CRC Standard Mathematical Tables, 28th ed.* Boca Raton, FL: CRC Press, p. 211, 1987.

Translation Relation

A mathematical relationship transforming a function $f(x)$ to the form $f(x+a)$.

see also Argument Addition Relation, Argument Multiplication Relation, Recurrence Relation, Reflection Relation

Transpose

The object obtained by replacing all elements a_{ij} with a_{ji}. For a second-Rank Tensor a_{ij}, the tensor transpose is simply a_{ji}. The matrix transpose, written A^{T}, is the Matrix obtained by exchanging A's rows and columns, and satisfies the identity

$$(\mathsf{A}^{\mathrm{T}})^{-1} = (\mathsf{A}^{-1})^{\mathrm{T}}.$$

The product of two transposes satisfies

$$(\mathsf{B}^{\mathrm{T}}\mathsf{A}^{\mathrm{T}})_{ij} = (b^{\mathrm{T}})_{ik}(a^{\mathrm{T}})_{kj} = b_{ki}a_{jk} = a_{jk}b_{ki} = (\mathsf{AB})_{ji}$$
$$= (\mathsf{AB})^{\mathrm{T}}_{ij}.$$

Therefore,

$$(\mathsf{AB})^{\mathrm{T}} = \mathsf{B}^{\mathrm{T}}\mathsf{A}^{\mathrm{T}}.$$

Transpose Map

see Pullback Map

Transposition

An exchange of two elements of a Set with all others staying the same. A transposition is therefore a Permutation of two elements. For example, the swapping of 2 and 5 to take the list 123456 to 153426 is a transposition.

see also Permutation, Transposition Order

Transposition Group

A Permutation Group in which the Permutations are limited to Transpositions.

see also Permutation Group

Transposition Order

An ordering of PERMUTATIONS in which each two adjacent permutations differ by the TRANSPOSITION of two elements. For the permutations of $\{1, 2, 3\}$ there are two listings which are in transposition order. One is 123, 132, 312, 321, 231, 213, and the other is 123, 321, 312, 213, 231, 132.

see also LEXICOGRAPHIC ORDER, PERMUTATION

Transversal Array

A set of n cells in an $n \times n$ SQUARE such that no two come from the same row and no two come from the same column. The number of transversals of an $n \times n$ SQUARE is $n!$ (n FACTORIAL).

Transversal Design

A transversal design $\mathrm{TD}_\lambda(k, n)$ of order n, block size k, and index λ is a triple (V, G, B) such that

1. V is a set of kn elements,
2. G is a partition of V into k classes, each of size n (the "groups"),
3. B is a collection of k-subsets of V (the "blocks"), and
4. Every unordered pair of elements from V is contained in either exactly one group or in exactly λ blocks, but not both.

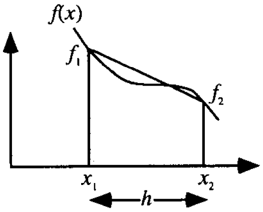
Trapezoidal Rule



The 2-point NEWTON-COTES FORMULA

$$\int_{x_1}^{x_2} f(x)\,dx = \tfrac{1}{2}h(f_1+f_2) - \tfrac{1}{2}h^3 f''(\xi),$$

where $f_i \equiv f(x_i)$, h is the separation between the points, and ξ is a point satisfying $x_1 \le \xi \le x_2$. Picking ξ to maximize $f''(\xi)$ gives an upper bound for the error in the trapezoidal approximation to the INTEGRAL.

Traveling Salesman Constants

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Let $L(n,d)$ be the smallest TOUR length for n points in a d-D HYPERCUBE. Then there exists a smallest constant $\alpha(d)$ such that for all optimal TOURS in the HYPERCUBE,

$$\limsup_{n\to\infty} \frac{L(n,d)}{n^{(d-1)/d}\sqrt{d}} \le \alpha(d), \tag{1}$$

and a constant $\beta(d)$ such that for *almost* all optimal tours in the HYPERCUBE,

$$\lim_{n\to\infty} \frac{L(n,d)}{n^{(d-1)/d}\sqrt{d}} = \beta(d). \tag{2}$$

These constants satisfy the inequalities

$$\begin{aligned} 0.44194 < \gamma_2 = \tfrac{5}{16}\sqrt{2} \le \beta(2) \\ \le \delta < 0.6508 < 0.75983 < 3^{-1/4} \le \alpha(2) \\ \le \phi < 0.98398 \end{aligned} \tag{3}$$

$$\begin{aligned} 0.37313 < \gamma_3 \le \beta(3) \le 12^{1/6}6^{-1/2} < 0.61772 < 0.64805 \\ < 2^{1/6}3^{-1/2} \le \alpha(3) \le 0.90422 \end{aligned} \tag{4}$$

$$\begin{aligned} 0.34207 < \gamma_4 \le \beta(4) \le 12^{1/8}6^{-1/2} < 0.55696 \\ < 0.59460 < 2^{-3/4} \le \alpha(4) \le 0.8364 \end{aligned} \tag{5}$$

(Fejes Tóth 1940, Verblunsky 1951, Few 1955, Beardwood *et al.* 1959), where

$$\gamma_d \equiv \frac{\Gamma\left(3+\frac{1}{d}\right)\left[\Gamma(\frac{1}{2}d+1)\right]^{1/d}}{2\sqrt{\pi}(d^{1/2}+d^{-1/2})}, \tag{6}$$

$\Gamma(z)$ is the GAMMA FUNCTION, δ is an expression involving STRUVE FUNCTIONS and NEUMANN FUNCTIONS,

$$\phi \equiv \frac{280(3-\sqrt{3})}{840-280\sqrt{3}+4\sqrt{5}-\sqrt{10}} \tag{7}$$

(Karloff 1989), and

$$\psi \equiv \tfrac{1}{2}3^{-2/3}(4+\ln 3)^{2/3} \tag{8}$$

(Goddyn 1990). In the LIMIT $d\to\infty$,

$$\begin{aligned} 0.24197 < \lim_{d\to\infty}\gamma_d = \frac{1}{\sqrt{2\pi e}} \le \liminf_{d\to\infty}\beta(d) \\ \le \limsup_{d\to\infty}\beta(d) \le \lim_{d\to\infty} 12^{1/(2d)}6^{-1/2} \\ = \frac{1}{\sqrt{6}} < 0.40825 \end{aligned} \tag{9}$$

and

$$\begin{aligned} 0.24197 < \frac{1}{\sqrt{2\pi e}} \le \lim_{d\to\infty}\alpha(d) \\ \le \frac{2(3-\sqrt{3})\theta}{\sqrt{2\pi e}} < 0.4052, \end{aligned} \tag{10}$$

where

$$\tfrac{1}{2} \le \theta = \lim_{d\to\infty}[\theta(d)]^{1/d} \le 0.6602, \tag{11}$$

and $\theta(d)$ is the best SPHERE PACKING density in d-D space (Goddyn 1990, Moran 1984, Kabatyanskii and Levenshtein 1978). Steele and Snyder (1989) proved that the limit $\alpha(d)$ exists.

Now consider the constant

$$\kappa \equiv \lim_{n\to\infty}\frac{L(n,2)}{\sqrt{n}} = \beta(2)\sqrt{2}, \tag{12}$$

so

$$\tfrac{5}{8} = \gamma_2\sqrt{2} \le \kappa \le \delta\sqrt{2} < 0.9204. \tag{13}$$

The best current estimate is $\kappa \approx 0.7124$.

A certain self-avoiding SPACE-FILLING CURVE is an optimal TOUR through a set of n points, where n can be arbitrarily large. It has length

$$\lambda \equiv \lim_{m\to\infty}\frac{L_m}{\sqrt{n_m}} = \frac{4(1+2\sqrt{2})\sqrt{51}}{153} = 0.7147827\ldots, \tag{14}$$

where L_m is the length of the curve at the mth iteration and n_m is the point-set size (Moscato and Norman).

Trawler Problem

A fast boat is overtaking a slower one when fog suddenly sets in. At this point, the boat being pursued changes course, but not speed. How should the pursuing vessel proceed in order to be sure of catching the other boat?

The amazing answer is that the pursuing boat should continue to the point where the slow boat would be if it had set its course directly for the pursuing boat when the fog set in. If the boat is not there, it should proceed in a SPIRAL whose origin is the point where the slow boat was when the fog set in. The SPIRAL can be constructed in such a way that the two boats will intersect before a complete turn is made.

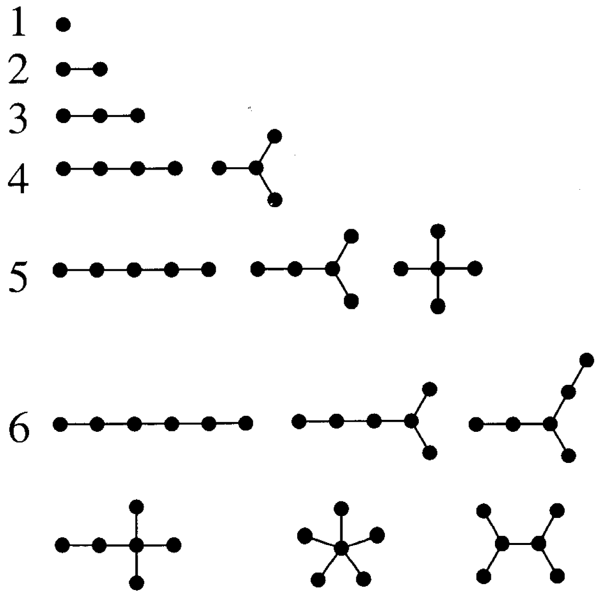
Tree



A tree is a mathematical structure which can be viewed as either a GRAPH or as a DATA STRUCTURE. The two views are equivalent, since a tree DATA STRUCTURE contains not only a set of elements, but also connections between elements, giving a tree graph.

A tree graph is a set of straight line segments connected at their ends containing no closed loops (cycles). A tree with n nodes has $n-1$ EDGES. The points of connection are known as FORKS and the segments as BRANCHES. Final segments and the nodes at their ends are called LEAVES. A tree with two BRANCHES at each FORK and with one or two LEAVES at the end of each branch is called a BINARY TREE.

When a special node is designated to turn a tree into a ROOTED TREE, it is called the ROOT (or sometimes "EVE.") In such a tree, each of the nodes which is one EDGE further away from a given EDGE is called a CHILD, and nodes connected to the same node are then called SIBLINGS.

Note that two BRANCHES placed end-to-end are equivalent to a single BRANCH which means, for example, that there is only *one* tree of order 3. The number $t(n)$ of nonisomorphic trees of order $n = 1, 2, \ldots$ (where trees of orders 1, 2, ..., 6 are illustrated above), are 1, 1, 1, 2, 3, 6, 11, 23, 47, 106, 235, ... (Sloane's A000055).

Otter showed that

$$\lim_{n\to\infty} \frac{t(n)n^{5/2}}{\alpha^n} = \beta, \qquad (1)$$

(Otter 1948, Harary and Palmer 1973, Knuth 1969), where the constants α and β are sometimes called OTTER'S TREE ENUMERATION CONSTANTS. Write the GENERATING FUNCTION for ROOTED TREES as

$$f(z) = \sum_{i=0}^{\infty} f_i z^i, \qquad (2)$$

where the COEFFICIENTS are

$$f_{i+1} = \frac{1}{i}\sum_{j=1}^{i}\left(\sum_{d|j} d f_d\right) f_{i-j+1}, \qquad (3)$$

with $f_0 = 0$ and $f_1 = 1$. Then

$$\alpha = 2.955765\ldots \qquad (4)$$

is the unique POSITIVE ROOT of

$$f\left(\frac{1}{x}\right) = 1, \qquad (5)$$

and

$$\beta = \frac{1}{\sqrt{2\pi}}\left[1 + \sum_{k=2}^{\infty} f'\left(\frac{1}{\alpha_k}\right)\frac{1}{\alpha_k}\right]^{3/2} = 0.5349485\ldots. \qquad (6)$$

see also B-TREE, BINARY TREE, CATERPILLAR GRAPH, CAYLEY TREE, CHILD, DIJKSTRA TREE, EVE, FOREST, KRUSKAL'S ALGORITHM, KRUSKAL'S TREE THEOREM, LEAF (TREE), ORCHARD-PLANTING PROBLEM, ORDERED TREE, PATH GRAPH, PLANTED PLANAR TREE, PÓLYA ENUMERATION THEOREM, QUADTREE, RED-BLACK TREE, ROOT (TREE), ROOTED TREE, SIBLING, STAR GRAPH, STERN-BROCOT TREE, WEAKLY BINARY TREE, WEIGHTED TREE

Tree-Planting Problem

see ORCHARD-PLANTING PROBLEM

Tree Searching

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

In database structures, two quantities are generally of interest: the average number of comparisons required to

1. Find an existing random record, and
2. Insert a new random record into a data structure.

Some constants which arise in the theory of digital tree searching are

$$\alpha \equiv \sum_{k=1}^{\infty} \frac{1}{2^k - 1} = 1.6066951524\ldots \qquad (1)$$

$$\beta \equiv \sum_{n=1}^{\infty} \frac{1}{(2^n - 1)^2} = 1.1373387363\ldots. \qquad (2)$$

Erdős (1948) proved that α is IRRATIONAL. The expected number of comparisons for a successful search is

$$\begin{aligned} E &= \frac{\ln n}{\ln 2} + \frac{\gamma - 1}{\ln 2} - \alpha + \tfrac{3}{2} + \delta(n) + \mathcal{O}(n^{-1/2}) \qquad (3)\\ &\sim \lg n - 0.716644\ldots + \delta(n), \qquad (4) \end{aligned}$$

and for an unsuccessful search is

$$\begin{aligned} E &= \frac{\ln n}{\ln 2} + \frac{\gamma}{\ln 2} - \alpha + \tfrac{1}{2} + \delta(n) + \mathcal{O}(n^{-1/2}) \qquad (5)\\ &\sim \lg n - 0.273948\ldots + \delta(n). \qquad (6) \end{aligned}$$

Here $\delta(n)$, $\epsilon(s)$, and $\rho(n)$ are small-amplitude periodic functions, and LG is the base 2 LOGARITHM. The VARIANCE for searching is

$$V \sim \frac{1}{12} + \frac{\pi^2 + 6}{6(\ln 2)^2} - \alpha - \beta + \epsilon(s) \sim 2.844383\ldots + \epsilon(s) \qquad (7)$$

and for inserting is

$$V \sim \frac{1}{12} + \frac{\pi^2}{6(\ln 2)^2} - \alpha - \beta + \epsilon(s) \sim 0.763014\ldots + \epsilon(s). \qquad (8)$$

The expected number of pairs of twin vacancies in a digital search tree is

$$\langle A_n\rangle = \left[\theta + 1 - \frac{1}{Q}\left(\frac{1}{\ln 2} + \alpha^2 - \alpha\right) + \rho(n)\right] n + \mathcal{O}(\sqrt{n}), \tag{9}$$

where

$$Q \equiv \prod_{k=1}^{\infty}\left(1 - \frac{1}{2^k}\right) = 0.2887880950\ldots \tag{10}$$

$$= \frac{1}{3} - \frac{1}{3\cdot 7} + \frac{1}{3\cdot 5\cdot 15} - \frac{1}{3\cdot 5\cdot 15\cdot 21} + \ldots \tag{11}$$

$$= \exp\left[-\sum_{n=1}^{\infty}\frac{1}{n(2^n - 1)}\right] \tag{12}$$

$$= \sqrt{\frac{2\pi}{\ln 2}}\exp\left(\frac{\ln 2}{24} - \frac{\pi^2}{6\ln 2}\right) \times \prod_{n=1}^{\infty}\left[1 - \exp\left(-\frac{4\pi^2 n}{\ln 2}\right)\right] \tag{13}$$

and

$$\theta = \sum_{k=1}^{\infty}\frac{k2^{k+1}}{1\cdot 3\cdot 7\cdot 16\cdots(2^k - 1)}\sum_{j=1}^{k}\frac{1}{2^j - 1} = 7.7431319855\ldots. \tag{14}$$

(Flajolet and Sedgewick 1986). The linear COEFFICIENT of $\langle A_n\rangle$ fluctuates around

$$c = \theta + 1 - \frac{1}{Q}\left(\frac{1}{\ln 2} + \alpha^2 - \alpha\right) = 0.3720486812\ldots, \tag{15}$$

which can also be written

$$c = \frac{1}{\ln 2}\int_0^{\infty}\frac{x}{1+x} \times \frac{dx}{(1+x)(1+\frac{1}{2}x)(1+\frac{1}{4}x)(1+\frac{1}{8}x)\cdots}. \tag{16}$$

(Flajolet and Richmond 1992).

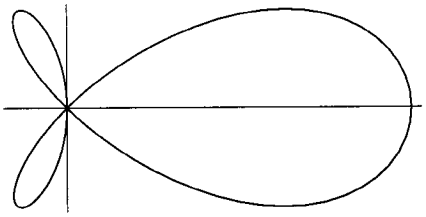
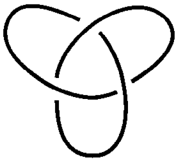
Trefoil Curve



The plane curve given by the equation

$$x^4 + x^2y^2 + y^4 = x(x^2 - y^2).$$

Trefoil Knot



The knot 03_{001}, also called the THREEFOIL KNOT, which is the unique PRIME KNOT of three crossings. It has BRAID WORD ${\sigma_1}^3$. The trefoil and its MIRROR IMAGE are not equivalent. The trefoil has ALEXANDER POLYNOMIAL $-x^2 + x - 1$ and is a (3, 2)-TORUS KNOT. The BRACKET POLYNOMIAL can be computed as follows.

$$\begin{aligned}\langle L\rangle &= A^3d^{2-1} + A^2Bd^{1-1} + A^2Bd^{1-1} + AB^2d^{2-1} \\ &\quad + A^2Bd^{1-1} + AB^2d^{2-1} + AB^2d^{2-1} + B^3d^{3-1} \\ &= A^3d^1 + 3A^2Bd^0 + 3AB^2d^1 + B^3d^2.\end{aligned}$$

Plugging in

$$\begin{aligned}B &= A^{-1} \\ d &= -A^2 - A^{-2}\end{aligned}$$

gives

$$\langle L\rangle = A^{-7} - A^{-3} - A^5.$$

The normalized one-variable KAUFFMAN POLYNOMIAL X is then given by

$$\begin{aligned}X_L &= (-A^3)^{-w(L)}\langle L\rangle = (-A^3)^{-3}(A^{-7} - A^{-3} - A^5) \\ &= A^{-4} + A^{-12} - A^{-16},\end{aligned}$$

where the WRITHE $w(L) = 3$. The JONES POLYNOMIAL is therefore

$$V(t) = L(A = t^{-1/4}) = t + t^3 - t^4 = t(1 + t^2 - t^3).$$

Since $V(t^{-1}) \neq V(t)$, we have shown that the mirror images are not equivalent.

Trial

In statistics, a trial is a single measurable random event, such as the flipping of a COIN, the generation of a RANDOM NUMBER, the dropping of a ball down the apex of a triangular lattice and having it fall into a single bin at the bottom, etc.

see also BERNOULLI TRIAL, LEXIS TRIALS, POISSON TRIALS

Trial Division

A brute-force method of finding a DIVISOR of an INTEGER n by simply plugging in one or a set of INTEGERS and seeing if they DIVIDE n. Repeated application of trial division to obtain the complete PRIME FACTORIZATION of a number is called DIRECT SEARCH FACTORIZATION. An individual integer being tested is called a TRIAL DIVISOR.

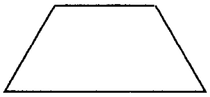
see also DIRECT SEARCH FACTORIZATION, DIVISION, PRIME FACTORIZATION

Trial Divisor

An INTEGER n which is tested to see if it divides a given number.

see also TRIAL DIVISION

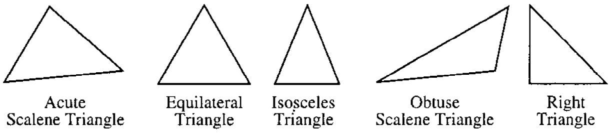
Triamond



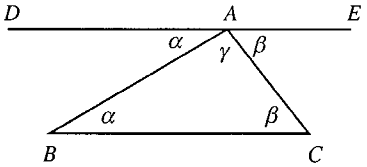
The unique 3-POLYIAMOND, illustrated above.

see also POLYIAMOND, TRAPEZOID

Triangle



A triangle is a 3-sided POLYGON sometimes (but not very commonly) called the TRIGON. All triangles are convex. An ACUTE TRIANGLE is a triangle whose three angles are all ACUTE. A triangle with all sides equal is called EQUILATERAL. A triangle with two sides equal is called ISOSCELES. A triangle having an OBTUSE ANGLE is called an OBTUSE TRIANGLE. A triangle with a RIGHT ANGLE is called RIGHT. A triangle with all sides a different length is called SCALENE.



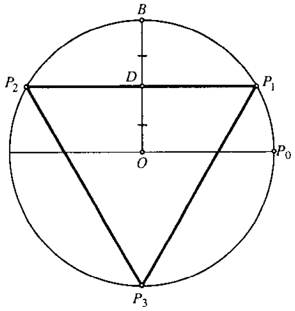
The sum of ANGLES in a triangle is 180°. This can be established as follows. Let $DAE||BC$ (DAE be PARALLEL to BC) in the above diagram, then the angles α and β

satisfy $\alpha = \angle DAB = \angle ABC$ and $\beta = \angle EAC = \angle BCE$, as indicated. Adding γ, it follows that

$$\alpha + \beta + \gamma = 180^\circ, \tag{1}$$

since the sum of angles for the line segment must equal two RIGHT ANGLES. Therefore, the sum of angles in the triangle is also 180°.

Let S stand for a triangle side and A for an angle, and let a set of Ss and As be concatenated such that adjacent letters correspond to adjacent sides and angles in a triangle. Triangles are uniquely determined by specifying three sides (SSS THEOREM), two angles and a side (AAS THEOREM), or two sides with an adjacent angle (SAS THEOREM). In each of these cases, the unknown three quantities (there are three sides and three angles total) can be uniquely determined. Other combinations of sides and angles do not uniquely determine a triangle: three angles specify a triangle only modulo a scale size (AAA THEOREM), and one angle and two sides not containing it may specify one, two, or no triangles (ASS THEOREM).



Equilateral Triangle

The RULER and COMPASS construction of the triangle can be accomplished as follows. In the above figure, take OP_0 as a RADIUS and draw $OB \perp OP_0$. Then bisect OB and construct $P_2P_1 \| OP_0$. Extending BO to locate P_3 then gives the EQUILATERAL TRIANGLE $\Delta P_1P_2P_3$.

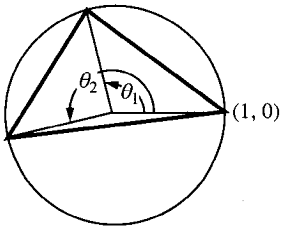
In Proposition IV.4 of the *Elements*, Euclid showed how to inscribe a CIRCLE (the INCIRCLE) in a given triangle by locating the CENTER as the point of intersection of ANGLE BISECTORS. In Proposition IV.5, he showed how to circumscribe a CIRCLE (the CIRCUMCIRCLE) about a given triangle by locating the CENTER as the point of intersection of the perpendicular bisectors.

If the coordinates of the triangle VERTICES are given by (x_i, y_i) where $i = 1, 2, 3$, then the AREA Δ is given by the DETERMINANT

$$\Delta = \frac{1}{2!}\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}. \tag{2}$$

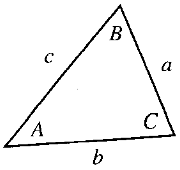
If the coordinates of the triangle VERTICES are given in 3-D by (x_i, y_i, z_i) where $i = 1, 2, 3$, then

$$\Delta = \frac{1}{2}\sqrt{\begin{vmatrix} y_1 & z_1 & 1 \\ y_2 & z_2 & 1 \\ y_3 & z_3 & 1 \end{vmatrix}^2 + \begin{vmatrix} z_1 & x_1 & 1 \\ z_2 & x_2 & 1 \\ z_3 & x_3 & 1 \end{vmatrix}^2 + \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}^2}. \tag{3}$$



In the above figure, let the CIRCUMCIRCLE passing through a triangle's VERTICES have RADIUS r, and denote the CENTRAL ANGLES from the first point to the second θ_1, and to the third point by θ_2. Then the AREA of the triangle is given by

$$\Delta = 2r^2 \left|\sin(\tfrac{1}{2}\theta_1)\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_1 - \theta_2)]\right|. \tag{4}$$



If a triangle has sides a, b, c, call the angles opposite these sides A, B, and C, respectively. Also define the SEMIPERIMETER s as HALF the PERIMETER:

$$s \equiv \tfrac{1}{2}p = \tfrac{1}{2}(a + b + c). \tag{5}$$

The AREA of a triangle is then given by HERON'S FORMULA

$$\Delta = \sqrt{s(s-a)(s-b)(s-c)}, \tag{6}$$

as well by the FORMULAS

$$\Delta = \tfrac{1}{4}\sqrt{(a+b+c)(b+c-a)(c+a-b)(a+b-c)} \tag{7}$$

$$= \tfrac{1}{4}\sqrt{2(a^2b^2 + a^2c^2 + b^2c^2) - (a^4 + b^4 + c^4)} \tag{8}$$

$$= \tfrac{1}{4}\sqrt{[(a+b)^2 - c^2][c^2 - (a-b)^2]} \tag{9}$$

$$= \tfrac{1}{4}\sqrt{p(p-2a)(p-2b)(p-2c)}, \tag{10}$$

$$= 2R^2 \sin A \sin B \sin C \tag{11}$$

$$= \frac{abc}{4R} = rs \tag{12}$$

$$= \tfrac{1}{2}ah_a \tag{13}$$

$$= \tfrac{1}{2}bc\sin A. \tag{14}$$

In the above formulas, h_i is the Altitude on side i, R is the Circumradius, and r is the Inradius (Johnson 1929, p. 11). Expressing the side lengths a, b, and c in terms of the radii a', b', and c' of the mutually tangent circles centered on the Triangle vertices (which define the Soddy Circles),

$$a = b' + c' \tag{15}$$

$$b = a' + c' \tag{16}$$

$$c = a' + b', \tag{17}$$

gives the particularly pretty form

$$\Delta = \sqrt{a'b'c'(a' + b' + c')}. \tag{18}$$

For additional Formulas, see Beyer (1987) and Baker (1884), who gives 110 Formulas for the Area of a triangle.

The Angles of a triangle satisfy

$$\cot A = \frac{b^2 + c^2 - a^2}{4\Delta} \tag{19}$$

where Δ is the Area (Johnson 1929, p. 11, with missing squared symbol added). This gives the pretty identity

$$\cot A + \cot B + \cot C = \frac{a^2 + b^2 + c^2}{4\Delta}. \tag{20}$$

Let a triangle have Angles A, B, and C. Then

$$\sin A \sin B \sin C \leq kABC, \tag{21}$$

where

$$k = \left(\frac{3\sqrt{3}}{2\pi}\right)^3 \tag{22}$$

(Abi-Khuzam 1974, Le Lionnais 1983). This can be used to prove that

$$8\omega^3 < ABC, \tag{23}$$

where ω is the Brocard Angle.

Trigonometric Functions of half angles can be expressed in terms of the triangle sides:

$$\cos(\tfrac{1}{2}A) = \sqrt{\frac{s(s-a)}{bc}} \tag{24}$$

$$\sin(\tfrac{1}{2}A) = \sqrt{\frac{(s-b)(s-c)}{bc}} \tag{25}$$

$$\tan(\tfrac{1}{2}A) = \sqrt{\frac{(s-b)(s-c)}{s(s-a)}}, \tag{26}$$

where s is the Semiperimeter.

The number of different triangles which have Integral sides and Perimeter n is

$$\begin{aligned} T(n) &= P_3(n) - \sum_{1 \leq j \leq \lfloor n/2 \rfloor} P_2(j) \\ &= \left[\frac{n^2}{12}\right] - \left\lfloor \frac{n}{4} \right\rfloor \left\lfloor \frac{n+2}{4} \right\rfloor \\ &= \begin{cases} \left[\frac{n^2}{48}\right] & \text{for } n \text{ even} \\ \left[\frac{(n+3)^2}{48}\right] & \text{for } n \text{ odd,} \end{cases} \end{aligned} \tag{27}$$

where P_2 and P_3 are Partition Functions P, $[x]$ is the Nint function, and $\lfloor x \rfloor$ is the Floor Function (Jordan *et al.* 1979, Andrews 1979, Honsberger 1985). The values of $T(n)$ for $n = 1, 2, \ldots$ are 0, 0, 1, 0, 1, 1, 2, 1, 3, 2, 4, 3, 5, 4, 7, 5, 8, 7, 10, 8, 12, 10, 14, 12, 16, ... (Sloane's A005044), which is also Alcuin's Sequence padded with two initial 0s. $T(n)$ also satisfies

$$T(2n) = T(2n-3) = P_3(n). \tag{28}$$

It is not known if a triangle with Integer sides, Medians, and Area exists (although there are incorrect Proofs of the impossibility in the literature). However, R. L. Rathbun, A. Kemnitz, and R. H. Buchholz have shown that there are infinitely many triangles with Rational sides (Heronian Triangles) with *two* Rational Medians (Guy 1994).

In the following paragraph, assume the specified sides and angles are adjacent to each other. Specifying three Angles does not uniquely define a triangle, but any two triangles with the same Angles are similar (the AAA Theorem). Specifying two Angles A and B and a side a uniquely determines a triangle with Area

$$\Delta = \frac{a^2 \sin B \sin C}{2 \sin A} = \frac{a^2 \sin B \sin(\pi - A - B)}{2 \sin A} \tag{29}$$

(the AAS Theorem). Specifying an Angle A, a side c, and an Angle B uniquely specifies a triangle with Area

$$\Delta = \frac{c^2}{2(\cot A + \cot B)} \tag{30}$$

(the ASA Theorem). Given a triangle with two sides, a the smaller and c the larger, and one known Angle A, Acute and opposite a, if $\sin A < a/c$, there are two possible triangles. If $\sin A = a/c$, there is one possible triangle. If $\sin A > a/c$, there are no possible triangles. This is the ASS Theorem. Let a be the base length and h be the height. Then

$$\Delta = \tfrac{1}{2}ah = \tfrac{1}{2}ac \sin B \tag{31}$$

(the SAS Theorem). Finally, if all three sides are specified, a unique triangle is determined with Area given by Heron's Formula or by

$$\Delta = \frac{abc}{4R}, \tag{32}$$

where R is the Circumradius. This is the SSS Theorem.

There are four Circles which are tangent to the sides of a triangle, one internal and the rest external. Their centers are the points of intersection of the Angle Bisectors of the triangle.

Any triangle can be positioned such that its shadow under an orthogonal projection is Equilateral.

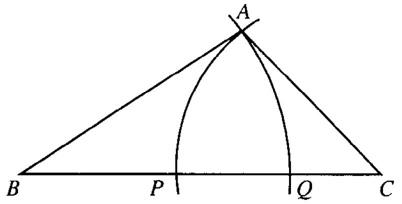
Triangle Arcs



In the above figure, the curves are arcs of a CIRCLE and

$$a = BC \tag{1}$$
$$b = CA = CP \tag{2}$$
$$c = BA = BQ. \tag{3}$$

Then

$$PQ^2 = 2BP \cdot QC. \tag{4}$$

The figure also yields the algebraic identity

$$(b + c - \sqrt{b^2 + c^2}\,)^2 = 2(\sqrt{b^2 + c^2} - b)(\sqrt{b^2 + c^2} - c). \tag{5}$$

Triangle Center

A triangle center is a point whose TRILINEAR COORDINATES are defined in terms of the side lengths and angles of a TRIANGLE. The function giving the coordinates $\alpha : \beta : \gamma$ is called the TRIANGLE CENTER FUNCTION. The four ancient centers are the CENTROID, INCENTER, CIRCUMCENTER, and ORTHOCENTER. For a listing of these and other triangle centers, see Kimberling (1994).

A triangle center is said to be REGULAR IFF there is a TRIANGLE CENTER FUNCTION which is a POLYNOMIAL in Δ, a, b, and c (where Δ is the AREA of the TRIANGLE) such that the TRILINEAR COORDINATES of the center are

$$f(a, b, c) : f(b, c, a) : f(c, a, b).$$

A triangle center is said to be a MAJOR TRIANGLE CENTER if the TRIANGLE CENTER FUNCTION α is a function of ANGLE A alone, and therefore β and γ of B and C alone, respectively.

see also MAJOR TRIANGLE CENTER, REGULAR TRIANGLE CENTER, TRIANGLE, TRIANGLE CENTER FUNCTION, TRILINEAR COORDINATES, TRILINEAR POLAR

Triangle Center Function

A HOMOGENEOUS FUNCTION $f(a, b, c)$, i.e., a function f such that

$$f(ta, tb, tc) = t^n f(a, b, c),$$

which gives the TRILINEAR COORDINATES of a TRIANGLE CENTER as

$$\alpha : \beta : \gamma = f(a, b, c) : f(b, c, a) : f(c, a, b).$$

The variables may correspond to angles (A, B, C) or side lengths (a, b, c), since these can be interconverted using the LAW OF COSINES.

see also MAJOR TRIANGLE CENTER, REGULAR TRIANGLE CENTER, TRIANGLE CENTER, TRILINEAR COORDINATES

Triangle Coefficient

A function of three variables written $\Delta(abc) \equiv \Delta(a, b, c)$ and defined by

$$\Delta(abc) \equiv \sqrt{\frac{(a + b - c)!(a - b + c)!(-a + b + c)!}{(a + b + c + 1)!}}.$$

References

Shore, B. W. and Menzel, D. H. *Principles of Atomic Spectra.* New York: Wiley, p. 273, 1968.

Triangle Condition

The condition that j takes on the values

$$j = j_1 + j_2, j_1 + j_2 - 1, \ldots, |j_1 - j_2|,$$

denoted $\Delta(j_1 j_2 j)$.

References

Sobelman, I. I. *Atomic Spectra and Radiative Transitions, 2nd ed.* Berlin: Springer-Verlag, p. 60, 1992.

Triangle Counting

Given rods of length 1, 2, ..., n, how many distinct triangles $T(n)$ can be made? Lengths for which

$$l_i = l_j + l_k$$

obviously do not give triangles, but all other combinations of three rods do. The answer is

$$T(n) = \begin{cases} \frac{1}{24}n(n-2)(2n-5) & \text{for } n \text{ even} \\ \frac{1}{24}(n-1)(n-3)(2n-1) & \text{for } n \text{ odd.} \end{cases}$$

The values for $n = 1, 2, \ldots$ are 0, 0, 0, 1, 3, 7, 13, 22, 34, 50, ... (Sloane's A002623). Somewhat surprisingly, this sequence is also given by the GENERATING FUNCTION

$$f(x) = \frac{x^4}{(1-x)^3(1-x^2)} = x^4 + 3x^5 + 7x^6 + 13x^7 + \ldots.$$

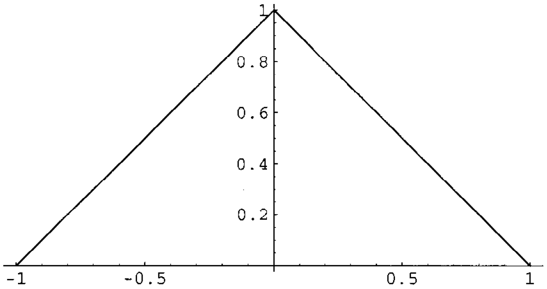
Triangle of Figurate Numbers

see FIGURATE NUMBER TRIANGLE

Triangle Function



$$\begin{aligned} \Lambda(x) &\equiv \begin{cases} 0 & |x| > 1 \\ 1 - |x| & |x| < 1 \end{cases} & (1) \\ &= \Pi(x) * \Pi(x) & (2) \\ &= \Pi(x) * H(x + \tfrac{1}{2}) - \Pi(x) * H(x - \tfrac{1}{2}), & (3) \end{aligned}$$

where Π is the RECTANGLE FUNCTION and H is the HEAVISIDE STEP FUNCTION. An obvious generalization used as an APODIZATION FUNCTION goes by the name of the BARTLETT FUNCTION.

There is also a three-argument function known as the triangle function:

$$\lambda(x, y, z) \equiv x^2 + y^2 + z^2 - 2xy - 2xz - 2yz. \quad (4)$$

It follows that

$$\lambda(a^2, b^2, c^2) = (a+b+c)(a+b-c)(a-b+c)(a-b-c). \quad (5)$$

see also ABSOLUTE VALUE, BARTLETT FUNCTION, HEAVISIDE STEP FUNCTION, RAMP FUNCTION, SGN, TRIANGLE COEFFICIENT

Triangle Inequality

Let $\mathbf{x}$ and $\mathbf{y}$ be vectors

$$|\mathbf{x}| - |\mathbf{y}| \leq |\mathbf{x} + \mathbf{y}| \leq |\mathbf{x}| + |\mathbf{y}|. \quad (1)$$

Equivalently, for COMPLEX NUMBERS z_1 and z_2,

$$|z_1| - |z_2| \leq |z_1 + z_2| \leq |z_1| + |z_2|. \quad (2)$$

A generalization is

$$\left| \sum_{k=1}^{n} a_k \right| \leq \sum_{k=1}^{n} |a_k|. \quad (3)$$

see also p-ADIC NUMBER, STRONG TRIANGLE INEQUALITY

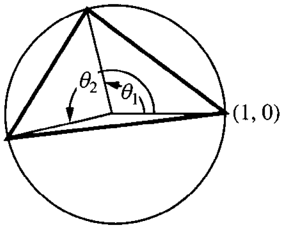
Triangle Inscribing in a Circle



Select three points at random on a unit CIRCLE. Find the distribution of possible areas. The first point can be assigned coordinates (1, 0) without loss of generality. Call the central angles from the first point to the second and third θ_1 and θ_2. The range of θ_1 can be restricted to $[0, \pi]$ because of symmetry, but θ_2 can range from $[0, 2\pi)$. Then

$$A(\theta_1, \theta_2) = 2\left|\sin(\tfrac{1}{2}\theta_1)\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_1 - \theta_2)]\right|, \quad (1)$$

so

$$\bar{A} = \frac{\int_0^\pi \int_0^{2\pi} A(\theta_1, \theta_2)\, d\theta_2\, d\theta_1}{C}, \quad (2)$$

where

$$C \equiv \int_0^\pi \int_0^{2\pi} d\theta_2\, d\theta_1 = 2\pi^2. \quad (3)$$

Therefore,

$$\begin{aligned}
\bar{A} &= \frac{2}{2\pi^2}\int_0^{\pi}\int_0^{2\pi}\left|\sin(\tfrac{1}{2}\theta_1)\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_1-\theta_2)]\right|\,d\theta_2\,d\theta_1\\
&= \frac{1}{\pi^2}\int_0^{\pi}\sin(\tfrac{1}{2}\theta_1)\left[\int_0^{2\pi}\sin(\tfrac{1}{2}\theta_2)\left|\sin[\tfrac{1}{2}(\theta_2-\theta_1)]\right|\,d\theta_2\right]d\theta_1\\
&= \frac{1}{\pi^2}\underset{\theta_2-\theta_1>0}{\int_0^{\pi}\int_0^{2\pi}}\sin(\tfrac{1}{2}\theta_1)\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_1-\theta_2)]\,d\theta_2\,d\theta_1\\
&\quad+\frac{1}{\pi^2}\underset{\theta_2-\theta_1<0}{\int_0^{\pi}\int_0^{2\pi}}\sin(\tfrac{1}{2}\theta_1)\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_1-\theta_2)]\,d\theta_2\,d\theta_1\\
&= \frac{1}{\pi^2}\int_0^{\pi}\sin(\tfrac{1}{2}\theta_1)\left[\int_{\theta_1}^{2\pi}\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_2-\theta_1)]\,d\theta_2\right]d\theta_1\\
&\quad+\frac{1}{\pi^2}\int_0^{\pi}\sin(\tfrac{1}{2}\theta_1)\left[\int_0^{\theta_1}\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_2-\theta_1)]\,d\theta_2\right]d\theta_1.
\end{aligned}\tag{4}$$

But

$$\begin{aligned}
&\int(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_2-\theta_1)]\,d\theta_2\\
&= \int\sin(\tfrac{1}{2}\theta_2)\left[\sin(\tfrac{1}{2}\theta_2)\cos(\tfrac{1}{2}\theta_2)-\sin(\tfrac{1}{2}\theta_1)\cos(\tfrac{1}{2}\theta_2)\right]\,d\theta_2\\
&= \cos(\tfrac{1}{2}\theta_1)\int\sin^2(\tfrac{1}{2}\theta_2)\,d\theta_2-\sin(\tfrac{1}{2}\theta_1)\int\sin(\tfrac{1}{2}\theta_1)\cos(\tfrac{1}{2}\theta_2)\,d\theta_2\\
&= \tfrac{1}{2}\cos(\tfrac{1}{2}\theta_1)\int(1-\cos\theta_2)\,d\theta_2-\tfrac{1}{2}\sin(\tfrac{1}{2}\theta_2)\int\sin\theta_2\,d\theta_2\\
&= \tfrac{1}{2}\cos(\tfrac{1}{2}\theta_1)(\theta_2-\sin\theta_2)+\tfrac{1}{2}\sin(\tfrac{1}{2}\theta_1)\cos(\theta_2).
\end{aligned}\tag{5}$$

Write (4) as

$$\bar{A}=\frac{1}{\pi^2}\left[\int_0^{\pi}\sin(\tfrac{1}{2}\theta_1)I_1\,d\theta_1+\int_0^{\pi}\sin(\tfrac{1}{2}\theta_1)I_2\,d\theta_1\right],\tag{6}$$

then

$$I_1\equiv\int_{\theta_1}^{2\pi}\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_2-\theta_1)]\,d\theta_2,\tag{7}$$

and

$$I_2\equiv\int_0^{\theta_1}\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_1-\theta_2)]\,d\theta_2.\tag{8}$$

From (6),

$$\begin{aligned}
I_1 &= \tfrac{1}{2}\cos(\tfrac{1}{2}\theta_2)[\theta_2-\sin\theta_2]_{\theta_1}^{2\pi}+\tfrac{1}{2}\sin(\tfrac{1}{2}\theta_1)[\cos\theta_2]_{\theta_1}^{2\pi}\\
&= \tfrac{1}{2}\cos(\tfrac{1}{2}\theta_1)(2\pi-\theta_1+\sin\theta_1)\\
&\quad+\tfrac{1}{2}\sin(\tfrac{1}{2}\theta_1)(1-\cos\theta_1)\\
&= \pi\cos(\tfrac{1}{2}\theta_1)-\tfrac{1}{2}\theta_1\cos(\tfrac{1}{2}\theta_1)+\tfrac{1}{2}[\cos(\tfrac{1}{2}\theta_1)\sin\theta_1\\
&\quad-\cos\theta_1\sin(\tfrac{1}{2}\theta_1)]+\tfrac{1}{2}\sin(\tfrac{1}{2}\theta_1)\\
&= \pi\cos(\tfrac{1}{2}\theta_1)-\tfrac{1}{2}\theta_1\cos(\tfrac{1}{2}\theta_1)+\tfrac{1}{2}+\tfrac{1}{2}\sin(\theta_1-\tfrac{1}{2}\theta_1)\\
&\quad+\tfrac{1}{2}\sin(\tfrac{1}{2}\theta_1)\\
&= \pi\cos(\tfrac{1}{2}\theta_1)-\tfrac{1}{2}\theta_1\cos(\tfrac{1}{2}\theta_1)+\sin(\tfrac{1}{2}\theta_1),
\end{aligned}\tag{9}$$

so

$$\int_0^{\pi}I_1\sin(\tfrac{1}{2}\theta_1)\,d\theta_1=\tfrac{5}{4}\pi.\tag{10}$$

Also,

$$\begin{aligned}
I_2 &= \tfrac{1}{2}\cos(\tfrac{1}{2}\theta_1)[\sin\theta_2-\theta_2]_0^{\theta_1}-\tfrac{1}{2}\sin(\tfrac{1}{2}\theta_1)[\cos\theta_2]_0^{\theta_1}\\
&= \tfrac{1}{2}\cos(\tfrac{1}{2}\theta_2)(\sin\theta_1-\theta_1)-\tfrac{1}{2}\sin(\tfrac{1}{2}\theta_1)(\cos\theta_1-1)\\
&= -\tfrac{1}{2}\theta_1\cos(\tfrac{1}{2}\theta_1)\\
&\quad+\tfrac{1}{2}[\sin\theta_1\cos(\tfrac{1}{2}\theta_1)-\cos\theta_1\sin(\tfrac{1}{2}\theta_2)]\\
&\quad+\tfrac{1}{2}\sin(\tfrac{1}{2}\theta_1)\\
&= -\tfrac{1}{2}\theta_1\cos(\tfrac{1}{2}\theta_1)+\sin(\tfrac{1}{2}\theta_1),
\end{aligned}\tag{11}$$

so

$$\int_0^{\pi}I_2\sin(\tfrac{1}{2}\theta_1)\,d\theta_1=\tfrac{1}{4}\pi.\tag{12}$$

Combining (10) and (12) gives

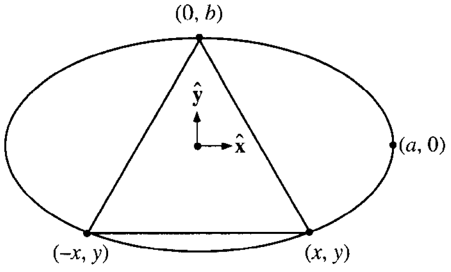
$$\bar{A}=\frac{1}{\pi^2}\left(\frac{5\pi}{4}+\frac{\pi}{4}\right)=\frac{3}{2\pi}\approx 0.4775.\tag{13}$$

The VARIANCE is

$$\begin{aligned}
{\sigma_A}^2 &= \frac{1}{2\pi^2}\int_0^{\pi}\int_0^{2\pi}[A(\theta_1,\theta_2)-\tfrac{3}{2\pi}]^2\,d\theta_2\,d\theta_1\\
&= \frac{1}{2\pi^2}\int_0^{\pi}\int_0^{2\pi}\Big[2\left|\sin(\tfrac{1}{2}\theta_1)\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_1-\theta_2)]\right|\\
&\quad-\frac{3}{2\pi}\Big]^2\,d\theta_2\,d\theta_1\\
&= \frac{1}{2\pi^2}\int_0^{\pi}\int_0^{2\pi}\Big\{4\sin^2(\tfrac{1}{2}\theta_1)\sin^2(\tfrac{1}{2}\theta_2)\sin^2[\tfrac{1}{2}(\theta_2-\theta_1)]\\
&\quad-\frac{6}{\pi}\left|\sin(\tfrac{1}{2}\theta_1)\sin(\tfrac{1}{2}\theta_2)\sin[\tfrac{1}{2}(\theta_1-\theta_2)]\right|+\frac{9}{4\pi^2}\Big\}\,d\theta_2\,d\theta_1\\
&= \frac{1}{2\pi^2}\Big[\int_0^{\pi}\pi(2+\theta_1)\sin^2(\tfrac{1}{2}\theta_1)\,d\theta_1\\
&\quad-\frac{6}{\pi}\left(\frac{5\pi}{4}+\frac{\pi}{4}\right)+\frac{9}{4\pi^2}(2\pi^2)\Big]\\
&= \frac{1}{2\pi^2}\left(\frac{3\pi^2}{4}-9+\frac{9}{2}\right)=\frac{1}{2\pi^2}\left(\frac{3\pi^2}{4}-\frac{9}{2}\right)\\
&= \frac{3(\pi^2-6)}{8\pi^2}\approx 0.1470.
\end{aligned}\tag{14}$$

see also POINT-POINT DISTANCE—1-D, TETRAHEDRON INSCRIBING

Triangle Inscribing in an Ellipse



To inscribe an EQUILATERAL TRIANGLE in an ELLIPSE, place the top VERTEX at $(0, b)$, then solve to find the (x, y) coordinate of the other two VERTICES.

$$\sqrt{x^2 + (b-y)^2} = 2x \tag{1}$$

$$x^2 + (b-y)^2 = 4x^2 \tag{2}$$

$$3x^2 = (b-y)^2. \tag{3}$$

Now plugging in the equation of the ELLIPSE

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, \tag{4}$$

gives

$$3a^2\left(1 - \frac{y^2}{b^2}\right) = b^2 - 2by + y^2 \tag{5}$$

$$y^2\left(1 + 3\frac{a^2}{b^2}\right) - 2by + (b^2 - 3a^2) = 0 \tag{6}$$

$$\begin{aligned} y &= \frac{2b - \sqrt{4b^2 - 4(b^2-3a^2)\left(1+3\frac{a^2}{b^2}\right)}}{2\left(1+3\frac{a^2}{b^2}\right)} \\ &= \frac{1 - \sqrt{1 - \left(1-3\frac{a^2}{b^2}\right)\left(1+3\frac{a^2}{b^2}\right)}}{1+3\frac{a^2}{b^2}}\,b, \end{aligned} \tag{7}$$

and

$$x = \pm a\sqrt{1 - \frac{y^2}{b^2}}. \tag{8}$$

Triangle Postulate

The sum of the ANGLES of a TRIANGLE is two RIGHT ANGLES. This POSTULATE is equivalent to the PARALLEL AXIOM.

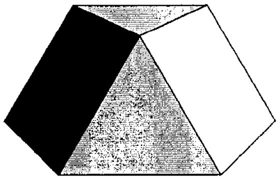
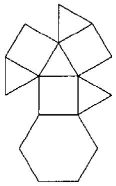
Triangular Cupola





JOHNSON SOLID J_3. The bottom six VERTICES are

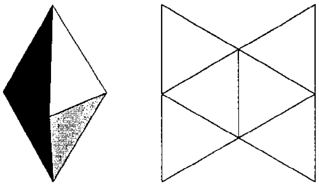
$$(\pm\tfrac{1}{2}\sqrt{3}, \pm\tfrac{1}{2}, 0), (0, \pm 1, 0),$$

and the top three VERTICES are

$$\left(\frac{1}{\sqrt{3}},0,\sqrt{\frac{2}{3}}\right),-\left(\frac{1}{2\sqrt{3}},\pm\frac{1}{2},\sqrt{\frac{2}{3}}\right).$$

see also JOHNSON SOLID

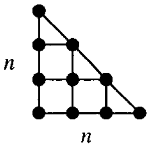
Triangular Dipyramid



The triangular (or TRIGONAL) dipyramid is one of the convex DELTAHEDRA, and JOHNSON SOLID J_{12}.

see also DELTAHEDRON, DIPYRAMID, JOHNSON SOLID, PENTAGONAL DIPYRAMID

Triangular Graph



The triangular graph with n nodes on a side is denoted $T(n)$. Tutte (1970) showed that the CHROMATIC POLYNOMIALS of planar triangular graphs possess a ROOT close to $\phi^2 = 2.618033\ldots$, where ϕ is the GOLDEN MEAN. More precisely, if n is the number of VERTICES of G, then

$$P_G(\phi^2) \leq \phi^{5-n}$$

(Le Lionnais 1983, p. 46). Every planar triangular graph possesses a VERTEX of degree 3, 4, or 5 (Le Lionnais 1983, pp. 49 and 53).

Triangular Matrix

An upper triangular MATRIX U is defined by

$$U_{ij} = \begin{cases} a_{ij} & \text{for } i \leq j \\ 0 & \text{for } i > j. \end{cases} \tag{1}$$

Written explicitly,

$$\mathsf{U} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ 0 & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & a_{nn} \end{bmatrix}. \tag{2}$$

A lower triangular MATRIX L is defined by

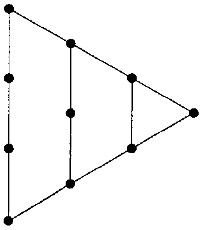
$$L_{ij} = \begin{cases} a_{ij} & \text{for } i \geq j \\ 0 & \text{for } i < j. \end{cases} \tag{3}$$

Written explicitly,

$$\mathsf{L} = \begin{bmatrix} a_{11} & 0 & \cdots & 0 \\ a_{21} & a_{22} & \cdots & 0 \\ \vdots & \vdots & \ddots & 0 \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}. \tag{4}$$

see also HESSENBERG MATRIX, HILBERT MATRIX, MATRIX, VANDERMONDE MATRIX

Triangular Number



A FIGURATE NUMBER of the form $T_n \equiv n(n+1)/2$ obtained by building up regular triangles out of dots. The first few triangle numbers are 1, 3, 6, 10, 15, 21, ... (Sloane's A000217). $T_4 = 10$ gives the number and arrangement of BOWLING pins, while $T_5 = 15$ gives the number and arrangement of balls in BILLIARDS. Triangular numbers satisfy the RECURRENCE RELATION

$${T_{n+1}}^2 - {T_n}^2 = (n+1)^3, \tag{1}$$

as well as

$$3T_n + T_{n-1} = T_{2n} \tag{2}$$

$$3T_n + T_{n+1} = T_{2n+1} \tag{3}$$

$$1+3+5+\ldots+(2n-1) = T_n + T_{n-1} \tag{4}$$

and

$$(2n+1)^2 = 8T+1 = T_{n-1} + 6T_n + T_{n+1} \tag{5}$$

(Conway and Guy 1996). They have the simple GENERATING FUNCTION

$$f(x) = \frac{x}{(1-x)^3} = x+3x^2+6x^3+10x^4+15x^5+\ldots. \tag{6}$$

Every triangular number is also a HEXAGONAL NUMBER, since

$$\tfrac{1}{2}r(r+1) = \begin{cases} \left(\frac{r+1}{2}\right)\left[2\left(\frac{r+1}{2}\right)-1\right] & \text{for } r \text{ odd} \\ \left(-\frac{r}{2}\right)\left[2\left(-\frac{r}{2}\right)-1\right] & \text{for } r \text{ even.} \end{cases} \tag{7}$$

Also, every PENTAGONAL NUMBER is 1/3 of a triangular number. The sum of consecutive triangular numbers is a SQUARE NUMBER, since

$$\begin{aligned} T_r + T_{r-1} &= \tfrac{1}{2}r(r+1) + \tfrac{1}{2}(r-1)r \\ &= \tfrac{1}{2}r[(r+1)+(r-1)] = r^2. \end{aligned} \tag{8}$$

Interesting identities involving triangular numbers and SQUARE NUMBERS are

$$\sum_{k=1}^{2n-1} (-1)^{k+1} T_k = n^2 \tag{9}$$

$$T_n{}^2 = \sum_{k=1}^{n} k^3 = \tfrac{1}{4}n^2(n+1)^2 \tag{10}$$

$$\sum_{k=1,3,\ldots,q} k^3 = T_n \tag{11}$$

for q ODD and

$$n = \tfrac{1}{2}(q^2 + 2q - 1). \tag{12}$$

All EVEN PERFECT NUMBERS are triangular T_p with PRIME p. Furthermore, every EVEN PERFECT NUMBER $P > 6$ is of the form

$$P = 1 + 9T_n = T_{3n+1}, \tag{13}$$

where T_n is a triangular number with $n = 8j + 2$ (Eaton 1995, 1996). Therefore, the nested expression

$$9(9\cdots(9(9(9(9T_n+1)+1)+1)+1)\ldots+1)+1 \tag{14}$$

generates triangular numbers for any T_n. An INTEGER k is a triangular number IFF $8k + 1$ is a SQUARE NUMBER > 1.

The numbers 1, 36, 1225, 41616, 1413721, 48024900, ... (Sloane's A001110) are SQUARE TRIANGULAR NUMBERS, i.e., numbers which are simultaneously triangular and SQUARE (Pietenpol 1962). Numbers which are simultaneously triangular and TETRAHEDRAL satisfy the BINOMIAL COEFFICIENT equation

$$\binom{n}{2} = \binom{m}{3}, \tag{15}$$

the only solutions of which are $(m, n) = (10, 16)$, (22, 56), and (36, 120) (Guy 1994, p. 147).

The smallest of two INTEGERS for which $n^3 - 13$ is four times a triangular number is 5 (Cesaro 1886; Le Lionnais 1983, p. 56). The only FIBONACCI NUMBERS which are triangular are 1, 3, 21, and 55 (Ming 1989), and the only PELL NUMBER which is triangular is 1 (McDaniel 1996). The BEAST NUMBER 666 is triangular, since

$$T_{6\cdot 6} = T_{36} = 666. \tag{16}$$

In fact, it is the largest REPDIGIT triangular number (Bellew and Weger 1975–76).

FERMAT'S POLYGONAL NUMBER THEOREM states that every POSITIVE INTEGER is a sum of *most* three TRIANGULAR NUMBERS, four SQUARE NUMBERS, five PENTAGONAL NUMBERS, and n n-POLYGONAL NUMBERS. Gauss proved the triangular case, and noted the event in his diary on July 10, 1796, with the notation

$$**\mathit{E\Upsilon RHKA} \qquad \mathit{num} = \Delta + \Delta + \Delta. \tag{17}$$

This case is equivalent to the statement that every number of the form $8m + 3$ is a sum of three ODD SQUARES (Duke 1997). Dirichlet derived the number of ways in which an INTEGER m can be expressed as the sum of three triangular numbers (Duke 1997). The result is particularly simple for a PRIME of the form $8m + 3$, in which case it is the number of squares mod $8m+3$ minus the number of nonsquares mod $8m + 3$ in the INTERVAL $4m + 1$ (Deligne 1973).

The only triangular numbers which are the PRODUCT of three consecutive INTEGERS are 6, 120, 210, 990, 185136, 258474216 (Guy 1994, p. 148).

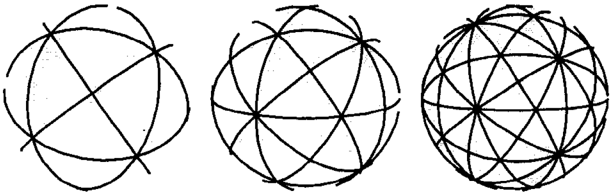
Triangular Symmetry Group



(2, 3, 3) (2, 3, 4) (2, 3, 5)

Given a TRIANGLE with angles (π/p, π/q, π/r), the resulting symmetry GROUP is called a (p, q, r) triangle group (also known as a SPHERICAL TESSELLATION). In 3-D, such GROUPS must satisfy

$$\frac{1}{p}+\frac{1}{q}+\frac{1}{r}>1,$$

and so the only solutions are $(2,2,n)$, $(2,3,3)$, $(2,3,4)$, and $(2,3,5)$ (Ball and Coxeter 1987). The group $(2,3,6)$ gives rise to the semiregular planar TESSELLATIONS of types 1, 2, 5, and 7. The group $(2,3,7)$ gives hyperbolic tessellations.

Triangulation

Triangulation is the division of a surface into a set of TRIANGLES, usually with the restriction that each TRIANGLE side is entirely shared by two adjacent TRIANGLES. It was proved in 1930 that every surface has a triangulation, but it might require an infinite number of TRIANGLES. A surface with a finite number of triangles in its triangulation is called COMPACT. B. Chazelle showed that an arbitrary SIMPLE POLYGON can be triangulated in linear time.

Tribonacci Number

The tribonacci numbers are a generalization of the FIBONACCI NUMBERS defined by $T_1 = 1$, $T_2 = 1$, $T_3 = 2$, and the RECURRENCE RELATION

$$T_n = T_{n-1} + T_{n-2} + T_{n-3} \qquad (1)$$

for $n \geq 4$. The represent the $n = 3$ case of the FIBONACCI n-STEP NUMBERS. The first few terms are 1, 1, 2, 4, 7, 13, 24, 44, 81, 149, ... (Sloane's A000073). The ratio of adjacent terms tends to 1.83929, which is the REAL ROOT of $x^4 - 2x^3 + 1 = 0$. The Tribonacci numbers can also be computed using the GENERATING FUNCTION

$$\begin{aligned}\frac{1}{1-z-z^2-z^3} &= 1 + z + 2z^2 + 4z^3 + 7z^4 \\ &\quad + 13z^5 + 24z^6 + 44z^7 + 81z^8 + 149z^9 + \ldots. \qquad (2)\end{aligned}$$

An explicit FORMULA for T_n is also given by

$$\left[3\frac{\{\frac{1}{3}(19+3\sqrt{33})^{1/3}+\frac{1}{3}(19-3\sqrt{33})^{1/3}+\frac{1}{3}\}^n(586+102\sqrt{33})^{1/3}}{(586+102\sqrt{33})^{2/3}+4-2(586+102\sqrt{33})^{1/3}}\right], \qquad (3)$$

where $[x]$ denotes the NINT function (Plouffe). The first part of a NUMERATOR is related to the REAL root of $x^3 - x^2 - x - 1$, but determination of the DENOMINATOR requires an application of the LLL ALGORITHM. The numbers increase asymptotically to

$$T_n \sim c^n, \qquad (4)$$

where

$$\begin{aligned}c &= (\tfrac{19}{27} + \tfrac{1}{9}\sqrt{33}\,)^{1/3} + \tfrac{4}{9}(\tfrac{19}{27} + \tfrac{1}{9}\sqrt{33}\,)^{-1/3} + \tfrac{1}{3} \\ &= 1.83928675521\ldots \qquad (5)\end{aligned}$$

(Plouffe).

Trichotomy Law

Every REAL NUMBER is NEGATIVE, 0, or POSITIVE.

Tricolorable

A projection of a LINK is tricolorable if each of the strands in the projection can be colored in one of three different colors such that, at each crossing, all three colors come together or only one does and at least two different colors are used. The TREFOIL KNOT and trivial 2-link are tricolorable, but the UNKNOT, WHITEHEAD LINK, and FIGURE-OF-EIGHT KNOT are not.

If the projection of a knot is tricolorable, then REIDEMEISTER MOVES on the knot preserve tricolorability, so either every projection of a knot is tricolorable or none is.

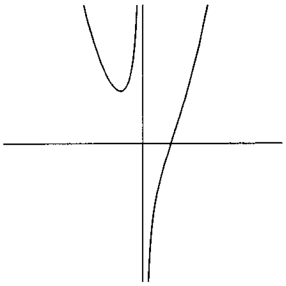
Trident

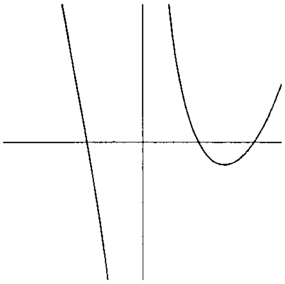


The plane curve given by the equation

$$xy = x^3 - a^3.$$

see also TRIDENT OF DESCARTES, TRIDENT OF NEWTON

Trident of Descartes



The plane curve given by the equation

$$(a+x)(a-x)(2a-x) = x^3 - 2ax^2 - a^2x + 2a^3 = axy$$

$$y = \frac{(a+x)(a-x)(2a-x)}{ax}$$

The above plot has $a = 2$.

Trident of Newton

The CUBIC CURVE defined by

$$ax^3 + bx^2 + cx + d = xy$$

with $a \neq 0$. The curve cuts the axis in either one or three points. It was the 66th curve in Newton's classification of CUBICS. Newton stated that the curve has four infinite legs and that the y-axis is an ASYMPTOTE to two tending toward contrary parts.

Tridiagonal Matrix

A MATRIX with NONZERO elements only on the diagonal and slots horizontally or vertically adjacent the diagonal. A general 4 × 4 tridiagonal MATRIX has the form

$$\begin{bmatrix} a_{11} & a_{12} & 0 & 0 \\ a_{21} & a_{22} & a_{23} & 0 \\ 0 & a_{32} & a_{33} & a_{34} \\ 0 & 0 & a_{43} & a_{44} \end{bmatrix}.$$

Inversion of such a matrix requires only n (as opposed to n^3) arithmetic operations (Acton 1990).

Trigonometric Substitution

INTEGRALS of the form

$$\int f(\cos\theta,\sin\theta)\,d\theta \tag{1}$$

can be solved by making the substitution $z=e^{i\theta}$ so that $dz=ie^{i\theta}\,d\theta$ and expressing

$$\cos\theta=\frac{e^{i\theta}+e^{-i\theta}}{2}=\frac{z+z^{-1}}{2} \tag{2}$$

$$\sin\theta=\frac{e^{i\theta}-e^{-i\theta}}{2i}=\frac{z-z^{-1}}{2i}. \tag{3}$$

The integral can then be solved by CONTOUR INTEGRATION.

Alternatively, making the substitution $t\equiv\tan(\theta/2)$ transforms (1) into

$$\int f\left(\frac{2t}{1+t^2},\frac{1-t^2}{1+t^2}\right)\frac{2\,dt}{1+t^2}. \tag{4}$$

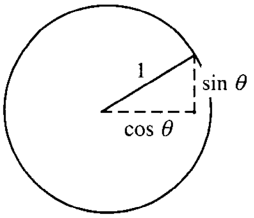
The following table gives trigonometric substitutions which can be used to transform integrals involving square roots.

Form	Substitution
$\sqrt{a^2-x^2}$	$x=a\sin\theta$
$\sqrt{a^2+x^2}$	$x=a\tan\theta$
$\sqrt{x^2-a^2}$	$x=a\sec\theta$

see also HYPERBOLIC SUBSTITUTION

Trigonometry

The study of ANGLES and of the angular relationships of planar and 3-D figures is known as trigonometry. The trigonometric functions (also called the CIRCULAR FUNCTIONS) comprising trigonometry are the COSECANT $\csc x$, COSINE $\cos x$, COTANGENT $\cot x$, SECANT $\sec x$, SINE $\sin x$, and TANGENT $\tan x$. The inverses of these functions are denoted $\csc^{-1}x$, $\cos^{-1}x$, $\cot^{-1}x$, $\sec^{-1}x$, $\sin^{-1}x$, and $\tan^{-1}x$. Note that the f^{-1} NOTATION here means INVERSE FUNCTION, *not* f to the -1 POWER.



The trigonometric functions are most simply defined using the UNIT CIRCLE. Let θ be an ANGLE measured counterclockwise from the x-AXIS along an ARC of the CIRCLE. Then $\cos\theta$ is the horizontal coordinate of the ARC endpoint, and $\sin\theta$ is the vertical component. The RATIO $\sin\theta/\cos\theta$ is defined as $\tan\theta$. As a result of this definition, the trigonometric functions are periodic with period 2π, so

$$\text{func}(2\pi n + \theta) = \text{func}(\theta), \tag{1}$$

where n is an INTEGER and func is a trigonometric function.

From the PYTHAGOREAN THEOREM,

$$\sin^2\theta + \cos^2\theta = 1. \tag{2}$$

Therefore, it is also true that

$$\tan^2\theta + 1 = \sec^2\theta \tag{3}$$

$$1 + \cot^2\theta = \csc^2\theta. \tag{4}$$

The trigonometric functions can be defined algebraically in terms of COMPLEX EXPONENTIALS (i.e., using the EULER FORMULA) as

$$\sin z \equiv \frac{e^{iz} - e^{-iz}}{2i} \tag{5}$$

$$\csc z \equiv \frac{1}{\sin z} = \frac{2i}{e^{iz} - e^{-iz}} \tag{6}$$

$$\cos z \equiv \frac{e^{iz} + e^{-iz}}{2} \tag{7}$$

$$\sec z \equiv \frac{1}{\cos z} = \frac{2}{e^{iz} + e^{-iz}} \tag{8}$$

$$\tan z \equiv \frac{\sin z}{\cos z} = \frac{e^{iz} - e^{-iz}}{i(e^{iz} + e^{-iz})} \tag{9}$$

$$\cot z \equiv \frac{1}{\tan z} = \frac{i(e^{iz} + e^{-iz})}{e^{iz} - e^{-iz}} = \frac{i(1 + e^{-2iz})}{1 - e^{-2iz}}. \tag{10}$$

OSBORNE'S RULE gives a prescription for converting trigonometric identities to analogous identities for HYPERBOLIC FUNCTIONS.

The ANGLES $n\pi/m$ (with m, n integers) for which the trigonometric function may be expressed in terms of finite root extraction of *real numbers* are limited to values of m which are precisely those which produce constructible POLYGONS. Gauss showed these to be of the form

$$m = 2^k p_1 p_2 \cdots p_s, \tag{11}$$

where k is an INTEGER ≥ 0 and the p_i are distinct FERMAT PRIMES. The first few values are m = 1, 2, 3, 4, 5, 6, 8, 10, 12, 15, 16, 17, 20, ... (Sloane's A003401). Although formulas for trigonometric functions may be found analytically for other m as well, the expressions involve ROOTS of COMPLEX NUMBERS obtained by solving a CUBIC, QUARTIC, or higher order equation. The cases $m = 7$ and $m = 9$ involve the CUBIC EQUATION and QUARTIC EQUATION, respectively. A partial table of the analytic values of SINE, COSINE, and TANGENT for arguments π/m is given below. Derivations of these formulas appear in the following entries.

°	rad	$\sin x$	$\cos x$	$\tan x$
0.0	0	0	1	0
15.0	$\frac{1}{12}\pi$	$\frac{1}{4}(\sqrt{6} - \sqrt{2})$	$\frac{1}{4}(\sqrt{6} + \sqrt{2})$	$2 - \sqrt{3}$
18.0	$\frac{1}{10}\pi$	$\frac{1}{4}(\sqrt{5} - 1)$	$\frac{1}{4}\sqrt{10 + 2\sqrt{5}}$	$\frac{1}{5}\sqrt{25 - 10\sqrt{5}}$
22.5	$\frac{1}{8}\pi$	$\frac{1}{2}\sqrt{2 - \sqrt{2}}$	$\frac{1}{2}\sqrt{2 + \sqrt{2}}$	$\sqrt{2} - 1$
30.0	$\frac{1}{6}\pi$	$\frac{1}{2}$	$\frac{1}{2}\sqrt{3}$	$\frac{1}{3}\sqrt{3}$
36.0	$\frac{1}{5}\pi$	$\frac{1}{4}\sqrt{10 - 2\sqrt{5}}$	$\frac{1}{4}(1 + \sqrt{5})$	$\sqrt{5 - 2\sqrt{5}}$
45.0	$\frac{1}{4}\pi$	$\frac{1}{2}\sqrt{2}$	$\frac{1}{2}\sqrt{2}$	1
60.0	$\frac{1}{3}\pi$	$\frac{1}{2}\sqrt{3}$	$\frac{1}{2}$	$\sqrt{3}$
90.0	$\frac{1}{2}\pi$	1	0	∞
180.0	π	0	-1	0

The INVERSE TRIGONOMETRIC FUNCTIONS are generally defined on the following domains.

Function	Domain
$\sin^{-1} x$	$-\frac{1}{2}\pi \leq y \leq \frac{1}{2}\pi$
$\cos^{-1} x$	$0 \leq y \leq \pi$
$\tan^{-1} x$	$-\frac{1}{2}\pi < y < \frac{1}{2}\pi$
$\csc^{-1} x$	$0 \leq y \leq \frac{1}{2}\pi$ or $\pi \leq y \leq \frac{3\pi}{2}$
$\sec^{-1} x$	$0 \leq y \leq \pi$
$\cot^{-1} x$	$0 \leq y \leq \frac{1}{2}\pi$ or $-\pi \leq y \leq -\frac{1}{2}\pi$

Inverse-forward identities are

$$\tan^{-1}(\cot x) = \tfrac{1}{2}\pi - x \tag{12}$$

$$\sin^{-1}(\cos x) = \tfrac{1}{2}\pi - x \tag{13}$$

$$\sec^{-1}(\csc x) = \tfrac{1}{2}\pi - x, \tag{14}$$

and forward-inverse identities are

$$\cos(\sin^{-1} x) = \sqrt{1 - x^2} \tag{15}$$

$$\cos(\tan^{-1} x) = \frac{1}{\sqrt{1 + x^2}} \tag{16}$$

$$\sin(\cos^{-1} x) = \sqrt{1 - x^2}$$

$$\sin(\tan^{-1} x) = \frac{x}{\sqrt{1 + x^2}} \tag{17}$$

$$\tan(\cos^{-1} x) = \frac{\sqrt{1 - x^2}}{x} \tag{18}$$

$$\tan(\sin^{-1} x) = \frac{x}{\sqrt{1 - x^2}}. \tag{19}$$

Inverse sum identities include

$$\sin^{-1} x + \cos^{-1} x = \tfrac{1}{2}\pi \tag{20}$$

$$\tan^{-1} x + \cot^{-1} x = \tfrac{1}{2}\pi \tag{21}$$

$$\sec^{-1} x + \csc^{-1} x = \tfrac{1}{2}\pi, \tag{22}$$

where (20) follows from

$$x = \sin(\sin^{-1} x) = \cos(\tfrac{1}{2}\pi - \sin^{-1} x). \tag{23}$$

Complex inverse identities in terms of LOGARITHMS include

$$\begin{aligned}
\sin^{-1}(z) &= -i\ln(iz \pm \sqrt{1-z^2}\,) && (24)\\
\cos^{-1}(z) &= -i\ln(z \pm i\sqrt{1-z^2}\,) && (25)\\
\tan^{-1}(z) &= -i\ln\left(\frac{1+iz}{\sqrt{1+z^2}}\right) && (26)\\
&= \tfrac{1}{2}i\ln\left(\frac{1-iz}{1+iz}\right). && (27)
\end{aligned}$$

For IMAGINARY arguments,

$$\begin{aligned}
\sin(iz) &= i\sinh z && (28)\\
\cos(iz) &= \cosh z. && (29)
\end{aligned}$$

For COMPLEX arguments,

$$\begin{aligned}
\sin(x+iy) &= \sin x\cosh y + i\cos x\sinh y && (30)\\
\cos(x+iy) &= \cos x\cosh y - i\sin x\sinh y. && (31)
\end{aligned}$$

For the ABSOLUTE SQUARE of COMPLEX arguments $z = x+iy$,

$$\begin{aligned}
|\sin(x+iy)|^2 &= \sin^2 x + \sinh^2 y && (32)\\
|\cos(x+iy)|^2 &= \cos^2 x + \sinh^2 y. && (33)
\end{aligned}$$

The MODULUS also satisfies the curious identity

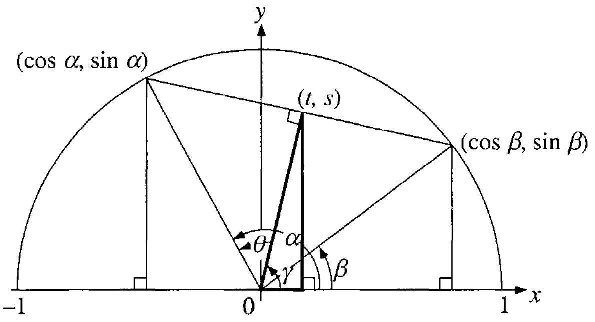
$$|\sin(x+iy)| = |\sin x + \sin(iy)|. \tag{34}$$

The only functions satisfying identities of this form,

$$|f(x+iy)| = |f(x) + f(iy)| \tag{35}$$

are $f(z) = Az$, $f(z) = A\sin(bz)$, and $f(z) = A\sinh(bz)$ (Robinson 1957).

Trigonometric product formulas can be derived using the following figure (Kung 1996).



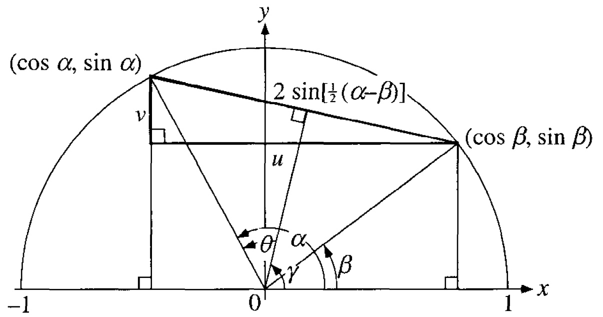
In the figure,

$$\begin{aligned}
\theta &= \tfrac{1}{2}(\alpha-\beta) && (36)\\
\gamma &= \tfrac{1}{2}(\alpha+\beta), && (37)
\end{aligned}$$

so

$$s = \tfrac{1}{2}(\sin\alpha + \sin\beta) = \cos[\tfrac{1}{2}(\alpha-\beta)]\sin[\tfrac{1}{2}(\alpha+\beta)] \tag{38}$$

$$t = \tfrac{1}{2}(\cos\alpha + \cos\beta) = \cos[\tfrac{1}{2}(\alpha-\beta)]\cos[\tfrac{1}{2}(\alpha+\beta)]. \tag{39}$$



With θ and γ as previously defined, the above figure (Kung 1996) gives

$$u = \cos\beta - \cos\alpha = 2\sin[\tfrac{1}{2}(\alpha-\beta)]\sin[\tfrac{1}{2}(\alpha+\beta)] \tag{40}$$

$$v = \sin\alpha - \sin\beta = 2\sin[\tfrac{1}{2}(\alpha-\beta)]\cos[\tfrac{1}{2}(\alpha+\beta)]. \tag{41}$$

Angle addition FORMULAS express trigonometric functions of sums of angles $\alpha \pm \beta$ in terms of functions of α and β. They can be simply derived used COMPLEX exponentials and the EULER FORMULA,

$$\begin{aligned}
\sin(\alpha+\beta) &= \frac{e^{i(\alpha+\beta)} - e^{-i(\alpha+\beta)}}{2i} = \frac{e^{i\alpha}e^{i\beta} - e^{-i\alpha}e^{-i\beta}}{2i}\\
&= \frac{(\cos\alpha + i\sin\alpha)(\cos\beta + i\sin\beta)}{2i}\\
&\quad - \frac{(\cos\alpha - i\sin\alpha)(\cos\beta - i\sin\beta)}{2i}\\
&= \frac{\cos\alpha\cos\beta + i\sin\beta\cos\alpha + i\sin\alpha\cos\beta - \sin\alpha\sin\beta}{2i}\\
&\quad + \frac{-\cos\alpha\cos\beta + i\cos\alpha\sin\beta + i\sin\alpha\cos\beta + \sin\alpha\sin\beta}{2i}\\
&= \sin\alpha\cos\beta + \sin\beta\cos\alpha
\end{aligned} \tag{42}$$

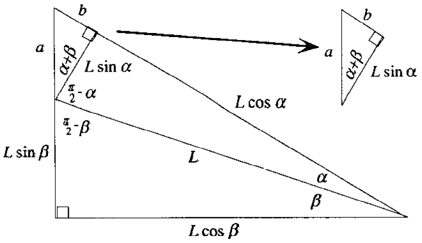
$$\begin{aligned}
\cos(\alpha+\beta) &= \frac{e^{i(\alpha+\beta)} + e^{-i(\alpha+\beta)}}{2} = \frac{e^{i\alpha}e^{i\beta} + e^{-i\alpha}e^{-i\beta}}{2}\\
&= \frac{(\cos\alpha + i\sin\alpha)(\cos\beta + i\sin\beta)}{2}\\
&\quad + \frac{(\cos\alpha - i\sin\alpha)(\cos\beta - i\sin\beta)}{2}\\
&= \frac{\cos\alpha\cos\beta + i\cos\alpha\sin\beta + i\sin\alpha\cos\beta - \sin\alpha\sin\beta}{2}\\
&\quad + \frac{\cos\alpha\cos\beta - i\cos\alpha\sin\beta - i\sin\alpha\cos\beta - \sin\alpha\sin\beta}{2}\\
&= \cos\alpha\cos\beta - \sin\alpha\sin\beta.
\end{aligned} \tag{43}$$

Taking the ratio gives the tangent angle addition FORMULA

$$\tan(\alpha+\beta) \equiv \frac{\sin(\alpha+\beta)}{\cos(\alpha+\beta)} = \frac{\sin\alpha\cos\beta+\sin\beta\cos\alpha}{\cos\alpha\cos\beta-\sin\alpha\sin\beta}$$

$$= \frac{\frac{\sin\alpha}{\cos\alpha}+\frac{\sin\beta}{\cos\beta}}{1-\frac{\sin\alpha\sin\beta}{\cos\alpha\cos\alpha\beta}} = \frac{\tan\alpha+\tan\beta}{1-\tan\alpha\tan\beta}. \qquad (44)$$

The angle addition FORMULAS can also be derived purely algebraically without the use of COMPLEX NUMBERS. Consider the following figure.



From the large RIGHT TRIANGLE,

$$\sin(\alpha+\beta) = \frac{L\sin\beta+a}{L\cos\alpha+b} \qquad (45)$$

$$\cos(\alpha+\beta) = \frac{L\cos\beta}{L\cos\alpha+b}. \qquad (46)$$

But, from the small triangle (inset at upper right),

$$a = \frac{L\sin\alpha}{\cos(\alpha+\beta)} \qquad (47)$$

$$b = L\sin\alpha\tan(\alpha+\beta). \qquad (48)$$

Plugging a and b from (47) and (48) into (45) and (46) gives

$$\sin(\alpha+\beta) = \frac{L\sin\beta+\frac{L\sin\alpha}{\cos(\alpha+\beta)}}{L\cos\alpha+\frac{L\sin\alpha\sin(\alpha+\beta)}{\cos(\alpha+\beta)}}$$

$$= \frac{\sin\beta\cos(\alpha+\beta)+\sin\alpha}{\cos\alpha\cos(\alpha+\beta)+\sin\alpha\sin(\alpha+\beta)}, \qquad (49)$$

and

$$\cos(\alpha+\beta) = \frac{L\cos\beta}{L\cos\alpha+\frac{L\sin\alpha\sin(\alpha+\beta)}{\cos(\alpha+\beta)}}$$

$$= \frac{\cos\beta}{\cos\alpha+\frac{\sin\alpha\sin(\alpha+\beta)}{\cos(\alpha+\beta)}}. \qquad (50)$$

Now solve (50) for $\cos(\alpha+\beta)$,

$$\cos(\alpha+\beta)\cos\alpha+\sin\alpha\sin(\alpha+\beta) = \cos\beta \qquad (51)$$

to obtain

$$\cos(\alpha+\beta) = \frac{\cos\beta-\sin\alpha\sin(\alpha+\beta)}{\cos\alpha}. \qquad (52)$$

Plugging (52) into (49) gives

$$\sin(\alpha+\beta) = \frac{\sin\beta\left[\frac{\cos\beta-\sin\alpha\sin(\alpha+\beta)}{\cos\alpha}\right]+\sin\alpha}{\cos\alpha\left[\frac{\cos\beta-\sin\alpha\sin(\alpha+\beta)}{\cos\alpha}\right]+\sin\alpha\sin(\alpha+\beta)}$$

$$= \frac{\sin\beta\cos\beta-\sin\alpha\sin\beta\sin(\alpha+\beta)+\sin\alpha\cos\alpha}{\cos\alpha\cos\beta-\sin\alpha\cos\alpha\sin(\alpha+\beta)+\sin\alpha\cos\alpha\sin(\alpha+\beta)}$$

$$= \frac{\sin\beta\cos\beta-\sin\alpha\sin\beta\sin(\alpha+\beta)+\sin\alpha\cos\alpha}{\cos\alpha\cos\beta}$$

$$= \frac{\sin\alpha\cos\alpha+\sin\beta\cos\beta}{\cos\alpha\cos\beta}-\frac{\sin\alpha\sin\beta}{\cos\alpha\cos\beta}\sin(\alpha+\beta), \qquad (53)$$

so

$$\sin(\alpha+\beta)\left(1+\frac{\sin\alpha\sin\beta}{\cos\alpha\cos\beta}\right) = \frac{\sin\alpha\cos\alpha+\sin\beta\cos\beta}{\cos\alpha\cos\beta} \qquad (54)$$

$$\sin(\alpha+\beta)(\cos\alpha\cos\beta+\sin\alpha\sin\beta) = \sin\alpha\cos\alpha+\sin\beta\cos\beta, \qquad (55)$$

and

$$\sin(\alpha+\beta) = \frac{\sin\alpha\cos\alpha+\sin\beta\cos\beta}{\sin\alpha\sin\beta+\cos\alpha\cos\beta}$$

$$= \frac{\sin\alpha\cos\alpha+\sin\beta\cos\beta}{\sin\alpha\sin\beta+\cos\alpha\cos\beta}\,\frac{\sin\alpha\cos\beta+\sin\beta\cos\alpha}{\sin\alpha\cos\beta+\sin\beta\cos\alpha}. \qquad (56)$$

Multiplying out the DENOMINATOR gives

$$\begin{aligned}(\cos\alpha\cos\beta+\sin\alpha\sin\beta)(\sin\alpha\cos\beta+\sin\beta\cos\alpha) &= \sin\alpha\cos\alpha\cos^2\beta+\cos^2\alpha\sin\beta\cos\beta \\ &\quad+\sin^2\alpha\sin\beta\cos\beta+\sin\alpha\cos\alpha\sin^2\beta \\ &= \sin\alpha\cos\alpha+\sin\beta\cos\beta, \end{aligned} \qquad (57)$$

so

$$\sin(\alpha+\beta) = \sin\alpha\cos\beta+\sin\beta\cos\alpha. \qquad (58)$$

Multiplying out (50),

$$\cos(\alpha+\beta)\cos\alpha+\sin\alpha\sin(\alpha+\beta) = \cos\beta \qquad (59)$$

$$\begin{aligned}\cos(\alpha+\beta) &= \frac{\cos\beta-\sin\alpha\sin(\alpha+\beta)}{\cos\alpha} \\ &= \frac{\cos\beta-\sin\alpha(\sin\alpha\cos\beta+\sin\beta\cos\alpha)}{\cos\alpha} \\ &= \frac{\cos\beta(1-\sin^2\alpha)+\sin\alpha\cos\alpha\sin\beta}{\cos\alpha} \\ &= \frac{\cos^2\alpha\cos\beta+\sin\alpha\cos\alpha\sin\beta}{\cos\alpha} \\ &= \cos\alpha\cos\beta+\sin\alpha\sin\beta. \end{aligned} \qquad (60)$$

Summarizing,

$$\sin(\alpha+\beta) = \sin\alpha\cos\beta + \sin\beta\cos\alpha \quad (61)$$

$$\sin(\alpha-\beta) = \sin\alpha\cos\beta - \sin\beta\cos\alpha \quad (62)$$

$$\cos(\alpha+\beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta \quad (63)$$

$$\cos(\alpha-\beta) = \cos\alpha\cos\beta + \sin\alpha\sin\beta \quad (64)$$

$$\tan(\alpha+\beta) = \frac{\tan\alpha+\tan\beta}{1-\tan\alpha\tan\beta} \quad (65)$$

$$\tan(\alpha-\beta) = \frac{\tan\alpha-\tan\beta}{1+\tan\alpha\tan\beta}. \quad (66)$$

The sine and cosine angle addition identities can be summarized by the MATRIX EQUATION

$$\begin{bmatrix} \cos x & \sin x \\ -\sin x & \cos x \end{bmatrix} \begin{bmatrix} \cos y & \sin y \\ -\sin y & \cos y \end{bmatrix} = \begin{bmatrix} \cos(x+y) & \sin(x+y) \\ -\sin(x+y) & \cos(x+y) \end{bmatrix}. \quad (67)$$

The double angle formulas are

$$\sin(2\alpha) = 2\sin\alpha\cos\alpha \quad (68)$$

$$\cos(2\alpha) = \cos^2\alpha - \sin^2\alpha \quad (69)$$

$$= 2\cos^2\alpha - 1 \quad (70)$$

$$= 1 - 2\sin^2\alpha \quad (71)$$

$$\tan(2\alpha) = \frac{2\tan\alpha}{1-\tan^2\alpha}. \quad (72)$$

General multiple angle formulas are

$$\sin(n\alpha) = 2\sin[(n-1)\alpha]\cos\alpha - \sin[(n-2)\alpha] \quad (73)$$

$$\sin(nx) = n\cos^{n-1}x\sin x - \frac{n(n-1)(n-2)}{1\cdot2\cdot3}\cos^{n-3}x\sin^3 x + \ldots \quad (74)$$

$$\cos(n\alpha) = 2\cos[(n-1)\alpha]\cos\alpha - \cos[(n-2)\alpha] \quad (75)$$

$$\cos(nx) = \cos^n x - \frac{n(n-1)}{1\cdot2}\cos^{n-2}x\sin^2 x + \frac{n(n-1)(n-2)(n-3)}{1\cdot2\cdot3\cdot4}\cos^{n-4}x\sin^4 x - \ldots \quad (76)$$

$$\tan(n\alpha) = \frac{\tan[(n-1)\alpha]+\tan\alpha}{1-\tan[(n-1)\alpha]\tan\alpha}. \quad (77)$$

Therefore, any trigonometric function of a sum can be broken up into a sum of trigonometric functions with $\sin\alpha\cos\alpha$ cross terms. Particular cases for multiple angle formulas up to $n = 4$ are given below.

$$\sin(3\alpha) = 3\sin\alpha - 4\sin^3\alpha \quad (78)$$

$$\cos(3\alpha) = 4\cos^3\alpha - 3\cos\alpha \quad (79)$$

$$\tan(3\alpha) = \frac{3\tan\alpha - \tan^3\alpha}{1-3\tan^2\alpha} \quad (80)$$

$$\sin(4\alpha) = 4\sin\alpha\cos\alpha - 8\sin^3\alpha\cos\alpha \quad (81)$$

$$\cos(4\alpha) = 8\cos^4\alpha - 8\cos^2\alpha + 1 \quad (82)$$

$$\tan(4\alpha) = \frac{4\tan\alpha - 4\tan^3\alpha}{1-6\tan^2\alpha+\tan^4\alpha}. \quad (83)$$

Beyer (1987, p. 139) gives formulas up to $n = 6$.

Sum identities include

$$\frac{\tan(\alpha-\beta)}{\tan(\alpha+\beta)} = \frac{\sin(\alpha-\beta)\cos(\alpha+\beta)}{\cos(\alpha-\beta)\sin(\alpha+\beta)} = \frac{(\sin\alpha\cos\beta-\sin\beta\cos\alpha)(\cos\alpha\cos\beta-\sin\alpha\sin\beta)}{(\cos\alpha\cos\beta+\sin\alpha\sin\beta)(\sin\alpha\cos\beta+\sin\beta\cos\alpha)} = \frac{\sin\alpha\cos\alpha-\sin\beta\cos\beta}{\sin\alpha\cos\alpha+\sin\beta\cos\beta}. \quad (84)$$

Infinite sum identities include

$$\sum_{k=1,\ 3,\ 5,\ldots}^{\infty} \frac{e^{-kx}\sin(ky)}{k} = \frac{1}{2}\tan^{-1}\left(\frac{\sin y}{\sinh x}\right). \quad (85)$$

Trigonometric half-angle formulas include

$$\sin\left(\frac{\alpha}{2}\right) = \sqrt{\frac{1-\cos\alpha}{2}} \quad (86)$$

$$\cos\left(\frac{\alpha}{2}\right) = \sqrt{\frac{1+\cos\alpha}{2}} \quad (87)$$

$$\tan\left(\frac{\alpha}{2}\right) = \frac{\sin\alpha}{1+\cos\alpha} \quad (88)$$

$$= \frac{1-\cos\alpha}{\sin\alpha} \quad (89)$$

$$= \frac{1\pm\sqrt{1+\tan^2\alpha}}{\tan\alpha} \quad (90)$$

$$= \frac{\tan\alpha\sin\alpha}{\tan\alpha+\sin\alpha}. \quad (91)$$

The PROSTHAPHAERESIS FORMULAS are

$$\sin\alpha+\sin\beta = 2\sin[\tfrac{1}{2}(\alpha+\beta)]\cos[\tfrac{1}{2}(\alpha-\beta)] \quad (92)$$

$$\sin\alpha-\sin\beta = 2\cos[\tfrac{1}{2}(\alpha+\beta)]\sin[\tfrac{1}{2}(\alpha-\beta)] \quad (93)$$

$$\sin\alpha+\cos\beta = 2\cos[\tfrac{1}{2}(\alpha+\beta)]\cos[\tfrac{1}{2}(\alpha-\beta)] \quad (94)$$

$$\cos\alpha-\cos\beta = -2\sin[\tfrac{1}{2}(\alpha+\beta)]\sin[\tfrac{1}{2}(\alpha-\beta)]. \quad (95)$$

Related formulas are

$$\sin\alpha\cos\beta = \tfrac{1}{2}[\sin(\alpha-\beta)+\sin(\alpha+\beta)] \quad (96)$$

$$\cos\alpha\cos\beta = \tfrac{1}{2}[\cos(\alpha-\beta)+\cos(\alpha+\beta)] \quad (97)$$

$$\cos\alpha\sin\beta = \tfrac{1}{2}[\sin(\alpha+\beta)-\sin(\alpha-\beta)] \quad (98)$$

$$\sin\alpha\sin\beta = \tfrac{1}{2}[\cos(\alpha-\beta)-\cos(\alpha+\beta)]. \quad (99)$$

Multiplying both sides by 2 gives the equations sometimes known as the WERNER FORMULAS.

Trigonometric product/sum formulas are

$$\sin(\alpha+\beta)\sin(\alpha-\beta) = \sin^2\alpha - \sin^2\beta = \cos^2\beta - \cos^2\alpha \quad (100)$$

$$\cos(\alpha+\beta)\cos(\alpha-\beta) = \cos^2\alpha - \sin^2\beta = \cos^2\beta - \sin^2\alpha. \quad (101)$$

Power formulas include

$$\sin^2 x = \tfrac{1}{2}[1-\cos(2x)] \quad (102)$$
$$\sin^3 x = \tfrac{1}{4}[3\sin x - \sin(3x)] \quad (103)$$
$$\sin^4 x = \tfrac{1}{8}[3 - 4\cos(2x) + \cos(4x)] \quad (104)$$

and

$$\cos^2 x = \tfrac{1}{2}[1+\cos(2x)] \quad (105)$$
$$\cos^3 x = \tfrac{1}{4}[3\cos x + \cos(3x)] \quad (106)$$
$$\cos^4 x = \tfrac{1}{8}[3 + 4\cos(2x) + \cos(4x)] \quad (107)$$

(Beyer 1987, p. 140). Formulas of these types can also be given analytically as

$$\sin^{2n} x = \frac{1}{2^{2n}}\binom{2n}{n} + \frac{(-1)^n}{2^{2n-1}}\sum_{k=0}^{n-1}(-1)^k\binom{2n}{k}\cos[2(n-k)x] \quad (108)$$

$$\sin^{2n+1} = \frac{(-1)^n}{4^n}\sum_{k=0}^{n}(-1)^k\binom{2n+1}{k}\sin[(2n+1-2k)x] \quad (109)$$

$$\cos^{2n} x = \frac{(-1)^n}{2^{2n}}\binom{2n}{n} + \frac{1}{2^{2n-1}}\sum_{k=0}^{n-1}\binom{2n}{k}\cos[2(n-k)x] \quad (110)$$

$$\cos^{2n+1} x = \frac{1}{4^n}\sum_{k=0}^{n}\binom{2n+1}{k}\cos[(2n+1-2k)x] \quad (111)$$

(Kogan), where $\binom{n}{m}$ is a BINOMIAL COEFFICIENT.

Trigonometry Values—π

By the definition of the trigonometric functions,

$$\sin\pi = 0 \quad (1)$$
$$\cos\pi = -1 \quad (2)$$
$$\tan\pi = 0 \quad (3)$$
$$\csc\pi = \infty \quad (4)$$
$$\sec\pi = -1 \quad (5)$$
$$\cot\pi = \infty. \quad (6)$$

Trigonometry Values—π/2

By the definition of the trigonometric functions,

$$\sin\left(\frac{\pi}{2}\right) = 1 \quad (1)$$
$$\cos\left(\frac{\pi}{2}\right) = 0 \quad (2)$$
$$\tan\left(\frac{\pi}{2}\right) = \infty \quad (3)$$
$$\csc\left(\frac{\pi}{2}\right) = 1 \quad (4)$$
$$\sec\left(\frac{\pi}{2}\right) = \infty \quad (5)$$
$$\cot\left(\frac{\pi}{2}\right) = 0. \quad (6)$$

see also DIGON

Trigonometry Values—$\pi/3$

From TRIGONOMETRY VALUES: $\pi/6$

$$\sin\left(\frac{\pi}{6}\right) = \tfrac{1}{2} \tag{1}$$

$$\cos\left(\frac{\pi}{6}\right) = \tfrac{1}{2}\sqrt{3} \tag{2}$$

together with the trigonometric identity

$$\sin(2\alpha) = 2\sin\alpha\cos\alpha, \tag{3}$$

the identity

$$\sin\left(\frac{\pi}{3}\right) = 2\sin\left(\frac{\pi}{6}\right)\cos\left(\frac{\pi}{6}\right) = 2(\tfrac{1}{2})(\tfrac{1}{2}\sqrt{3}) = \tfrac{1}{2}\sqrt{3} \tag{4}$$

is obtained. Using the identity

$$\cos(2\alpha) = 1 - 2\sin^2\alpha, \tag{5}$$

then gives

$$\cos\left(\frac{\pi}{3}\right) = 1 - 2\sin^2\left(\frac{\pi}{6}\right) = 1 - 2(\tfrac{1}{2})^2 = \tfrac{1}{2}. \tag{6}$$

Summarizing,

$$\sin\left(\frac{\pi}{3}\right) = \tfrac{1}{2}\sqrt{3} \tag{7}$$

$$\cos\left(\frac{\pi}{3}\right) = \tfrac{1}{2} \tag{8}$$

$$\tan\left(\frac{\pi}{3}\right) = \sqrt{3}. \tag{9}$$

see also EQUILATERAL TRIANGLE

Trigonometry Values—$\pi/4$

For a RIGHT ISOSCELES TRIANGLE, symmetry requires that the angle at each VERTEX be given by

$$\tfrac{1}{2}\pi + 2\alpha = \pi, \tag{1}$$

so $\alpha = \pi/4$. The sides are equal, so

$$\sin^2\alpha + \cos^2\alpha = 2\sin^2\alpha = 1. \tag{2}$$

Solving,

$$\sin\left(\frac{\pi}{4}\right) = \tfrac{1}{2}\sqrt{2} \tag{3}$$

$$\cos\left(\frac{\pi}{4}\right) = \tfrac{1}{2}\sqrt{2} \tag{4}$$

$$\tan\left(\frac{\pi}{4}\right) = 1. \tag{5}$$

see also SQUARE

Trigonometry Values—$\pi/5$

Use the identity

$$\sin(5\alpha) = 5\sin\alpha - 20\sin^3\alpha + 16\sin^5\alpha. \tag{1}$$

Now, let $\alpha \equiv \pi/5$ and $x \equiv \sin\alpha$. Then

$$\sin\pi = 0 = 5x - 20x^3 + 16x^5 \tag{2}$$

$$16x^4 - 20x^2 + 5 = 0. \tag{3}$$

Solving the QUADRATIC EQUATION for x^2 gives

$$\begin{aligned}\sin^2\left(\frac{\pi}{5}\right) = x^2 &= \frac{20 \pm \sqrt{(-20)^2 - 4\cdot 16\cdot 5}}{2\cdot 16}\\ &= \frac{20 \pm \sqrt{80}}{32} = \tfrac{1}{8}(5 \pm \sqrt{5}\,).\end{aligned} \tag{4}$$

Now, $\sin(\pi/5)$ must be less than

$$\sin\left(\frac{\pi}{4}\right) = \tfrac{1}{2}\sqrt{2}, \tag{5}$$

so taking the MINUS SIGN and simplifying gives

$$\sin\left(\frac{\pi}{5}\right) = \sqrt{\frac{5-\sqrt{5}}{8}} = \tfrac{1}{4}\sqrt{10 - 2\sqrt{5}}. \tag{6}$$

$\cos(\pi/5)$ can be computed from

$$\cos\left(\frac{\pi}{5}\right) = \sqrt{1 - \sin^2\left(\frac{\pi}{5}\right)} = \tfrac{1}{4}(1 + \sqrt{5}). \tag{7}$$

Summarizing,

$$\sin\left(\frac{\pi}{5}\right) = \tfrac{1}{4}\sqrt{10 - 2\sqrt{5}} \tag{8}$$

$$\sin\left(\frac{2\pi}{5}\right) = \tfrac{1}{4}\sqrt{10 + 2\sqrt{5}} \tag{9}$$

$$\sin\left(\frac{3\pi}{5}\right) = \tfrac{1}{4}\sqrt{10 + 2\sqrt{5}} \tag{10}$$

$$\sin\left(\frac{4\pi}{5}\right) = \tfrac{1}{4}\sqrt{10 - 2\sqrt{5}} \tag{11}$$

$$\cos\left(\frac{\pi}{5}\right) = \tfrac{1}{4}(1 + \sqrt{5}) \tag{12}$$

$$\cos\left(\frac{2\pi}{5}\right) = \tfrac{1}{4}(-1 + \sqrt{5}\,) \tag{13}$$

$$\cos\left(\frac{3\pi}{5}\right) = \tfrac{1}{4}(1 - \sqrt{5}\,) \tag{14}$$

$$\cos\left(\frac{4\pi}{5}\right) = -\tfrac{1}{4}(1 + \sqrt{5}\,) \tag{15}$$

$$\tan\left(\frac{\pi}{5}\right) = \sqrt{5 - 2\sqrt{5}} \tag{16}$$

$$\tan\left(\frac{2\pi}{5}\right) = \sqrt{5 + 2\sqrt{5}} \tag{17}$$

$$\tan\left(\frac{3\pi}{5}\right) = -\sqrt{5 + 2\sqrt{5}} \tag{18}$$

$$\tan\left(\frac{4\pi}{5}\right) = -\sqrt{5 - 2\sqrt{5}}\,. \tag{19}$$

see also DODECAHEDRON, ICOSAHEDRON, PENTAGON, PENTAGRAM

Trigonometry Values—$\pi/6$

Given a RIGHT TRIANGLE with angles defined to be α and 2α, it must be true that

$$\alpha + 2\alpha + \tfrac{1}{2}\pi = \pi, \qquad (1)$$

so $\alpha = \pi/6$. Define the hypotenuse to have length 1 and the side opposite α to have length x, then the side opposite 2α has length $\sqrt{1-x^2}$. This gives $\sin\alpha \equiv x$ and

$$\sin(2\alpha) = \sqrt{1-x^2}. \qquad (2)$$

But

$$\sin(2\alpha) = 2\sin\alpha\cos\alpha = 2x\sqrt{1-x^2}, \qquad (3)$$

so we have

$$\sqrt{1-x^2} = 2x\sqrt{1-x^2}. \qquad (4)$$

This gives $2x = 1$, or

$$\sin\left(\frac{\pi}{6}\right) = \tfrac{1}{2}. \qquad (5)$$

$\cos(\pi/6)$ is then computed from

$$\cos\left(\frac{\pi}{6}\right) = \sqrt{1-\sin^2\left(\frac{\pi}{6}\right)} = \sqrt{1-(\tfrac{1}{2})^2} = \tfrac{1}{2}\sqrt{3}. \quad (6)$$

Summarizing,

$$\sin\left(\frac{\pi}{6}\right) = \tfrac{1}{2} \qquad (7)$$

$$\cos\left(\frac{\pi}{6}\right) = \tfrac{1}{2}\sqrt{3} \qquad (8)$$

$$\tan\left(\frac{\pi}{6}\right) = \tfrac{1}{3}\sqrt{3}. \qquad (9)$$

see also HEXAGON, HEXAGRAM

Trigonometry Values—$\pi/7$

Trigonometric functions of $n\pi/7$ for n an integer cannot be expressed in terms of sums, products, and finite root extractions on *real* rational numbers because 7 is not a FERMAT PRIME. This also means that the HEPTAGON is not a CONSTRUCTIBLE POLYGON.

However, exact expressions involving roots of *complex* numbers can still be derived using the trigonometric identity

$$\sin(n\alpha) = 2\sin[(n-1)\alpha]\cos\alpha - \sin[(n-2)\alpha]. \qquad (1)$$

The case $n = 7$ gives

$$\begin{aligned}\sin(7\alpha) &= 2\sin(6\alpha)\cos\alpha - \sin(5\alpha)\\ &= 2(32\cos^5\alpha\sin\alpha - 32\cos^3\alpha\sin\alpha + 6\cos\alpha\sin\alpha)\cos\alpha\\ &\quad -(5\sin\alpha - 20\sin^3\alpha + 16\sin^5\alpha)\\ &= 64\cos^6\alpha\sin\alpha - 64\cos^4\alpha\sin\alpha + 12\cos^2\alpha\sin\alpha\\ &\quad -5\sin\alpha + 20(1-\cos^2\alpha)\sin\alpha\\ &\quad -16(1-2\cos^2\alpha+\cos^4\alpha)\sin\alpha\\ &= \sin\alpha(64\cos^6\alpha - 80\cos^4\alpha + 24\cos^2\alpha - 1). \qquad (2)\end{aligned}$$

Rewrite this using the identity $\cos^2\alpha = 1 - \sin^2\alpha$,

$$\begin{aligned}\sin\left(\frac{\pi}{7}\right) &= \sin\alpha(7 - 56\sin^2\alpha + 112\sin^4\alpha - 64\sin^6\alpha)\\ &= -64\sin\alpha(\sin^6\alpha - \tfrac{112}{64}\sin^4\alpha + \tfrac{56}{64}\sin^2\alpha - \tfrac{7}{64}). \qquad (3)\end{aligned}$$

Now, let $\alpha \equiv \pi/7$ and $x \equiv \sin^2\alpha$, then

$$\sin(\pi) = 0 = x^3 - \tfrac{7}{4}x^2 + \tfrac{7}{8}x - \tfrac{7}{64}, \qquad (4)$$

which is a CUBIC EQUATION in x. The ROOTS are numerically found to be $x \approx 0.188255, 0.611260\ldots, 0.950484\ldots$. But $\sin\alpha = \sqrt{x}$, so these ROOTS correspond to $\sin\alpha \approx 0.4338$, $\sin(2\alpha) \approx 0.7817$, $\sin(3\alpha) \approx 0.9749$. By NEWTON'S RELATION

$$\prod_i r_i = -a_0, \qquad (5)$$

we have

$$x_1x_2x_3 = \tfrac{7}{64}, \qquad (6)$$

or

$$\sin\left(\frac{\pi}{7}\right)\sin\left(\frac{2\pi}{7}\right)\sin\left(\frac{3\pi}{7}\right) = \sqrt{\frac{7}{64}} = \tfrac{1}{8}\sqrt{7}. \qquad (7)$$

Similarly,

$$\cos\left(\frac{\pi}{7}\right)\cos\left(\frac{2\pi}{7}\right)\cos\left(\frac{3\pi}{7}\right) = \frac{1}{8}. \qquad (8)$$

The constants of the CUBIC EQUATION are given by

$$Q \equiv \tfrac{1}{9}(3a_1 - a_2{}^2) = \tfrac{1}{9}[3\cdot\tfrac{7}{8} - (-\tfrac{7}{4})^2] = -\tfrac{7}{144} \qquad (9)$$

$$\begin{aligned}R &\equiv \tfrac{1}{54}(9a_2a_1 - 2a_2^3 - 27a_0)\\ &= \tfrac{1}{54}[9(-\tfrac{7}{4})(\tfrac{1}{7}8) - 2(-\tfrac{7}{4})^3 - 27(-\tfrac{7}{64})]\\ &= -\tfrac{7}{3456}. \qquad (10)\end{aligned}$$

The DISCRIMINANT is then

$$\begin{aligned}D &\equiv Q^3 + R^2 = -\tfrac{343}{2{,}985{,}984} + \tfrac{49}{11{,}943{,}936}\\ &= -\tfrac{49}{442{,}368} < 0, \qquad (11)\end{aligned}$$

so there are three distinct REAL ROOTS. Finding the first one,

$$x = \sqrt[3]{R+\sqrt{D}} + \sqrt[3]{R-\sqrt{D}} - \tfrac{1}{3}a_2. \qquad (12)$$

Writing

$$\sqrt{D} = 3^{-3/2}\tfrac{7}{128}i, \qquad (13)$$

plugging in from above, and anticipating that the solution we have picked corresponds to $\sin(3\pi/7)$,

$$\sin\left(\frac{3\pi}{7}\right) = \sqrt{x} =$$

$$\sqrt{\sqrt[3]{-\frac{7}{3456} + 3^{-3/2}\frac{7}{128}i} + \sqrt[3]{-\frac{7}{3456} - 3^{-3/2}\frac{7}{128}i} - \frac{1}{3}\left(-\frac{7}{4}\right)}$$
$$= \sqrt{\sqrt[3]{-\frac{7}{3456} + 3^{-3/2}\frac{7}{128}i} + \sqrt[3]{-\frac{7}{3456} - 3^{-3/2}\frac{7}{128}i} + \frac{7}{12}}$$
$$= \sqrt{\sqrt[3]{\frac{7}{3456}\left(-1 + 3^{3/2}i\right)} - \sqrt[3]{\frac{7}{3456}\left(1 + 3^{3/2}i\right)} + \frac{7}{12}}$$
$$= \sqrt{\frac{1}{12}\left[\sqrt[3]{\frac{7}{2}\left(-1 + 3^{3/2}i\right)} - \sqrt[3]{\frac{7}{2}\left(1 + 3^{3/2}i\right)} + 7\right]}. \qquad (14)$$

see also HEPTAGON

Trigonometry Values—π/8

$$\sin\left(\frac{\pi}{8}\right) = \sin\left(\frac{1}{2}\cdot\frac{\pi}{4}\right) = \sqrt{\frac{1}{2}\left(1 - \cos\frac{\pi}{4}\right)}$$
$$= \sqrt{\tfrac{1}{2}\left(1 - \tfrac{1}{2}\sqrt{2}\right)} = \tfrac{1}{2}\sqrt{2 - \sqrt{2}}. \qquad (1)$$

Now, checking to see if the SQUARE ROOT can be simplified gives

$$a^2 - b^2c = 2^2 - 1^2 \cdot 2 = 4 - 2 = 2, \qquad (2)$$

which is not a PERFECT SQUARE, so the above expression cannot be simplified. Similarly,

$$\cos\left(\frac{\pi}{8}\right) = \cos\left(\frac{1}{2}\frac{\pi}{4}\right) = \sqrt{\frac{1}{2}\left(1 + \cos\frac{\pi}{4}\right)}$$
$$= \sqrt{\frac{1}{2}\left(1 + \frac{\sqrt{2}}{2}\right)} = \tfrac{1}{2}\sqrt{2 + \sqrt{2}} \qquad (3)$$

$$\tan\left(\frac{\pi}{8}\right) = \sqrt{\frac{2 - \sqrt{2}}{2 + \sqrt{2}}} = \sqrt{\frac{(2 - \sqrt{2})^2}{4 - 2}} = \sqrt{\frac{4 + 2 - 4\sqrt{2}}{2}}$$
$$= \sqrt{\frac{6 - 4\sqrt{2}}{2}} = \sqrt{3 - 2\sqrt{2}}. \qquad (4)$$

But

$$a^2 - b^2c = 3^2 - 2^2 2 = 9 - 8 = 1 \qquad (5)$$

is a PERFECT SQUARE, so we can find

$$d = \tfrac{1}{2}(3 \pm 1) = 1, 2.$$

Rewrite the above as

$$\tan\left(\frac{\pi}{8}\right) = \sqrt{2} - 1 \qquad (6)$$
$$\cot\left(\frac{\pi}{8}\right) = \frac{1}{\sqrt{2} - 1} = \frac{\sqrt{2} + 1}{2 - 1} = \sqrt{2} + 1. \qquad (7)$$

Summarizing,

$$\sin\left(\frac{\pi}{8}\right) = \tfrac{1}{2}\sqrt{2 - \sqrt{2}} \qquad (8)$$
$$\sin\left(\frac{3\pi}{8}\right) = \tfrac{1}{2}\sqrt{2 + \sqrt{2}} \qquad (9)$$
$$\cos\left(\frac{\pi}{8}\right) = \tfrac{1}{2}\sqrt{2 + \sqrt{2}} \qquad (10)$$
$$\cos\left(\frac{3\pi}{8}\right) = \tfrac{1}{2}\sqrt{2 - \sqrt{2}} \qquad (11)$$
$$\tan\left(\frac{\pi}{8}\right) = \sqrt{2} - 1 \qquad (12)$$
$$\tan\left(\frac{3\pi}{8}\right) = \sqrt{2} + 1. \qquad (13)$$

see also OCTAGON

Trigonometry Values—π/9

Trigonometric functions of $n\pi/9$ radians for n an integer not divisible by 3 (e.g., 40° and 80°) cannot be expressed in terms of sums, products, and finite root extractions on *real* rational numbers because 9 is not a product of distinct FERMAT PRIMES. This also means that the NONAGON is not a CONSTRUCTIBLE POLYGON.

However, exact expressions involving roots of *complex* numbers can still be derived using the trigonometric identity

$$\sin(3\alpha) = 3\sin\alpha - 4\sin^3\alpha. \qquad (1)$$

Let $\alpha \equiv \pi/9$ and $x \equiv \sin\alpha$. Then the above identity gives the CUBIC EQUATION

$$4x^3 - 3x + \tfrac{1}{2}\sqrt{3} = 0 \qquad (2)$$

$$x^3 - \tfrac{3}{4}x = -\tfrac{1}{8}\sqrt{3}. \qquad (3)$$

This cubic is of the form

$$x^3 + px = q, \qquad (4)$$

where

$$p = -\tfrac{3}{4} \qquad (5)$$
$$q = -\tfrac{1}{8}\sqrt{3}. \qquad (6)$$

The DISCRIMINANT is then

$$D \equiv \left(\frac{p}{3}\right)^3 + \left(\frac{q}{2}\right)^2$$
$$= \left(-\frac{1}{4}\right)^3 + \left(\frac{\sqrt{3}}{16}\right)^2 = -\frac{1}{16\cdot 4} + \frac{3}{16\cdot 16} = \frac{-4 + 3}{256}$$
$$= -\frac{1}{256} < 0. \qquad (7)$$

There are therefore three REAL distinct roots, which are approximately −0.9848, 0.3240, and 0.6428. We want the one in the first QUADRANT, which is 0.3240.

$$\begin{aligned}\sin\left(\frac{\pi}{9}\right) &= \sqrt[3]{-\frac{\sqrt{3}}{16}+\sqrt{-\frac{1}{256}}}+\sqrt[3]{-\frac{\sqrt{3}}{16}-\sqrt{-\frac{1}{256}}}\\ &= \sqrt[3]{-\frac{\sqrt{3}}{16}+\frac{1}{16}i}-\sqrt[3]{\frac{\sqrt{3}}{16}+\frac{1}{16}i}\\ &= 2^{-4/3}(\sqrt[3]{i-\sqrt{3}}-\sqrt[3]{i+\sqrt{3}})\\ &\approx 0.3240\ldots. \end{aligned} \tag{8}$$

Similarly,

$$\begin{aligned}\cos\left(\frac{\pi}{9}\right) &= 2^{-4/3}(\sqrt[3]{1+i\sqrt{3}}+\sqrt[3]{1-i\sqrt{3}})\\ &\approx 0.7660\ldots. \end{aligned} \tag{9}$$

Because of the NEWTON'S RELATIONS, we have the identities

$$\sin\left(\frac{\pi}{9}\right)\sin\left(\frac{2\pi}{9}\right)\sin\left(\frac{4\pi}{9}\right)=\tfrac{1}{8} \tag{10}$$

$$\cos\left(\frac{\pi}{9}\right)\cos\left(\frac{2\pi}{9}\right)\cos\left(\frac{4\pi}{9}\right)=\tfrac{1}{8}\sqrt{3} \tag{11}$$

$$\tan\left(\frac{\pi}{9}\right)\tan\left(\frac{2\pi}{9}\right)\tan\left(\frac{4\pi}{9}\right)=\sqrt{3}. \tag{12}$$

see also NONAGON, STAR OF GOLIATH

Trigonometry Values—$\pi/10$

$$\begin{aligned}\sin\left(\frac{\pi}{10}\right) &= \sin\left(\frac{1}{2}\cdot\frac{\pi}{5}\right)=\sqrt{\tfrac{1}{2}\left[1-\cos\left(\frac{\pi}{5}\right)\right]}\\ &= \sqrt{\tfrac{1}{2}[1-\tfrac{1}{4}(1+\sqrt{5})]}=\tfrac{1}{4}(\sqrt{5}-1). \end{aligned} \tag{1}$$

So we have

$$\begin{aligned}\cos\left(\frac{\pi}{10}\right) &= \cos\left(\frac{1}{2}\cdot\frac{\pi}{5}\right)=\sqrt{\frac{1}{2}\left[1+\cos\left(\frac{\pi}{5}\right)\right]}\\ &= \sqrt{\tfrac{1}{2}[1+\tfrac{1}{4}(1+\sqrt{5})]}\\ &= \tfrac{1}{4}\sqrt{10+2\sqrt{5}}, \end{aligned} \tag{2}$$

and

$$\tan\left(\frac{\pi}{10}\right)=\sqrt{\frac{3-\sqrt{5}}{5+\sqrt{5}}}=\tfrac{1}{5}\sqrt{25-10\sqrt{5}}. \tag{3}$$

Summarizing,

$$\sin\left(\frac{\pi}{10}\right)=\tfrac{1}{4}(\sqrt{5}-1) \tag{4}$$

$$\cos\left(\frac{\pi}{10}\right)=\tfrac{1}{4}\sqrt{10+2\sqrt{5}} \tag{5}$$

$$\tan\left(\frac{\pi}{10}\right)=\tfrac{1}{5}\sqrt{25-10\sqrt{5}} \tag{6}$$

$$\sin\left(\frac{3\pi}{10}\right)=\tfrac{1}{4}(1+\sqrt{5}) \tag{7}$$

$$\cos\left(\frac{3\pi}{10}\right)=\tfrac{1}{4}(10-2\sqrt{5}) \tag{8}$$

$$\tan\left(\frac{3\pi}{10}\right)=\tfrac{1}{5}\sqrt{25+10\sqrt{5}}. \tag{9}$$

An interesting near-identity is given by

$$\frac{1}{4}\left[\cos(\tfrac{1}{10})+\cosh(\tfrac{1}{10})+2\cos(\tfrac{1}{20}\sqrt{2})\cosh(\tfrac{1}{20}\sqrt{2})\right]\approx 1. \tag{10}$$

In fact, the left-hand side is approximately equal to $1+2.480\times 10^{-13}$.

see also DECAGON, DECAGRAM

Trigonometry Values—$\pi/11$

Trigonometric functions of $n\pi/11$ for n an integer cannot be expressed in terms of sums, products, and finite root extractions on *real* rational numbers because 11 is not a FERMAT PRIME. This also means that the UNDECAGON is not a CONSTRUCTIBLE POLYGON.

However, exact expressions involving roots of *complex* numbers can still be derived using the trigonometric identity

$$\begin{aligned}\sin(11\alpha) &= \sin(12\alpha-\alpha)\cos\alpha-\cos(12\alpha)\sin\alpha\\ &= 2\sin(6\alpha)\cos(6\alpha)\cos\alpha-[1-2\sin^2(6\alpha)]\sin\alpha. \end{aligned} \tag{1}$$

Using the identities from Beyer (1987, p. 139),

$$\sin(6\alpha)=\sin\alpha\cos\alpha[32\cos^4\alpha-32\cos^2\alpha+6] \tag{2}$$

$$\cos(6\alpha)=32\cos^6\alpha-48\cos^4\alpha+18\cos^2\alpha-1 \tag{3}$$

gives

$$\begin{aligned}\sin(11\alpha) &= 2\cos^2\alpha\sin\alpha(32\cos^4\alpha-32\cos^2\alpha+6)\\ &\quad\times(32\cos^6\alpha-48\cos^4\alpha+18\cos^2\alpha-1)\\ &\quad-\sin\alpha[1-2\sin^2\alpha\cos^2\alpha(32\cos^4\alpha-32\cos^2\alpha+6)^2]\\ &= \sin\alpha(11-220\sin^2\alpha+1232\sin^4\alpha\alpha\\ &\quad-2816\sin^6\alpha+2816\sin^8-1024\sin^{10}\alpha). \end{aligned} \tag{4}$$

Now, let $\alpha\equiv\pi/11$ and $x\equiv\sin^2\alpha$, then

$$\begin{aligned}\sin\pi &= 0\\ &= 11-220x+1232x^2-2816x^3+2816x^4-1024x^5. \end{aligned} \tag{5}$$

This equation is an irreducible QUINTIC EQUATION, so an analytic solution involving FINITE ROOT extractions does not exist. The numerical ROOTS are $x = 0.07937$, 0.29229, 0.57115, 0.82743, 0.97974. So $\sin\alpha = 0.2817$, $\sin(2\alpha) = 0.5406$, $\sin(3\alpha) = 0.7557$, $\sin(4\alpha) = 0.9096$, $\sin(5\alpha) = 0.9898$. From one of NEWTON'S IDENTITIES,

$$\sin\left(\frac{\pi}{11}\right)\sin\left(\frac{2\pi}{11}\right)\sin\left(\frac{3\pi}{11}\right)\sin\left(\frac{4\pi}{11}\right)\sin\left(\frac{5\pi}{11}\right) = \sqrt{\frac{11}{1024}} = \frac{\sqrt{11}}{32} \quad (6)$$

$$\cos\left(\frac{\pi}{11}\right)\cos\left(\frac{2\pi}{11}\right)\cos\left(\frac{3\pi}{11}\right)\cos\left(\frac{4\pi}{11}\right)\cos\left(\frac{5\pi}{11}\right) = \frac{1}{32} \quad (7)$$

$$\tan\left(\frac{\pi}{11}\right)\tan\left(\frac{2\pi}{11}\right)\tan\left(\frac{3\pi}{11}\right)\tan\left(\frac{4\pi}{11}\right)\tan\left(\frac{5\pi}{11}\right) = \sqrt{11}. \quad (8)$$

The trigonometric functions of $\pi/11$ also obey the identity

$$\tan\left(\frac{3\pi}{11}\right) + 4\sin\left(\frac{2\pi}{11}\right) = \sqrt{11}. \quad (9)$$

see also UNDECAGON

References

Beyer, W. H. "Trigonometry." *CRC Standard Mathematical Tables, 28th ed.* Boca Raton, FL: CRC Press, 1987.

Trigonometry Values—$\pi/12$

$$\begin{aligned}\sin\left(\frac{\pi}{12}\right) &= \sin\left(\frac{\pi}{3} - \frac{\pi}{4}\right)\\ &= -\sin\left(\frac{\pi}{4}\right)\cos\left(\frac{\pi}{3}\right) + \sin\left(\frac{\pi}{3}\right)\cos\left(\frac{\pi}{4}\right)\\ &= -\tfrac{1}{2}\sqrt{2}(\tfrac{1}{2}) + \tfrac{1}{2}\sqrt{3}(\tfrac{1}{2}\sqrt{2})\\ &= \tfrac{1}{4}(\sqrt{6} - \sqrt{2}). \quad (1)\end{aligned}$$

Similarly,

$$\begin{aligned}\cos\left(\frac{\pi}{12}\right) &= \cos\left(\frac{\pi}{3} - \frac{\pi}{4}\right)\\ &= \cos\left(\frac{\pi}{4}\right)\cos\left(\frac{\pi}{3}\right) - \sin\left(\frac{\pi}{3}\right)\sin\left(\frac{\pi}{4}\right)\\ &= \tfrac{1}{2}(\tfrac{1}{2}\sqrt{2}) + \tfrac{1}{2}\sqrt{3}(-\tfrac{1}{2}\sqrt{2})\\ &= \tfrac{1}{4}(\sqrt{6} + \sqrt{2}). \quad (2)\end{aligned}$$

Summarizing,

$$\sin\left(\frac{\pi}{12}\right) = \tfrac{1}{4}(\sqrt{6} - \sqrt{2}) \approx 0.25881 \quad (3)$$

$$\cos\left(\frac{\pi}{12}\right) = \tfrac{1}{4}(\sqrt{6} + \sqrt{2}) \approx 0.96592 \quad (4)$$

$$\tan\left(\frac{\pi}{12}\right) = 2 - \sqrt{3} \approx 0.26794 \quad (5)$$

$$\csc\left(\frac{\pi}{12}\right) = \sqrt{6} + \sqrt{2} \approx 3.86370 \quad (6)$$

$$\sec\left(\frac{\pi}{12}\right) = \sqrt{6} - \sqrt{2} \approx 1.03527 \quad (7)$$

$$\cot\left(\frac{\pi}{12}\right) = 2 + \sqrt{3} \approx 3.73205. \quad (8)$$

Trigonometry Values—$\pi/15$

$$\begin{aligned}\sin\left(\frac{\pi}{15}\right) &= \sin\left(\frac{\pi}{6} - \frac{\pi}{10}\right)\\ &= \sin\left(\frac{\pi}{6}\right)\cos\left(\frac{\pi}{10}\right) - \sin\left(\frac{\pi}{10}\right)\cos\left(\frac{\pi}{6}\right)\\ &= \frac{1}{2}\sqrt{\frac{1}{8}(5+\sqrt{5})} - \frac{\sqrt{3}}{2}\frac{1}{4}(\sqrt{5} - 1)\\ &= \tfrac{1}{16}(2\sqrt{3} - 2\sqrt{15} + \sqrt{40 + 8\sqrt{5}}) \quad (1)\end{aligned}$$

and

$$\begin{aligned}\cos\left(\frac{\pi}{15}\right) &= \cos\left(\frac{\pi}{6} - \frac{\pi}{10}\right)\\ &= \cos\left(\frac{\pi}{6}\right)\cos\left(\frac{\pi}{10}\right) + \sin\left(\frac{\pi}{6}\right)\sin\left(\frac{\pi}{10}\right)\\ &= \frac{\sqrt{3}}{2}\sqrt{\frac{1}{8}(5+\sqrt{5})} + \frac{1}{2}\frac{1}{4}(\sqrt{5} - 1)\\ &= \tfrac{1}{8}(\sqrt{30 + 6\sqrt{5}} + \sqrt{5} - 1). \quad (2)\end{aligned}$$

Summarizing,

$$\begin{aligned}\sin\left(\frac{\pi}{15}\right) &= \tfrac{1}{16}(2\sqrt{3} - 2\sqrt{15} + \sqrt{40 + 8\sqrt{5}})\\ &\approx 0.20791 \quad (3)\end{aligned}$$

$$\begin{aligned}\sin\left(\frac{2\pi}{15}\right) &= \tfrac{1}{8}(\sqrt{3} + \sqrt{15} - \sqrt{10 - 2\sqrt{5}})\\ &\approx 0.40673 \quad (4)\end{aligned}$$

$$\cos\left(\frac{\pi}{15}\right) = \tfrac{1}{8}(\sqrt{30 + 6\sqrt{5}} + \sqrt{5} - 1) \approx 0.97814 \quad (5)$$

$$\cos\left(\frac{2\pi}{15}\right) = \tfrac{1}{8}(\sqrt{30 - 6\sqrt{5}} + 1) \approx 0.91354 \quad (6)$$

$$\begin{aligned}\tan\left(\frac{\pi}{15}\right) &= \tfrac{1}{2}(3\sqrt{3} - \sqrt{15} - \sqrt{50 - 22\sqrt{5}})\\ &\approx 0.21255. \quad (7)\end{aligned}$$

Trigonometry Values—$\pi/16$

$$\begin{aligned}\sin\left(\frac{\pi}{16}\right) &= \sin\left(\frac{1}{2}\cdot\frac{\pi}{8}\right)\\ &= \sqrt{\tfrac{1}{2}\left(1 - \cos\frac{\pi}{8}\right)} = \sqrt{\tfrac{1}{2}\left(1 - \tfrac{1}{2}\sqrt{2+\sqrt{2}}\right)}\\ &= \sqrt{\tfrac{1}{2} - \tfrac{1}{4}\sqrt{2+\sqrt{2}}} = \tfrac{1}{2}\sqrt{2 - \sqrt{2+\sqrt{2}}} \quad (1)\end{aligned}$$

$$\begin{aligned}\cos\left(\frac{\pi}{16}\right) &= \cos\left(\frac{1}{2}\cdot\frac{\pi}{8}\right)\\ &= \sqrt{\frac{1}{2}\left(1 + \cos\frac{\pi}{8}\right)} = \sqrt{\tfrac{1}{2}\left(1 + \tfrac{1}{2}\sqrt{2+\sqrt{2}}\right)}\\ &= \sqrt{\tfrac{1}{2} + \tfrac{1}{4}\sqrt{2+\sqrt{2}}} = \tfrac{1}{2}\sqrt{2 + \sqrt{2+\sqrt{2}}} \quad (2)\end{aligned}$$

$$\begin{aligned}\tan\left(\frac{\pi}{16}\right) &= \sqrt{\frac{2 - \sqrt{2+\sqrt{2}}}{2 + \sqrt{2+\sqrt{2}}}}\\ &= \sqrt{4 + 2\sqrt{2}} - \sqrt{2} - 1. \quad (3)\end{aligned}$$

Summarizing,

$$\sin\left(\frac{\pi}{16}\right) = \tfrac{1}{2}\sqrt{2-\sqrt{2+\sqrt{2}}} \approx 0.19509 \tag{4}$$

$$\sin\left(\frac{3\pi}{16}\right) = \tfrac{1}{2}\sqrt{2-\sqrt{2-\sqrt{2}}} \approx 0.55557 \tag{5}$$

$$\cos\left(\frac{\pi}{16}\right) = \tfrac{1}{2}\sqrt{2+\sqrt{2+\sqrt{2}}} \approx 0.98079 \tag{6}$$

$$\cos\left(\frac{3\pi}{16}\right) = \tfrac{1}{2}\sqrt{2+\sqrt{2-\sqrt{2}}} \approx 0.83147 \tag{7}$$

$$\tan\left(\frac{\pi}{16}\right) = \sqrt{4+2\sqrt{2}} - \sqrt{2} - 1 \approx 0.19891. \tag{8}$$

Trigonometry Values—$\pi/17$

Rather surprisingly, trigonometric functions of $n\pi/17$ for n an integer can be expressed in terms of sums, products, and finite root extractions because 17 is a FERMAT PRIME. This makes the HEPTADECAGON a CONSTRUCTIBLE, as first proved by Gauss. Although Gauss did not actually explicitly provide a construction, he did derive the trigonometric formulas below using a series of intermediate variables from which the final expressions were then built up.

Let

$$\epsilon \equiv \sqrt{17+\sqrt{17}}$$

$$\epsilon^* \equiv \sqrt{17-\sqrt{17}}$$

$$\alpha \equiv \sqrt{\sqrt{34}+6\sqrt{17}+(\sqrt{34}-\sqrt{2}\,)\epsilon^* - 8\sqrt{2}\,\epsilon}$$

$$\beta \equiv 2\sqrt{17+3\sqrt{17}-2\sqrt{2}\,\epsilon-\sqrt{2}\,\epsilon^*}\,.$$

Then

$$\sin\left(\frac{\pi}{17}\right) = \tfrac{1}{8}[34 - 2\sqrt{17} - 2\sqrt{2}\,\epsilon^* - 2\sqrt{68+12\sqrt{17}+2\sqrt{2}(\sqrt{17}-1)\epsilon^* - 16\sqrt{2}\,\epsilon}\,]^{1/2} \approx 0.18375$$

$$\cos\left(\frac{\pi}{17}\right) = \tfrac{1}{8}[30 + 2\sqrt{17} + 2\sqrt{2}\,\epsilon^* + 2\sqrt{68+12\sqrt{17}+2\sqrt{2}(\sqrt{17}-1)\epsilon^* - 16\sqrt{2}\,\epsilon}\,]^{1/2} \approx 0.98297$$

$$\sin\left(\frac{2\pi}{17}\right) = \tfrac{1}{16}[136 - 8\sqrt{17} + 4\sqrt{2}(1-\sqrt{17})\epsilon^* + 16\sqrt{2}\,\epsilon + 2(\sqrt{2}-\sqrt{34}-2\epsilon^*)\sqrt{34+6\sqrt{17}+(\sqrt{34}-\sqrt{2})\epsilon^* - 8\sqrt{2}\epsilon}\,]^{1/2} \approx 0.36124$$

$$\cos\left(\frac{2\pi}{17}\right) = \tfrac{1}{16}[-1 + \sqrt{17} + \sqrt{2}\epsilon^* + \sqrt{68+12\sqrt{17}-2\sqrt{2}(1-\sqrt{17}\,)\epsilon^* - 16\sqrt{2}\,\epsilon}\,] \approx 0.0.93247$$

$$\sin\left(\frac{4\pi}{17}\right) = \tfrac{1}{128}(-\sqrt{2}+\sqrt{34}+2\epsilon^*+2\alpha) \times\sqrt{68-4\sqrt{17}-2(\sqrt{34}-\sqrt{2}\,)\epsilon^* + 8\sqrt{2}\,\epsilon + \alpha(\sqrt{2}-\sqrt{34}-2\epsilon^*)} \approx 0.0.67370$$

$$\sin\left(\frac{8\pi}{17}\right) = \tfrac{1}{16}[136 - 8\sqrt{17} + 8\sqrt{2}\epsilon - 2(\sqrt{34}-3\sqrt{2})\epsilon^* - 2\beta(1-\sqrt{17}-\sqrt{2}\epsilon^*)\,]^{1/2} \approx 0.99573$$

$$\cos\left(\frac{8\pi}{17}\right) = \tfrac{1}{16}(-1+\sqrt{17}+\sqrt{2}\,\epsilon^* - 2\sqrt{17+3\sqrt{17}-\sqrt{2}\,\epsilon^*-2\sqrt{2}\,\epsilon}\,). \approx 0.09227$$

There are some interesting analytic formulas involving the trigonometric functions of $n\pi/17$. Define

$$P(x) \equiv (x-1)(x-2)(x^2+1)$$

$$g_1(x) \equiv \frac{2+\sqrt{P(x)}}{1-x}$$

$$g_4(x) \equiv \frac{2-\sqrt{P(x)}}{1-x}$$

$$f_i(x) \equiv \tfrac{1}{4}[g_i(x)-1]$$

$$a \equiv \tfrac{1}{4}\tan^{-1}4,$$

where $i = 1$ or 4. Then

$$f_1(\tan a) = \cos\left(\frac{2\pi}{17}\right)$$

$$f_4(\tan a) = \cos\left(\frac{8\pi}{17}\right).$$

Trigonometry Values—$\pi/18$

The exact values of $\cos(\pi/18)$ and $\sin(\pi/18)$ are given by infinite NESTED RADICALS.

$$\sin\left(\frac{\pi}{18}\right) = \tfrac{1}{2}\sqrt{2-\sqrt{2+\sqrt{2+\sqrt{2-\ldots}}}} \approx 0.17365,$$

where the sequence of signs $+$, $+$, $-$ repeats with period 3, and

$$\cos\left(\frac{\pi}{18}\right) = \tfrac{1}{6}\sqrt{3}\left(\sqrt{8-\sqrt{8-\sqrt{8+\sqrt{8-\ldots}}}}+1\right) \approx 0.98481,$$

where the sequence of signs $-$, $-$, $+$ repeats with period 3.

Trigonometry Values—$\pi/20$

$$\begin{aligned}\sin\left(\frac{\pi}{20}\right) &= \sin\left(\frac{1}{2}\frac{\pi}{10}\right) = \sqrt{\frac{1}{2}\left(1-\cos\frac{\pi}{10}\right)}\\ &= \tfrac{1}{4}\sqrt{8-2\sqrt{10+2\sqrt{5}}}\\ &\approx 0.15643\ldots \qquad (1)\\ \cos\left(\frac{\pi}{20}\right) &= \cos\left(\frac{1}{2}\frac{\pi}{10}\right) = \sqrt{\frac{1}{2}\left(1+\cos\frac{\pi}{10}\right)}\\ &= \tfrac{1}{4}\sqrt{8+2\sqrt{10+2\sqrt{5}}}\\ &\approx 0.98768\ldots \qquad (2)\\ \tan\left(\frac{\pi}{20}\right) &= 1+\sqrt{5}-\sqrt{5+2\sqrt{5}}\\ &\approx 0.15838. \qquad (3)\end{aligned}$$

An interesting near-identity is given by

$$\frac{1}{4}\left[\cos(\tfrac{1}{10})+\cosh(\tfrac{1}{10})+2\cos(\tfrac{1}{20}\sqrt{2})\cosh(\tfrac{1}{20}\sqrt{2})\right]\approx 1. \qquad (4)$$

In fact, the left-hand side is approximately equal to $1 + 2.480 \times 10^{-13}$.

Trigonometry Values—0

By the definition of the trigonometric functions,

$$\begin{aligned}\sin 0 &= 0\\ \cos 0 &= 1\\ \tan 0 &= 0\\ \csc 0 &= \infty\\ \sec 0 &= 1\\ \cot 0 &= \infty.\end{aligned}$$

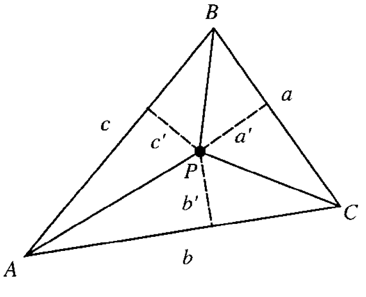
Trihedron

The TRIPLE of unit ORTHOGONAL VECTORS **T**, **N**, and **B** (TANGENT VECTOR, NORMAL VECTOR, and BINORMAL VECTOR).

see also BINORMAL VECTOR, NORMAL VECTOR, TANGENT VECTOR

Trilinear Coordinates



Given a TRIANGLE ΔABC, the trilinear coordinates of a point P with respect to ΔABC are an ordered TRIPLE of numbers, each of which is PROPORTIONAL to the directed distance from P to one of the side lines. Trilinear coordinates are denoted $\alpha : \beta : \gamma$ or (α, β, γ) and also are known as BARYCENTRIC COORDINATES, HOMOGENEOUS COORDINATES, or "trilinears."

In trilinear coordinates, the three VERTICES A, B, and C are given by $1:0:0$, $0:1:0$, and $0:0:1$. Let the point P in the above diagram have trilinear coordinates $\alpha : \beta : \gamma$ and lie at distances a', b', and c' from the sides BC, AC, and AB, respectively. Then the distances $a' = k\alpha$, $b' = k\beta$, and $c' = k\gamma$ can be found by writing Δ_a for the AREA of ΔBPC, and similarly for Δ_b and Δ_c. We then have

$$\begin{aligned}\Delta &= \Delta_a + \Delta_b + \Delta_c = \tfrac{1}{2}aa' + \tfrac{1}{2}bb' + \tfrac{1}{2}cc'\\ &= \tfrac{1}{2}(ak\alpha + bk\beta + ck\gamma) = \tfrac{1}{2}k(a\alpha + b\beta + c\gamma). \qquad (1)\end{aligned}$$

so

$$k \equiv \frac{2\Delta}{a\alpha + b\beta + c\gamma}, \qquad (2)$$

where Δ is the AREA of ΔABC and a, b, and c are the lengths of its sides. When the values of the coordinates are taken as the actual lengths (i.e., the trilinears are chosen so that $k = 1$), the coordinates are known as EXACT TRILINEAR COORDINATES.

Trilinear coordinates are unchanged when each is multiplied by any constant μ, so

$$t_1 : t_2 : t_3 = \mu t_1 : \mu t_2 : \mu t_3. \qquad (3)$$

When normalized so that

$$t_1 + t_2 + t_3 = 1, \qquad (4)$$

trilinear coordinates are called AREAL COORDINATES. The trilinear coordinates of the line

$$ux + vy + wz = 0 \qquad (5)$$

are

$$u : v : w = ad_A : bd_B : cd_C, \qquad (6)$$

where d_i is the POINT-LINE DISTANCE from VERTEX A to the LINE.

Trilinear coordinates for some common POINTS are summarized in the following table, where A, B, and C are the angles at the corresponding vertices and a, b, and c are the opposite side lengths.

Point	Triangle Center Function
centroid M	$\csc A$, $1/a$
circumcenter O	$\cos A$
de Longchamps point	$\cos A - \cos B \cos C$
equal detour point	$\sec(\frac{1}{2}A)\cos(\frac{1}{2}B)\cos(\frac{1}{2}C)+1$
Feuerbach point F	$1-\cos(B-C)$
incenter I	1
isoperimetric point	$\sec(\frac{1}{2}A)\cos(\frac{1}{2}B)\cos(\frac{1}{2}C)-1$
Lemoine point	a
nine-point center N	$\cos(B-C)$
orthocenter H	$\cos B \cos C$
vertex A	$1:0:0$
vertex B	$0:1:0$
vertex C	$0:0:1$

To convert trilinear coordinates to a vector position for a given triangle specified by the x- and y-coordinates of its axes, pick two UNIT VECTORS along the sides. For instance, pick

$$\hat{\mathbf{a}} = \begin{bmatrix} a_1 \\ a_2 \end{bmatrix} \tag{7}$$

$$\hat{\mathbf{c}} = \begin{bmatrix} c_1 \\ c_2 \end{bmatrix}, \tag{8}$$

where these are the UNIT VECTORS BC and AB. Assume the TRIANGLE has been labeled such that $A = \mathbf{x}_1$ is the lower rightmost VERTEX and $C = \mathbf{x}_2$. Then the VECTORS obtained by traveling l_a and l_c along the sides and then inward PERPENDICULAR to them must meet

$$\begin{bmatrix} x_1 \\ y_1 \end{bmatrix} + l_c \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} - k\gamma \begin{bmatrix} c_2 \\ -c_1 \end{bmatrix} = \begin{bmatrix} x_2 \\ y_2 \end{bmatrix} + l_a \begin{bmatrix} a_1 \\ a_2 \end{bmatrix} - k\alpha \begin{bmatrix} a_2 \\ -a_1 \end{bmatrix}. \tag{9}$$

Solving the two equations

$$x_1 + l_c c_1 - k\gamma c_2 = x_2 l_a a_1 - k\alpha a_2 \tag{10}$$

$$y_1 + l_c c_2 + k\gamma c_1 = y_2 l_a a_2 + k\alpha a_1, \tag{11}$$

gives

$$l_c = \frac{k\alpha(a_1c_1+a_2c_2) - \gamma k({c_1}^2+{c_2}^2) + c_2(x_1-x_2) + c_1(y_2-y_1)}{a_1c_2 - a_2c_1} \tag{12}$$

$$l_a = \frac{k\alpha({a_1}^2+{a_2}^2) - \gamma k(a_1c_1+a_2c_2) + a_2(x_1-x_2) + a_1(y_2-y_1)}{a_1c_2 - a_2c_1}. \tag{13}$$

But $\hat{\mathbf{a}}$ and $\hat{\mathbf{c}}$ are UNIT VECTORS, so

$$l_c = \frac{k\alpha(a_1c_1+a_2c_2) - \gamma k + c_2(x_1-x_2) + c_1(y_2-y_1)}{a_1c_2 - a_2c_1} \tag{14}$$

$$l_a = \frac{k\alpha - \gamma k(a_1c_1+a_2c_2) + a_2(x_1-x_2) + a_1(y_2-y_1)}{a_1c_2 - a_2c_1}. \tag{15}$$

And the VECTOR coordinates of the point $\alpha : \beta : \gamma$ are then

$$\mathbf{x} = \mathbf{x}_1 + l_c \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} - k\gamma \begin{bmatrix} c_2 \\ -c_1 \end{bmatrix}. \tag{16}$$

Trilinear Line

A LINE is given in TRILINEAR COORDINATES by

$$l\alpha + m\beta + n\gamma = 0.$$

see also LINE, TRILINEAR COORDINATES

Trilinear Polar

Given a TRIANGLE CENTER $X = l : m : n$, the line

$$l\alpha + m\beta + n\gamma = 0$$

is called the trilinear polar of X^{-1} and is denoted L.

see also CHASLES'S POLARS THEOREM

Trillion

The word trillion denotes different numbers in American and British usage. In the American system, one trillion equals 10^{12}. In the British, French, and German systems, one trillion equals 10^{18}.

see also BILLION, LARGE NUMBER, MILLION

Trimagic Square

If replacing each number by its square or cube in a MAGIC SQUARE produces another MAGIC SQUARE, the square is said to be a trimagic square. Trimagic squares of order 32, 64, 81, and 128 are known. Tarry gave a method for constructing a trimagic square of order 128, Cazalas a method for trimagic squares of orders 64 and 81, and R. V. Heath a method for constructing an order 64 trimagic square which is different from Cazalas's (Kraitchik 1942).

Trimagic squares are also called TREBLY MAGIC SQUARES, and are 3-MULTIMAGIC SQUARES.

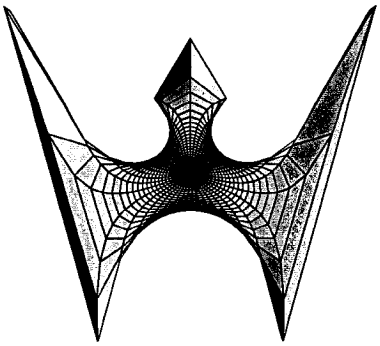
Trinoid



A MINIMAL SURFACE discovered by L. P. M. Jorge and W. Meeks III in 1983 with ENNEPER-WEIERSTRAß PARAMETERIZATION

$$f = \frac{1}{(\zeta^3 - 1)^2} \tag{1}$$

$$g = \zeta^2 \tag{2}$$

(Dickson 1990). Explicitly, it is given by

$$x = \Re\left[\frac{re^{i\theta}}{3(1 + re^{i\theta} + r^2e^{2i\theta})} - \frac{4\ln(re^{i\theta} - 1)}{9} + \frac{2\ln(1 + re^{i\theta} + r^2e^{2i\theta})}{9}\right] \tag{3}$$

$$y = -\tfrac{1}{9}\Im\left[\frac{-3re^{i\theta}(1 + re^{i\theta})}{r^3e^{3i\theta} - 1} + \frac{4\sqrt{3}\,(r^3e^{3i\theta} - 1)\tan^{-1}\left(\frac{1+2re^{i\theta}}{\sqrt{3}}\right)}{r^3e^{3i\theta} - 1}\right] \tag{4}$$

$$z = \Re\left[-\frac{2}{3} - \frac{2}{3(r^3e^{3i\theta} - 1)}\right], \tag{5}$$

for $\theta \in [0, 2\pi)$ and $r \in [0, 4]$.

Trinomial

A POLYNOMIAL with three terms.

see also BINOMIAL, MONOMIAL, POLYNOMIAL

Trinomial Identity

$$(x^2 + axy + by^2)(t^2 + atu + bu^2) = r^2 + ars + bs^2, \tag{1}$$

where

$$r = xt - byu \tag{2}$$

$$s = yt + xu + ayu. \tag{3}$$

Trinomial Triangle

The NUMBER TRIANGLE obtained by starting with a row containing a single "1" and the next row containing three 1s and then letting subsequent row elements be computed by summing the elements above to the left, directly above, and above to the right:

$$\begin{array}{ccccccccc} & & & & 1 & & & & \\ & & & 1 & 1 & 1 & & & \\ & & 1 & 2 & 3 & 2 & 1 & & \\ & 1 & 3 & 6 & 7 & 6 & 3 & 1 & \\ 1 & 4 & 10 & 16 & 19 & 16 & 10 & 4 & 1 \end{array}$$

(Sloane's A027907). The nth row can also be obtained by expanding $(1+x+x^2)^n$ and taking coefficients:

$$\begin{aligned} (1+x+x^2)^0 &= 1 \\ (1+x+x^2)^1 &= 1+x+x^2 \\ (1+x+x^2)^2 &= 1+2x+3x^2+2x^3+x^4 \end{aligned}$$

and so on.

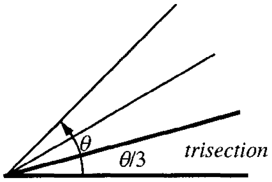
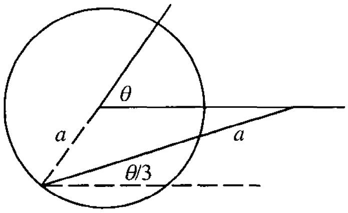
Trisection



Angle trisection is the division of an *arbitrary* ANGLE into three equal ANGLES. It was one of the three GEOMETRIC PROBLEMS OF ANTIQUITY for which solutions using only COMPASS and STRAIGHTEDGE were sought. The problem was algebraically proved impossible by Wantzel (1836).

Although trisection is not possible for a general ANGLE using a Greek construction, there are some specific angles, such as $\pi/2$ and π radians (90° and 180°, respectively), which *can* be trisected. Furthermore, some ANGLES are geometrically trisectable, but cannot be constructed in the first place, such as $3\pi/7$ (Honsberger 1991). In addition, trisection of an arbitrary angle *can* be accomplished using a *marked* RULER (a NEUSIS CONSTRUCTION) as illustrated below (Courant and Robbins 1996).



An ANGLE can also be divided into three (or any WHOLE NUMBER) of equal parts using the QUADRATRIX OF HIPPIAS or TRISECTRIX.

Tritangent Triangle

see EXCENTRAL TRIANGLE

Trivial

According to the Nobel Prize-winning physicist Richard Feynman (1985), mathematicians designate any THEOREM as "trivial" once a proof has been obtained—no matter how difficult the theorem was to prove in the first place. There are therefore exactly two types of true mathematical propositions: trivial ones, and those which have not yet been proven.

see also PROOF, THEOREM

References

Feynman, R. P. and Leighton, R. *Surely You're Joking, Mr. Feynman!* New York: Bantam Books, 1985.

Trivialization

In the definition of a FIBER BUNDLE $f : E \to B$, the homeomorphisms $g_U : f^{-1}(U) \to U \times F$ that commute with projection are called local trivializations for the FIBER BUNDLE f.

see also FIBER BUNDLE

Trochoid

The curve described by a point at a distance b from the center of a rolling CIRCLE of RADIUS a.

$$x = a\phi - b\sin\phi$$
$$y = a - b\cos\phi.$$

If $b < a$, the curve is a CURTATE CYCLOID. If $b = a$, the curve is a CYCLOID. If $b > a$, the curve is a PROLATE CYCLOID.

Tromino

see TRIOMINO

True

A statement which is rigorously known to be correct. A statement which is not true is called FALSE, although certain statements can be proved to be rigorously UNDECIDABLE within the confines of a given set of assumptions and definitions. Regular two-valued LOGIC allows statements to be only true or FALSE, but FUZZY LOGIC treats "truth" as a continuum which can have any value between 0 and 1.

see also ALETHIC, FALSE, FUZZY LOGIC, LOGIC, TRUTH TABLE, UNDECIDABLE

Truncate

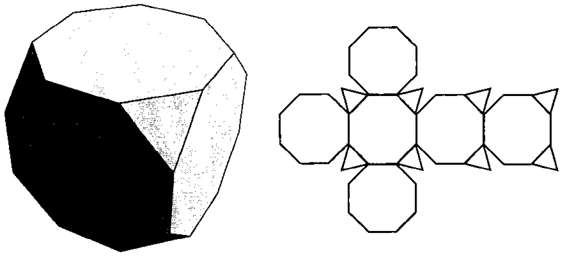
To truncate a REAL NUMBER is to remove its nonintegral part. Truncation of a number x therefore corresponds to taking the FLOOR FUNCTION $\lfloor x \rfloor$.

see also CEILING FUNCTION, FLOOR FUNCTION, NINT, ROUND

Truncated Cone

see CONICAL FRUSTUM

Truncated Cube



An ARCHIMEDEAN SOLID whose DUAL POLYHEDRON is the TRIAKIS OCTAHEDRON. It has SCHLÄFLI SYMBOL t{4,3}. It is also UNIFORM POLYHEDRON U_9 and has WYTHOFF SYMBOL $2\,3\,|\,4$. Its faces are $8\{3\}+6\{8\}$. The INRADIUS, MIDRADIUS, and CIRCUMRADIUS for $a = 1$ are

$$r = \tfrac{1}{17}(5 + 2\sqrt{2})\sqrt{7 + 4\sqrt{2}} \approx 1.63828$$
$$\rho = \tfrac{1}{2}(2 + \sqrt{2}) \approx 1.70711$$
$$R = \tfrac{1}{2}\sqrt{7 + 4\sqrt{2}} \approx 1.77882.$$

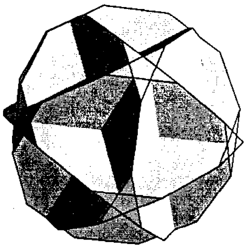
Truncated Great Dodecahedron



The UNIFORM POLYHEDRON U_{37} whose DUAL POLYHEDRON is the SMALL STELLAPENTAKIS DODECAHEDRON. It has SCHLÄFLI SYMBOL $t\{5, \frac{5}{2}\}$. It has WYTHOFF SYMBOL $2\ \frac{5}{2}\ 5$. Its faces are $12\{\frac{5}{2}\} + 12\{10\}$. Its CIRCUMRADIUS for $a = 1$ is

$$R = \tfrac{1}{4}\sqrt{34 + 10\sqrt{5}}.$$

see also GREAT ICOSAHEDRON

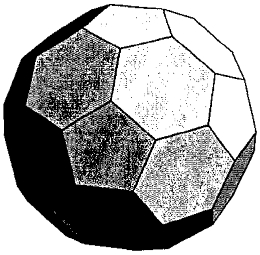
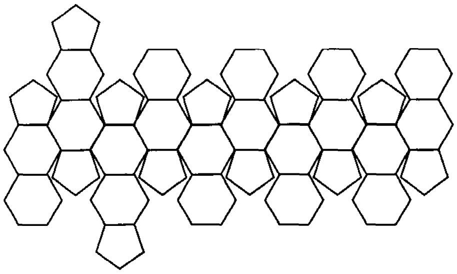
Truncated Icosahedron





An ARCHIMEDEAN SOLID used in the construction of SOCCER BALLS. Its DUAL POLYHEDRON is the PENTAKIS DODECAHEDRON. It has SCHLÄFLI SYMBOL t{3, 5}. It is also UNIFORM POLYHEDRON U_{25} and has WYTHOFF SYMBOL 2 5 | 3. Its faces are 20{6} + 12{5}. The INRADIUS, MIDRADIUS, and CIRCUMRADIUS for $a = 1$ are

$$r = \tfrac{9}{872}(21 + \sqrt{5})\sqrt{58 + 18\sqrt{5}} \approx 2.37713$$
$$\rho = \tfrac{3}{4}(1 + \sqrt{5}) \approx 2.42705$$
$$R = \tfrac{1}{4}\sqrt{58 + 18\sqrt{5}} \approx 2.47802.$$

Truncated Icosidodecahedron

see GREAT RHOMBICOSIDODECAHEDRON (ARCHIMEDEAN)

Truncated Octahedral Number

A FIGURATE NUMBER which is constructed as an OCTAHEDRAL NUMBER with a SQUARE PYRAMID removed from each of the six VERTICES,

$$TO_n = O_{3n-2} - 6P_{n-1} = \tfrac{1}{3}(3n-2)[2(3n-2)^2 + 1],$$

where O_n is an OCTAHEDRAL NUMBER and P_n is a PYRAMIDAL NUMBER. The first few are 1, 38, 201, 586, ... (Sloane's A005910). The GENERATING FUNCTION for the truncated octahedral numbers is

$$\frac{x(6x^3 + 55x^2 + 34x + 1)}{(x-1)^4} = x + 38x^2 + 201x^3 + \ldots.$$

see also OCTAHEDRAL NUMBER

References

Conway, J. H. and Guy, R. K. *The Book of Numbers.* New York: Springer-Verlag, p. 52, 1996.

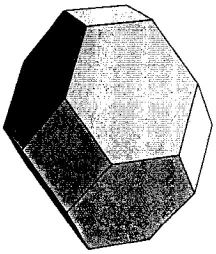
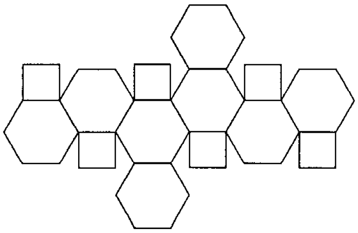
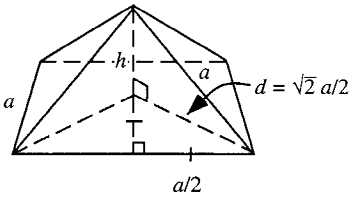
Truncated Octahedron





An ARCHIMEDEAN SOLID, also known as the MECON, whose DUAL POLYHEDRON is the TETRAKIS HEXAHEDRON. It is also UNIFORM POLYHEDRON U_8 and has SCHLÄFLI SYMBOL t{3, 4} and WYTHOFF SYMBOL 2 4 | 3. The faces of the truncated octahedron are 8{6}+6{4}. The truncated octahedron has the O_h OCTAHEDRAL GROUP of symmetries.



The solid can be formed from an OCTAHEDRON via TRUNCATION by removing six SQUARE PYRAMIDS, each with edge slant height $a = s/3$ and height h, where s is the side length of the original OCTAHEDRON. From the above diagram, the height and base area of the SQUARE PYRAMID are

$$h = \sqrt{a^2 - d^2} = \tfrac{1}{2}\sqrt{2}\,a \tag{1}$$

$$A_b = a^2. \tag{2}$$

The VOLUME of the truncated octahedron is then given by the VOLUME of the OCTAHEDRON

$$V_{\text{octahedron}} = \tfrac{1}{3}\sqrt{2}\,s^3 = 9\sqrt{2}\,a^3 \tag{3}$$

minus six times the volume of the SQUARE PYRAMID,

$$V = V_{\text{octahedron}} - 6(\tfrac{1}{3}A_b h) = (9\sqrt{2} - \sqrt{2})a^3 = 8\sqrt{2}\,a^3. \tag{4}$$

The truncated octahedron is a SPACE-FILLING POLYHEDRON. The INRADIUS, MIDRADIUS, and CIRCUMRADIUS for $a = 1$ are

$$r = \tfrac{9}{20}\sqrt{10} \approx 1.42302 \tag{5}$$

$$\rho = \tfrac{3}{2} = 1.5 \tag{6}$$

$$R = \tfrac{1}{2}\sqrt{10} \approx 1.58114. \tag{7}$$

Truncated Polyhedron

A polyhedron with truncated faces, given by the SCHLÄFLI SYMBOL $\mathrm{t}\left\{\begin{smallmatrix} p \\ q \end{smallmatrix}\right\}$.

see also RHOMBIC POLYHEDRON, SNUB POLYHEDRON

Truncated Pyramid

see PYRAMIDAL FRUSTUM

Truncated Square Pyramid

The truncated square pyramid is a special case of a PYRAMIDAL FRUSTUM for a SQUARE PYRAMID. Let the base and top side lengths of the truncated pyramid be a and b, and let the height be h. Then the VOLUME of the solid is

$$V = \tfrac{1}{3}(a^2 + ab + b^2)h.$$

This FORMULA was known to the Egyptians ca. 1850 BC. The Egyptians cannot have proved it without calculus, however, since Dehn showed in 1900 that no proof of this equation exists which does not rely on the concept of continuity (and therefore some form of INTEGRATION).

see also FRUSTUM, PYRAMID, PYRAMIDAL FRUSTUM, SQUARE PYRAMID

Truncated Tetrahedral Number

A FIGURATE NUMBER constructed by taking the $(3n-2)$th TETRAHEDRAL NUMBER and removing the $(n-1)$th TETRAHEDRAL NUMBER from each of the four corners,

$$\mathrm{Ttet}_n \equiv \mathrm{Te}_{3n-3} - 4\mathrm{Te}_{n-1} = \tfrac{1}{6}n(23n^2 - 27n + 10).$$

The first few are 1, 16, 68, 180, 375, ... (Sloane's A005906). The GENERATING FUNCTION for the truncated tetrahedral numbers is

$$\frac{x(10x^2 + 12x + 1)}{(x-1)^4} = x + 16x^2 + 89x^3 + 180x^4 + \ldots.$$

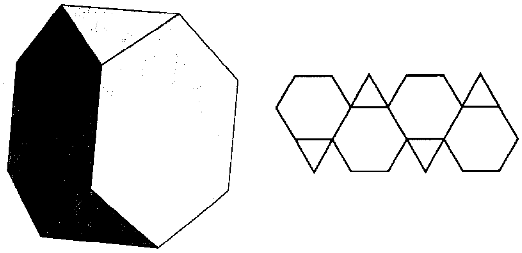
Truncated Tetrahedron



An ARCHIMEDEAN SOLID whose dual is the TRIAKIS TETRAHEDRON. It has SCHLÄFLI SYMBOL t{3,3}. It is also UNIFORM POLYHEDRON U_2 and has WYTHOFF SYMBOL 2 3 | 3. Its faces are 4{3} + 4{6}. The INRADIUS, MIDRADIUS, and CIRCUMRADIUS for a truncated tetrahedron with $a = 1$ are

$$\begin{aligned} r &= \tfrac{9}{44}\sqrt{22} \approx 0.95940 \\ \rho &= \tfrac{3}{4}\sqrt{2} \approx 1.06066 \\ R &= \tfrac{1}{4}\sqrt{22} \approx 1.17260. \end{aligned}$$

Truncation

The removal of portions of SOLIDS falling outside a set of symmetrically placed planes. The five PLATONIC SOLIDS belong to one of the following three truncation series (which, in the first two cases, carry the solid to its DUAL POLYHEDRON).

Truth Table

A truth table is a 2-D array with $n + 1$ columns. The first n columns correspond to the possible values of n inputs, and the last column to the operation being performed. The rows list all possible combinations of inputs together with the corresponding outputs. For example, the following truth table shows the result of the binary AND operator acting on two inputs A and B, each of which may be true or false.

A	B	$A \wedge B$
F	F	F
F	T	F
T	F	F
T	T	T

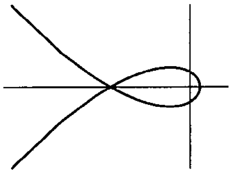
Tschirnhausen Cubic



The Tschirnhausen cubic is a plane curve given by

$$a = r\cos^3\left(\tfrac{1}{3}\theta\right),$$

and is also known as CATALAN'S TRISECTRIX and L'HOSPITAL'S CUBIC. The name Tschirnhaus's cubic is given in R. C. Archibald's 1900 paper attempting to classify curves (MacTutor Archive). Tschirnhaus's cubic is the NEGATIVE PEDAL CURVE of a PARABOLA with respect to the FOCUS.

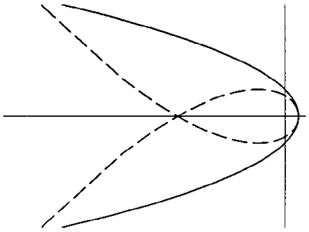
Tschirnhausen Cubic Pedal Curve



The PEDAL CURVE to the TSCHIRNHAUSEN CUBIC for PEDAL POINT at the origin is the PARABOLA

$$\begin{aligned} x &= 1 - t^2 \\ y &= 2t. \end{aligned}$$

see also PARABOLA, PEDAL CURVE, PEDAL POINT, TSCHIRNHAUSEN CUBIC

Tschirnhausen Transformation

A transformation of a POLYNOMIAL equation $f(x) = 0$ which is of the form $y = g(x)/h(x)$ where g and h are POLYNOMIALS and $h(x)$ does not vanish at a root of $f(x) = 0$. The CUBIC EQUATION is a special case of such a transformation. Tschirnhaus (1683) showed that a POLYNOMIAL of degree $n > 2$ can be reduced to a form in which the x^{n-1} and x^{n-2} terms have 0 COEFFICIENTS. In 1786, E. S. Bring showed that a general QUINTIC EQUATION can be reduced to the form

$$x^5 + px + q = 0.$$

In 1834, G. B. Jerrard showed that a Tschirnhaus transformation can be used to eliminate the x^{n-1}, x^{n-2}, *and* x^{n-3} terms for a general POLYNOMIAL equation of degree $n > 3$.

Tucker Circles

Let three equal lines P_1Q_1, P_2Q_2, and P_3Q_3 be drawn ANTIPARALLEL to the sides of a triangle so that two (say P_2Q_2 and P_3Q_3) are on the same side of the third line as $A_2P_2Q_3A_3$. Then $P_2Q_3P_3Q_2$ is an isosceles TRAPEZOID, i.e., P_3Q_2, P_1Q_3, and P_2Q_1 are parallel to the respective sides. The MIDPOINTS C_1, C_2, and C_3 of the antiparallels are on the respective symmedians and divide them proportionally.

If T divides KO in the same ratio, TC_1, TC_2, TC_3 are parallel to the radii OA_1, OA_2, and OA_3 and equal. Since the antiparallels are perpendicular to the symmedians, they are equal chords of a circle with center T which passes through the six given points. This circle is called the Tucker circle.

If

$$c \equiv \frac{\overline{KC_1}}{\overline{KA_1}} = \frac{\overline{KC_2}}{\overline{KA_2}} = \frac{\overline{KC_3}}{\overline{KA_3}} = \frac{\overline{KT}}{\overline{KO}},$$

then the radius of the Tucker circle is

$$R\sqrt{c^2 + (1-c)^2 \tan\omega},$$

where ω is the BROCARD ANGLE.

The COSINE CIRCLE, LEMOINE CIRCLE, and TAYLOR CIRCLE are Tucker circles.

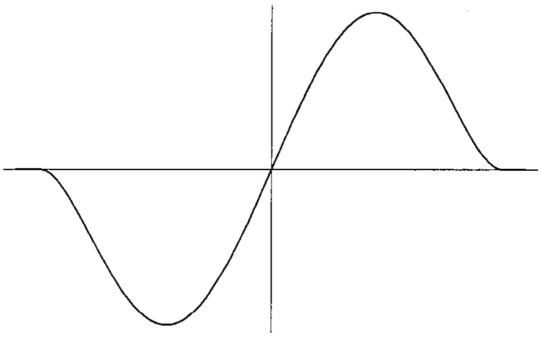
Tukey's Biweight



The function

$$\psi(z) = \begin{cases} z\left(1 - \frac{z^2}{c^2}\right)^2 & \text{for } |z| < c \\ 0 & \text{for } |z| > c \end{cases}$$

sometimes used in ROBUST ESTIMATION. It has a minimum at $z = -c/\sqrt{3}$ and a maximum at $z = c/\sqrt{3}$, where

$$\psi'(z) = 1 - \frac{3x^2}{c^2} = 0,$$

and an inflection point at $z = 0$, where

$$\psi''(z) = -\frac{6z}{c^2} = 0.$$

Turán Graph

The (n, k)-Turán graph is the EXTREMAL GRAPH on n VERTICES which contains no k-CLIQUE. In other words, the Turán graph has the maximum possible number of EDGES of any n-vertex graph not containing a COMPLETE GRAPH K_k. TURÁN'S THEOREM gives the maximum number of edges $t(n,k)$ for the (n,k)-Turán graph. For $k = 3$,

$$t(n,3) = \tfrac{1}{4}n^4,$$

so the Turán graph is given by the COMPLETE BIPARTITE GRAPHS

$$\begin{cases} K_{n/2,n/2} & n \text{ even} \\ K_{(n-1)/2,(n+1)/2} & n \text{ odd.} \end{cases}$$

Turbine

A VECTOR FIELD on a CIRCLE in which the directions of the VECTORS are all at the same ANGLE to the CIRCLE.

see also CIRCLE, VECTOR FIELD

Turing Machine

A theoretical computing machine which consists of an infinitely long magnetic tape on which instructions can be written and erased, a single-bit register of memory, and a processor capable of carrying out the following instructions: move the tape right, move the tape left, change the state of the register based on its current value and a value on the tape, and write or erase a value on the tape. The machine keeps processing instructions until it reaches a particular state, causing it to halt. Determining whether a Turing machine will halt for a given input and set of rules is called the HALTING PROBLEM.

Twin Peaks

For an Integer $n\geq 2$, let $\operatorname{lpf}(x)$ denote the Least Prime Factor of n. A Pair of Integers (x,y) is called a twin peak if

1. $x<y$,
2. $\operatorname{lpf}(x)=\operatorname{lpf}(y)$,
3. For all z, $x<z<y$ Implies $\operatorname{lpf}(z)<\operatorname{lpf}(x)$.

A broken-line graph of the least prime factor function resembles a jagged terrain of mountains. In terms of this terrain, a twin peak consists of two mountains of equal height with no mountain of equal or greater height between them. Denote the height of twin peak (x,y) by $p=\operatorname{lpf}(x)=\operatorname{lpf}(y)$. By definition of the Least Prime Factor function, p must be Prime.

Call the distance between two twin peaks (x,y)

$$s\equiv y-x.$$

Then s must be an Even multiple of p; that is, $s=kp$ where k is Even. A twin peak with $s=kp$ is called a kp-twin peak. Thus we can speak of $2p$-twin peaks, $4p$-twin peaks, etc. A kp-twin peak is fully specified by k, p, and x, from which we can easily compute $y\equiv x+kp$.

The set of kp-twin peaks is periodic with period $q=p\#$, where $p\#$ is the Primorial of p. That is, if (x,y) is a kp-twin peak, then so is $(x+q,y+q)$. A fundamental kp-twin peak is a twin peak having x in the fundamental period $[0,q)$. The set of fundamental kp-twin peaks is symmetric with respect to the fundamental period; that is, if (x,y) is a twin peak on $[0,q)$, then so is $(q-y,q-x)$.

The question of the Existence of twin peaks was first raised by David Wilson in the math-fun mailing list on Feb. 10, 1997. Wilson already had privately showed the Existence of twin peaks of height $p\leq 13$ to be unlikely, but was unable to rule them out altogether. Later that same day, John H. Conway, Johan de Jong, Derek Smith, and Manjul Bhargava collaborated to discover the first twin peak. Two hours at the blackboard revealed that $p=113$ admits the $2p$-twin peak

$$x=126972592296404970720882679404584182254788131,$$

which settled the Existence question. Immediately thereafter, Fred Helenius found the smaller $2p$-twin peak with $p=89$ and

$$x=9503844926749390990454854843625839.$$

The effort now shifted to finding the least Prime p admitting a $2p$-twin peak. On Feb. 12, 1997, Fred Helenius found $p=71$, which admits 240 fundamental $2p$-twin peaks, the least being

$$x=7310131732015251470110369.$$

Helenius's results were confirmed by Dan Hoey, who also computed the least $2p$-twin peak $L(2p)$ and number of fundamental $2p$-twin peaks $N(2p)$ for $p = 73$, 79, and 83. His results are summarized in the following table.

p	$L(2p)$	$N(2p)$
71	7310131732015251470110369	240
73	2061519317176132799110061	40296
79	3756800873017263196139951	164440
83	6316254452384500173544921	6625240

The $2p$-twin peak of height $p = 73$ is the smallest known twin peak. Wilson found the smallest known $4p$-twin peak with $p = 1327$, as well as another very large $4p$-twin peak with $p = 3203$. Richard Schroeppel noted that the latter twin peak is at the high end of its fundamental period and that its reflection within the fundamental period $[0, p\#)$ is smaller.

Many open questions remain concerning twin peaks, e.g.,

1. What is the smallest twin peak (smallest n)?
2. What is the least PRIME p admitting a $4p$-twin peak?
3. Do $6p$-twin peaks exist?
4. Is there, as Conway has argued, an upper bound on the span of twin peaks?
5. Let $p < q < r$ be PRIME. If p and r each admit kp-twin peaks, does q then necessarily admit a kp-twin peak?

see also ANDRICA'S CONJECTURE, DIVISOR FUNCTION, LEAST COMMON MULTIPLE, LEAST PRIME FACTOR

Twin Prime Conjecture

Adding a correction proportional to $1/\ln p$ to a computation of BRUN'S CONSTANT ending with $\ldots + 1/p + 1/(p+2)$ will give an estimate with error less than $c(\sqrt{p}\,\ln p)^{-1}$. An extended form of the conjecture states that

$$P_x(p, p+2) \sim 2\Pi_2 \int_2^x \frac{dx}{(\ln x)^2},$$

where Π_2 is the TWIN PRIMES CONSTANT. The twin prime conjecture is a special case of the more general PRIME PATTERNS CONJECTURE corresponding to the set $S = \{0, 2\}$.

see also BRUN'S CONSTANT, PRIME ARITHMETIC PROGRESSION, PRIME CONSTELLATION, PRIME PATTERNS CONJECTURE, TWIN PRIMES

Twin Primes

Twin primes are PRIMES (p, q) such that $p - q = 2$. The first few twin primes are $n \pm 1$ for $n = 4$, 6, 12, 18, 30, 42, 60, 72, 102, 108, 138, 150, 180, 192, 198, 228, 240, 270, 282, ... (Sloane's A014574). Explicitly, these are (3, 5), (5, 7), (11, 13), (17, 19), (29, 31), (41, 43), ... (Sloane's A001359 and A006512).

Let $\pi_2(n)$ be the number of twin primes p and $p+2$ such that $p \leq n$. It is not known if there are an infinite number of such PRIMES (Shanks 1993), but all twin primes except (3, 5) are of the form $6n \pm 1$. J. R. Chen has shown there exists an INFINITE number of PRIMES p such that $p + 2$ has at most two factors (Le Lionnais 1983, p. 49). Bruns proved that there exists a computable INTEGER x_0 such that if $x \geq x_0$, then

$$\pi_2(x) < \frac{100x}{(\ln x)^2} \tag{1}$$

(Ribenboim 1989, p. 201). It has been shown that

$$\pi_2(x) \leq c \prod_{p>2} \left[1 - \frac{1}{(p-1)^2}\right] \frac{x}{(\ln x)^2} \left[1 + \mathcal{O}\left(\frac{\ln \ln x}{\ln x}\right)\right], \tag{2}$$

where c has been reduced to $68/9 \approx 7.5556$ (Fouvry and Iwaniec 1983), $128/17 \approx 7.5294$ (Fouvry 1984), 7 (Bombieri *et al.* 1986), 6.9075 (Fouvry and Grupp 1986), and 6.8354 (Wu 1990). The bound on c is further reduced to 6.8324107886 in a forthcoming thesis by Haugland (1998). This calculation involved evaluation of 7-fold integrals and fitting of three different parameters. Hardy and Littlewood conjectured that $c = 2$ (Ribenboim 1989, p. 202).

Define

$$E \equiv \liminf_{n\to\infty} \frac{p_{n+1} - p_n}{\ln p_n}. \tag{3}$$

If there are an infinite number of twin primes, then $E = 0$. The best upper limit to date is $E \leq \frac{1}{4} + \pi/16 = 0.44634\ldots$ (Huxley 1973, 1977). The best previous values were 15/16 (Ricci), $(2 + \sqrt{3})/8 = 0.46650\ldots$ (Bombieri and Davenport 1966), and $(2\sqrt{2} - 1)/4 = 0.45706\ldots$ (Pil'Tai 1972), as quoted in Le Lionnais (1983, p. 26).

Some large twin primes are $10{,}006{,}428 \pm 1$, $1{,}706{,}595 \times 2^{11235} \pm 1$, and $571{,}305 \times 2^{7701} \pm 1$. An up-to-date table of known twin primes with 2000 or more digits follows. An extensive list is maintained by `Caldwell`.

$(p, p+1)$	dig.	Reference
$260{,}497{,}545 \times 2^{6625} \pm 1$	2003	Atkin & Rickert 1984

$1{,}692{,}923{,}232 \cdot 10^{4020} \pm 1$	4030	Dubner 1993
$6{,}797{,}727 \cdot 2^{15328} \pm 1$	4622	Forbes 1995
$697{,}053{,}813\dot{2}^{16352} \pm 1$	4932	Indlekofer & Ja'rai 1994
$570{,}918{,}348 \cdot 10^{5120} \pm 1$	5129	Dubner 1995
$242{,}206{,}083 \cdot 2^{38880} \pm 1$	11713	Indlekofer & Ja'rai 1995

The last of these is the largest known twin prime pair. In 1995, Nicely discovered a flaw in the Intel® Pentium™ microprocessor by computing the reciprocals of 824,633,702,441 and 824,633,702,443, which should have been accurate to 19 decimal places but were incorrect from the tenth decimal place on (Cipra 1995, 1996; Nicely 1996).

If $n \geq 2$, the INTEGERS n and $n+2$ form a pair of twin primes IFF

$$4[(n-1)!+1]+n \equiv 0 \pmod{n(n+2)}. \qquad (4)$$

$n = pp'$ where (p, p') is a pair of twin primes IFF

$$\phi(n)\sigma(n) = (n-3)(n+1) \qquad (5)$$

(Ribenboim 1989). The values of $\pi_2(n)$ were found by Brent (1976) up to $n = 10^{11}$. T. Nicely calculated them up to 10^{14} in his calculation of BRUN'S CONSTANT. The following table gives the number less than increasing powers of 10 (Sloane's A007508).

n	$\pi_2(n)$
10^3	35
10^4	205
10^5	1224
10^6	8,169
10^7	58,980
10^8	440,312
10^9	3,424,506
10^{10}	27,412,679
10^{11}	224,376,048
10^{12}	1,870,585,220
10^{13}	15,834,664,872
10^{14}	135,780,321,665

Twin Primes Constant

The twin primes constant Π_2 is defined by

$$\Pi_2 \equiv \prod_{\substack{p>2\\ p\text{ prime}}} \left[1 - \frac{1}{(p-1)^2}\right] \qquad (1)$$

$$\begin{aligned}\ln(\tfrac{1}{2}\Pi_2) &= \sum_{\substack{p\geq 3\\ p\text{ prime}}} \ln\left[\frac{p(p-2)}{(p-1)^2}\right]\\ &= \sum_{\substack{p\geq 3\\ p\text{ prime}}} \left[\ln\left(1-\frac{2}{p}\right) - 2\ln\left(1-\frac{1}{p}\right)\right]\\ &= -\sum_{j=2}^{\infty} \frac{2^j-2}{j} \sum_{\substack{p\geq 3\\ p\text{ prime}}} p^{-j}, \qquad (2)\end{aligned}$$

where the ps in sums and products are taken over PRIMES only. Flajolet and Vardi (1996) give series with accelerated convergence

$$\begin{aligned}\Pi_2 &= \prod_{n=2}^{\infty} [\zeta(n)(1-2^{-n})]^{-I_n} \qquad (3)\\ &= \tfrac{3}{4}\tfrac{15}{16}\tfrac{35}{36} \prod_{n=2}^{\infty} [\zeta(n)(1-2^{-n})(1-3^{-n})(1-5^{-n})\\ &\qquad \times(1-7^{-n})]^{-I_n}, \qquad (4)\end{aligned}$$

with

$$I_n \equiv \frac{1}{n}\sum_{d|n}\mu(d)2^{n/d}, \qquad (5)$$

where $\mu(x)$ is the MÖBIUS FUNCTION. (4) has convergence like $\sim (11/2)^{-n}$.

The most accurately known value of Π_2 is

$$\Pi_2 = 0.6601618158\ldots. \qquad (6)$$

Le Lionnais (1983, p. 30) calls C_2 the SHAH-WILSON CONSTANT, and $2C_2$ the twin prime constant (Le Lionnais 1983, p. 37).

Twins

see BROTHERS, PAIR

Twirl

A ROTATION combined with an EXPANSION or DILATION.

see also SCREW, SHIFT

Twist

The twist of a ribbon measures how much it twists around its axis and is defined as the integral of the incremental twist around the ribbon. Letting Lk be the linking number of the two components of a ribbon, Tw be the twist, and Wr be the WRITHE, then

$$\mathrm{Lk}(R) = \mathrm{Tw}(R) + \mathrm{Wr}(R)$$

(Adams 1994, p. 187).

Tychonof Compactness Theorem

The topological product of any number of COMPACT SPACES is COMPACT.

Type

Whitehead and Russell (1927) devised a hierarchy of "types" in order to eliminate self-referential statements from *Principia Mathematica*, which purported to derive all of mathematics from logic. A set of the lowest type contained only objects (not sets), a set of the next higher type could contain only objects or sets of the lower type, and so on. Unfortunately, GÖDEL'S INCOMPLETENESS THEOREM showed that both *Principia Mathematica* and all consistent formal systems must be incomplete.

Ulam Number

see ULAM SEQUENCE

Ulam's Problem

see COLLATZ PROBLEM

Ulam Sequence

The Ulam sequence $\{a_i\} = (u, v)$ is defined by $a_1 = u$, $a_2 = v$, with the general term a_n for $n > 2$ given by the least INTEGER expressible uniquely as the SUM of two distinct earlier terms. The numbers so produced are sometimes called U-NUMBERS or ULAM NUMBERS.

The first few numbers in the (1, 2) Ulam sequence are 1, 2, 3, 4, 6, 8, 11, 13, 16, ... (Sloane's A002858). Here, the first term after the initial 1, 2 is obviously 3 since $3 = 1 + 2$. The next term is $4 = 1 + 3$. (We don't have to worry about $4 = 2 + 2$ since it is a sum of a single term instead of *unique* terms.) 5 is not a member of the sequence since it is representable in *two* ways, $5 = 1 + 4 = 2 + 3$, but $6 = 2 + 4$ is a member. Proceeding in the manner, we can generate Ulam sequences for any (u, v), examples of which are given below.

$$\begin{aligned}
(1,2) &= \{1,2,3,4,6,8,11,13,16,18,\ldots\}\\
(1,3) &= \{1,3,4,5,6,8,10,12,17,21,\ldots\}\\
(1,4) &= \{1,4,5,6,7,8,10,16,18,19,\ldots\}\\
(1,5) &= \{1,5,6,7,8,9,10,12,20,22,\ldots\}\\
(2,3) &= \{2,3,5,7,8,9,13,14,18,19,\ldots\}\\
(2,4) &= \{2,4,6,8,12,16,22,26,32,36,\ldots\}\\
(2,5) &= \{2,5,7,9,11,12,13,15,19,23,\ldots\}.
\end{aligned}$$

Schmerl and Spiegel (1994) proved that Ulam sequences $(2, v)$ for ODD $v \geq 5$ have exactly two EVEN terms. Ulam sequences with only finitely many EVEN terms eventually must have periodic successive differences (Finch 1991, 1992abc). Cassaigne and Finch (1995) proved that the Ulam sequences $(4, v)$ for $5 \leq v \equiv 1 \pmod 4$ have exactly three EVEN terms.

The Ulam sequence can be generalized by the s-ADDITIVE SEQUENCE.

Ultrametric

An ultrametric is a METRIC which satisfies the following strengthened version of the TRIANGLE INEQUALITY,

$$d(x,z) \leq \max(d(x,y), d(y,z))$$

for all x, y, z. At least two of $d(x,y)$, $d(y,z)$, and $d(x,z)$ are the same.

Let X be a Set, and let $X^{\mathbb{N}}$ (where $\mathbb{N}$ is the Set of Natural Numbers) denote the collection of sequences of elements of X (i.e., all the possible sequences x_1, x_2, x_3, …). For sequences $a = (a_1, a_2, \ldots)$, $b = (b_1, b_2, \ldots)$, let n be the number of initial places where the sequences agree, i.e., $a_1 = b_1$, $a_2 = b_2$, …, $a_n = b_n$, but $a_{n+1} \neq b_{n+1}$. Take $n = 0$ if $a_1 \neq b_1$. Then defining $d(a,b) = 2^{-n}$ gives an ultrametric.

The p-adic Number metric is another example of an ultrametric.

see also Metric, p-adic Number

Ultraradical

A symbol which can be used to express solutions not obtainable by finite Root extraction. The solution to the irreducible Quintic Equation

$$x^5 + x = a$$

is written $\smallint\!\overline{a}$.

see also Radical

Ultraspherical Differential Equation

$$(1-x^2)y'' - (2\alpha+1)xy' + n(n+2\alpha)y = 0. \quad (1)$$

Alternate forms are

$$(1-x^2)Y'' + (2\lambda-3)xY' + (n+1)(n+2\lambda-1)Y = 0, \quad (2)$$

where

$$Y = (1-x^2)^{\lambda-1/2} P_n^{(\lambda)}(x), \quad (3)$$

$$\frac{d^2u}{dx^2} + \left[\frac{(n+\lambda)^2}{1-x^2} + \frac{\frac{1}{2} + \lambda - \lambda^2 + \frac{1}{4}x^2}{(1-x^2)^2}\right] u = 0, \quad (4)$$

where

$$u = (1-x^2)^{\lambda/2+1/4} P_n^{(\lambda)}(x), \quad (5)$$

and

$$\frac{d^2u}{d\theta^2} + \left[(n+\lambda)^2 + \frac{\lambda(1-\lambda)}{\sin^2\theta}\right] u = 0, \quad (6)$$

where

$$u = \sin^\lambda \theta \, P_n^{(\lambda)}(\cos\theta). \quad (7)$$

The solutions are the Ultraspherical Functions $P_n^{(\lambda)}(x)$. For integral n with $\alpha < 1/2$, the function converges to the Ultraspherical Polynomials $C_n^{(\alpha)}(x)$.

References

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I.* New York: McGraw-Hill, pp. 547–549, 1953.

Ultraspherical Function

A function defined by a Power Series whose coefficients satisfy the Recurrence Relation

$$a_{j+2} = a_j \frac{(k+j)(k+j+2\alpha) - n(n+2\alpha)}{(k+j+1)(k+j+2)}.$$

For $x \neq -1$, the function converges for $\alpha < 1/2$ and diverges for $\alpha > 1/2$.

Ultraspherical Polynomial

The ultraspherical polynomials are solutions $P_n^{(\lambda)}(x)$ to the Ultraspherical Differential Equation for Integer n and $\alpha < 1/2$. They are generalizations of Legendre Polynomials to $(n+2)$-D space and are proportional to (or, depending on the normalization, equal to) the Gegenbauer Polynomials $C_n^{(\lambda)}(x)$, denoted in *Mathematica*® (Wolfram Research, Champaign, IL) `GegenbauerC[n,lambda,x]`. The ultraspherical polynomials are also Jacobi Polynomials with $\alpha = \beta$. They are given by the Generating Function

$$\frac{1}{(1-2xt+t^2)^\lambda} = \sum_{n=0}^{\infty} P_n^{(\lambda)}(x) t^n, \quad (1)$$

and can be given explicitly by

$$P_n^{(\lambda)}(x) = \frac{\Gamma(\lambda+\frac{1}{2})}{\Gamma(2\lambda)} \frac{\Gamma(n+2\lambda)}{\Gamma(n+\lambda+\frac{1}{2})} P_n^{(\lambda-1/2,\lambda-1/2)}(x), \quad (2)$$

where $P_n^{(\lambda-1/2,\lambda-1/2)}$ is a Jacobi Polynomial (Szegő 1975, p. 80). The first few ultraspherical polynomials are

$$P_0^{(\lambda)}(x) = 1 \quad (3)$$

$$P_1^{(\lambda)}(x) = 2\lambda x \quad (4)$$

$$P_2^{(\lambda)}(x) = -\lambda + 2\lambda(1+\lambda)x^2 \quad (5)$$

$$P_3^{(\lambda)}(x) = -2\lambda(1+\lambda)x + \tfrac{4}{3}\lambda(1+\lambda)(2+\lambda)x^3. \quad (6)$$

In terms of the Hypergeometric Functions,

$$P_n^{(\lambda)}(x) = \binom{n+2\lambda-1}{n} \times {}_2F_1(-n, n+2\lambda; \lambda+\tfrac{1}{2}; \tfrac{1}{2}(1-x)) \quad (7)$$

$$= 2^n \binom{n+\lambda-1}{n} (x-1)^n \times {}_2F_1\left(-n, -n-\lambda+\tfrac{1}{2}; -2n-2\lambda+1; \frac{2}{1-x}\right) \quad (8)$$

$$= \binom{n+2\lambda+1}{n} \left(\frac{x+1}{2}\right)^n \times {}_2F_1\left(-n, -n-\lambda+\tfrac{1}{2}; \lambda+\tfrac{1}{2}; \frac{x-1}{x+1}\right). \quad (9)$$

They are normalized by

$$\int_{-1}^{1}(1-x^2)^{\lambda-1/2}[P_n^{(\lambda)}]^2\,dx = 2^{1-2\lambda}\pi\frac{\Gamma(n+2\lambda)}{(n+\lambda)\Gamma^2(\lambda)\Gamma(n+1)}. \tag{10}$$

Derivative identities include

$$\frac{d}{dx}P_n^{(\lambda)}(x) = 2\lambda P_{n-1}^{(\lambda+1)}(x) \tag{11}$$

$$(1-x^2)\frac{d}{dx}[P_n^{(\lambda)}] = [2(n+\lambda)]^{-1}[(n+2\lambda-1) \times(n+2\lambda)P_{n-1}^{(\lambda)}(x) - n(n+1)P_{n+1}^{(\lambda)}(x)] \tag{12}$$

$$= -nxP_n^{(\lambda)}(x) + (n+2\lambda-1)P_{n-1}^{(\lambda)}(x) \tag{13}$$

$$= (n+2\lambda)xP_n^{(\lambda)}(x) - (n+1)P_{n+1}^{(\lambda)}(x) \tag{14}$$

$$nP_n^{(\lambda)}(x) = x\frac{d}{dx}[P_n^{(\lambda)}(x)] - \frac{d}{dx}[P_{n-1}^{(\lambda)}(x)] \tag{15}$$

$$(n+2\lambda)P_n^{(\lambda)}(x) = \frac{d}{dx}[P_{n+1}^{(\lambda)}(x)] - x\frac{d}{dx}[P_n^{(\lambda)}(x)] \tag{16}$$

$$\frac{d}{dx}[P_{n+1}^{(\lambda)}(x) - P_{n-1}^{(\lambda)}(x)] = 2(n+\lambda)P_n^{(\lambda)}P_n^{(\lambda)}(x) \tag{17}$$

$$= 2\lambda[P_n^{(\lambda+1)}(x) - P_{n-2}^{(\lambda+1)}(x)] \tag{18}$$

(Szegő 1975, pp. 80–83).

A Recurrence Relation is

$$nP_n^{(\lambda)}(x) = 2(n+\lambda-1)xP_{n-1}^{(\lambda)}(x) - (n+2\lambda-2)P_{n-2}^{(\lambda)}(x) \tag{19}$$

for $n = 2, 3, \ldots$.

Special double-ν Formulas also exist

$$P_{2\nu}^{(\lambda)}(x) = \binom{2\nu+2\lambda-1}{2\nu}{}_2F_1(-\nu,\nu+\lambda;\lambda+\tfrac{1}{2};1-x^2) \tag{20}$$

$$= (-1)^\nu\binom{\nu+\lambda-1}{\nu}{}_2F_1(-\nu,\nu+\lambda;\tfrac{1}{2};x^2) \tag{21}$$

$$P_{2\nu+1}^{(\lambda)}(x) = \binom{2\nu+2\lambda}{2\nu+1}x\,{}_2F_1(-\nu,\nu+\lambda+1;\lambda+\tfrac{1}{2};1-x^2) \tag{22}$$

$$= (-1)^\nu 2\lambda\binom{\nu+\lambda}{\nu}x\,{}_2F_1(-\nu,\nu+\lambda+1;\tfrac{3}{2};x^2). \tag{23}$$

Special values are given in the following table.

λ	Special Polynomial
$\frac{1}{2}$	Legendre
1	Chebyshev polynomial of the second kind

Koschmieder (1920) gives representations in terms of Elliptic Functions for $\alpha = -3/4$ and $\alpha = -2/3$.

Umbilic Point

A point on a surface at which the Curvature is the same in any direction.

Umbral Calculus

The study of certain properties of Finite Differences. The term was coined by Sylvester from the word "umbra" (meaning "shadow" in Latin), and reflects the fact that for many types of identities involving sequences of polynomials with Powers a^n, "shadow" identities are obtained when the polynomials are changed to discrete values and the exponent in a^n is changed to the Pochhammer Symbol $(a)_n \equiv a(a-1)\cdots(a-n+1)$.

For example, Newton's Forward Difference Formula written in the form

$$f(x+a) = \sum_{n=0}^{\infty}\frac{(a)_n\Delta^n f(x)}{n!} \tag{1}$$

with $f(x+a) \equiv f_{x+a}$ looks suspiciously like a finite analog of the Taylor Series expansion

$$f(x+a) = \sum_{n=0}^{\infty}\frac{a^n\tilde{D}^n f(x)}{n!}, \tag{2}$$

where $\tilde{D}$ is the Differential Operator. Similarly, the Chu-Vandermonde Identity

$$(x+a)_n = \sum_{k=0}^{\infty}\binom{n}{k}(a)_k(x)_{n-k} \tag{3}$$

with $\binom{n}{k}$ a Binomial Coefficient, looks suspiciously like an analog of the Binomial Theorem

$$(x+a)^n = \sum_{k=0}^{\infty}\binom{n}{k}a^k x^{n-k} \tag{4}$$

(Di Bucchianico and Loeb).

Umbrella

see WHITNEY UMBRELLA

Unambiguous

see WELL-DEFINED

Unbiased

A quantity which does not exhibit BIAS. An ESTIMATOR $\hat{\theta}$ is an UNBIASED ESTIMATOR of θ if

$$\langle\hat{\theta}\rangle = \theta.$$

see also BIAS (ESTIMATOR), ESTIMATOR

Uncia

$$1 \text{ uncia} \equiv \tfrac{1}{12}.$$

The word *uncia* was Latin for a unit equal to 1/12 of another unit called the *as*. The words "inch" (1/12 of a foot) and "ounce" (originally 1/12 of a pound and still 1/12 of a "Troy pound," now used primarily to weigh precious metals) are derived from the word *uncia*.

Uncorrelated

Variables x_i and x_j are said to be uncorrelated if their COVARIANCE is zero:

$$\operatorname{cov}(x_i, x_j) = 0.$$

INDEPENDENT STATISTICS are always uncorrelated, but the converse is not necessarily true.

see also COVARIANCE, INDEPENDENT STATISTICS

Uncountable Set

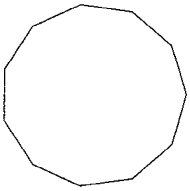
see UNCOUNTABLY INFINITE SET

Uncountably Infinite Set

An INFINITE SET which is not a COUNTABLY INFINITE SET.

see also ALEPH-0, ALEPH-1, COUNTABLE SET, COUNTABLY INFINITE SET, FINITE, INFINITE

Undecagon



The unconstructible 11-sided POLYGON with SCHLÄFLI SYMBOL $\{11\}$.

see also DECAGON, DODECAGON, TRIGONOMETRY VALUES—$\pi/11$

Undecidable

Not DECIDABLE as a result of being neither formally provable nor unprovable.

see also GÖDEL'S INCOMPLETENESS THEOREM, RICHARDSON'S THEOREM

Undecillion

In the American system, 10^{36}.

see also LARGE NUMBER

Undetermined Coefficients Method

Given a nonhomogeneous ORDINARY DIFFERENTIAL EQUATION, select a differential operator which will annihilate the right side, and apply it to both sides. Find the solution to the homogeneous equation, plug it into the left side of the original equation, and solve for constants by setting it equal to the right side. The solution is then obtained by plugging the determined constants into the homogeneous equation.

see also ORDINARY DIFFERENTIAL EQUATION

Undulating Number

A number of the form $aba\cdots$, $abab\cdots$, etc. The first few nontrivial undulants (with the stipulation that $a \neq b$) are 101, 121, 131, 141, 151, 161, 171, 181, 191, 202, 212, ... (Sloane's A046075). Including the trivial 1- and 2-digit undulants and dropping the requirement that $a \neq b$ gives Sloane's A033619.

The first few undulating SQUARES are 121, 484, 676, 69696, ... (Sloane's A016073), with no larger such numbers of fewer than a million digits (Pickover 1995). Several tricks can be used to speed the search for square undulating numbers, especially by examining the possible patterns of ending digits. For example, the only possible sets of four trailing digits for undulating SQUARES are 0404, 1616, 2121, 2929, 3636, 6161, 6464, 6969, 8484, and 9696.

The only undulating POWER $n^p = aba\cdots$ for $3 \leq p \leq 31$ and up to 100 digits is $7^3 = 343$ (Pickover 1995). A large undulating prime is given by $7 + 720(100^{49} - 1)/99$ (Pickover 1995).

A binary undulant is a POWER of 2 whose base-10 representation contains one or both of the sequences $010\cdots$ and $101\cdots$. The first few are 2^n for $n = 103$, 107, 138, 159, 179, 187, 192, 199, 205, ... (Sloane's A046076). The smallest n for which an undulating sequence of *exactly d*-digit occurs for $d = 3$, 4, ... are $n = 103$, 138, 875, 949, 6617, 1802, 14545, ... (Sloane's A046077). An undulating binary sequence of length 10 occurs for $n = 1,748,219$ (Pickover 1995).

Unduloid

A SURFACE OF REVOLUTION with constant NONZERO MEAN CURVATURE also called an ONDULOID. It is a ROULETTE obtained from the path described by the FOCI of a CONIC SECTION when rolled on a LINE. This curve then generates an unduloid when revolved about the LINE. These curves are special cases of the shapes assumed by soap film spanning the gap between prescribed boundaries. The unduloid of a PARABOLA gives a CATENOID.

Unexpected Hanging Paradox

A PARADOX also known as the SURPRISE EXAMINATION PARADOX or PREDICTION PARADOX.

A prisoner is told that he will be hanged on some day between Monday and Friday, but that he will not know on which day the hanging will occur before it happens. He cannot be hanged on Friday, because if he were still alive on Thursday, he would know that the hanging will occur on Friday, but he has been told he will not know the day of his hanging in advance. He cannot be hanged Thursday for the same reason, and the same argument shows that he cannot be hanged on any other day. Nevertheless, the executioner unexpectedly arrives on some day other than Friday, surprising the prisoner.

This PARADOX is similar to that in Robert Louis Stevenson's "The Imp in the Bottle," in which you are offered the opportunity to buy, for whatever price you wish, a bottle containing a genie who will fulfill your every desire. The only catch is that the bottle must thereafter be resold for a price smaller than what you paid for it, or you will be condemned to live out the rest of your days in excrutiating torment. Obviously, no one would buy the bottle for 1¢ since he would have to give the bottle away, but no one would accept the bottle knowing he would be unable to get rid of it. Similarly, no one would buy it for 2¢, and so on. However, for some reasonably large amount, it will always be possible to find a next buyer, so the bottle will be bought (Paulos 1995).

Unfinished Game

see SHARING PROBLEM

Unhappy Number

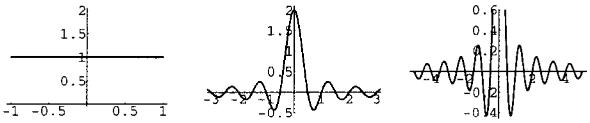
A number which is not HAPPY is said to be unhappy.

see also HAPPY NUMBER

Unicursal Circuit

A CIRCUIT in which an entire GRAPH is traversed in one route. An example of a curve which can be traced unicursally is the MOHAMMED SIGN.

Uniform Apodization Function



An APODIZATION FUNCTION

$$f(x) = 1, \tag{1}$$

having INSTRUMENT FUNCTION

$$I(x) = \int_{-a}^{a} e^{-2\pi ikx}\,dx = -\frac{1}{2\pi ik}(e^{-2\pi ika} - e^{2\pi ikx})$$
$$= \frac{\sin(2\pi ka)}{\pi k} = 2a\,\mathrm{sinc}(2\pi ka). \qquad (2)$$

The peak (in units of a) is 2. The extrema are given by letting $\beta \equiv 2\pi ka$ and solving

$$\frac{d}{d\beta}(\beta\sin\beta) = \frac{\sin\beta - \beta\cos\beta}{\beta^2} = 0 \qquad (3)$$

$$\sin\beta - \beta\cos\beta = 0 \qquad (4)$$

$$\tan\beta = \beta. \qquad (5)$$

Solving this numerically gives $\beta_0 = 0$, $\beta_1 = 4.49341$, $\beta_2 = 7.72525$, ... for the first few solutions. The second of these is the peak POSITIVE sidelobe, and the third is the peak NEGATIVE sidelobe. As a fraction of the peak, they are 0.128375 and −0.217234. The FULL WIDTH AT HALF MAXIMUM is found by setting $I(x) = 1$

$$\mathrm{sinc}(x) = \tfrac{1}{2}, \qquad (6)$$

and solving for $x_{1/2}$, yielding

$$x_{1/2} = 2\pi k_{1/2}a = 1.89549. \qquad (7)$$

Therefore, with $L \equiv 2a$,

$$\mathrm{FWHM} = 2k_{1/2} = \frac{0.603353}{a} = \frac{1.20671}{L}. \qquad (8)$$

see also APODIZATION FUNCTION

Uniform Boundedness Principle

If a "pointwise-bounded" family of continuous linear OPERATORS from a BANACH SPACE to a NORMED SPACE is "uniformly bounded." Symbolically, if $\sup ||T_i(x)||$ is FINITE for each x in the unit BALL, then $\sup ||T_i||$ is FINITE. The theorem is also called the BANACH-STEINHAUS THEOREM.

Uniform Convergence

A SERIES $\sum_{n=1}^{\infty} u_n(x)$ is uniformly convergent to $S(x)$ for a set E of values of x if, for each $\epsilon > 0$, an INTEGER N can be found such that

$$|S_n(x) - S(x)| < \epsilon \qquad (1)$$

for $n \geq N$ and all $x \in E$. To test for uniform convergence, use ABEL'S UNIFORM CONVERGENCE TEST or the WEIERSTRAß M-TEST. If individual terms $u_n(x)$ of a uniformly converging series are continuous, then

1. The series sum

$$f(x) = \sum_{n=1}^{\infty} u_n(x) \qquad (2)$$

is continuous,

2. The series may be integrated term by term

$$\int_a^b f(x)\,dx = \sum_{n=1}^{\infty}\int_a^b u_n(x)\,dx, \qquad (3)$$

and

3. The series may be differentiated term by term

$$\frac{d}{dx}f(x) = \sum_{n=1}^{\infty} n\frac{d}{dx}u_n(x). \qquad (4)$$

see also ABEL'S THEOREM, ABEL'S UNIFORM CONVERGENCE TEST, WEIERSTRAß M-TEST

References

Arfken, G. *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 299–301, 1985.

Uniform Distribution

A distribution which has constant probability is called a uniform distribution, sometimes also called a RECTANGULAR DISTRIBUTION. The probability density function and cumulative distribution function for a *continuous* uniform distribution are

$$P(x) = \begin{cases} \frac{1}{b-a} & \text{for } a < x < b \\ 0 & \text{for } x < a,\ x > b \end{cases} \qquad (1)$$

$$D(x) = \begin{cases} 0 & \text{for } x < a \\ \frac{x-a}{b-a} & \text{for } a \leq x < b \\ 1 & \text{for } x \geq b. \end{cases} \qquad (2)$$

With $a = 0$ and $b = 1$, these can be written

$$P(x) = \tfrac{1}{2}\,\mathrm{sgn}(x) - \mathrm{sgn}(x-1) \qquad (3)$$
$$D(x) = \tfrac{1}{2}[1 - (1-x)^2\,\mathrm{sgn}(1-x) + x\,\mathrm{sgn}(x)]. \qquad (4)$$

The CHARACTERISTIC FUNCTION is

$$\phi(t) = \frac{2}{ht}\sin(\tfrac{1}{2}ht)e^{imt}, \qquad (5)$$

where

$$a = m - \tfrac{1}{2}h \qquad (6)$$
$$b = m + \tfrac{1}{2}h. \qquad (7)$$

The MOMENT-GENERATING FUNCTION is

$$M(t) = \langle e^{xt}\rangle = \int_a^b \frac{e^{xt}}{b-a}dx = \left[\frac{e^{xt}}{t(b-a)}\right]_a^b, \qquad (8)$$

so

$$M(t) = \begin{cases} \frac{e^{tb}-e^{ta}}{t(b-a)} & \text{for } t \neq 0 \\ 0 & \text{for } t = 0, \end{cases} \tag{9}$$

and

$$\begin{aligned} M'(t) &= \frac{1}{b-a}\left[\frac{1}{t}(be^{bt} - ae^{at}) - \frac{1}{t^2}(e^{bt} - e^{at})\right] \\ &= \frac{e^{bt}(bt-1) - e^{at}(at-1)}{(b-a)t^2}. \end{aligned} \tag{10}$$

The function is not differentiable at zero, so the MOMENTS cannot be found using the standard technique. They can, however, be found by direct integration. The MOMENTS about 0 are

$$\mu'_1 = \tfrac{1}{2}(a+b) \tag{11}$$
$$\mu'_2 = \tfrac{1}{3}(a^2 + ab + b^2) \tag{12}$$
$$\mu'_3 = \tfrac{1}{4}(a+b)(a^2+b^2) \tag{13}$$
$$\mu'_4 = \tfrac{1}{5}(a^4 + a^3b + a^2b^2 + ab^3 + b^4). \tag{14}$$

The MOMENTS about the MEAN are

$$\mu_1 = 0 \tag{15}$$
$$\mu_2 = \tfrac{1}{12}(b-a)^2 \tag{16}$$
$$\mu_3 = 0 \tag{17}$$
$$\mu_4 = \tfrac{1}{80}(b-a)^4, \tag{18}$$

so the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \tfrac{1}{2}(a+b) \tag{19}$$
$$\sigma^2 = \mu_2 = \tfrac{1}{12}(b-a)^2 \tag{20}$$
$$\gamma_1 = \frac{\mu_3}{\sigma^{3/2}} = 0 \tag{21}$$
$$\gamma_2 = -\tfrac{6}{5}. \tag{22}$$

The probability distribution function and cumulative distributions function for a *discrete* uniform distribution are

$$P(n) = \frac{1}{N} \tag{23}$$
$$D(n) = \frac{n}{N} \tag{24}$$

for $n = 1, \ldots, N$. The MOMENT-GENERATING FUNCTION is

$$\begin{aligned} M(t) = \langle e^{nt} \rangle &= \sum_{n=1}^{N} \frac{1}{N} e^{nt} = \frac{1}{N}\frac{e^t - e^{t(N+1)}}{1-e^t} \\ &= \frac{e^t(1-e^{Nt})}{N(1-e^t)}. \end{aligned} \tag{25}$$

The MOMENTS about 0 are

$$\mu'_m = \frac{1}{N}\sum_{n=1}^{N} n^m, \tag{26}$$

so

$$\mu'_1 = \tfrac{1}{2}(N+1) \tag{27}$$
$$\mu'_2 = \tfrac{1}{6}(N+1)(2N+1) \tag{28}$$
$$\mu'_3 = \tfrac{1}{4}N(N+1)^2 \tag{29}$$
$$\mu'_4 = \tfrac{1}{30}(N+1)(2N+1)(3N^2+3N-1), \tag{30}$$

and the MOMENTS about the MEAN are

$$\mu_2 = \tfrac{1}{12}(N-1)(N+1) \tag{31}$$
$$\mu_3 = 0 \tag{32}$$
$$\mu_4 = \tfrac{1}{240}(N-1)(N+1)(3N^2-7). \tag{33}$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \tfrac{1}{2}(N+1) \tag{34}$$
$$\sigma^2 = \mu_2 = \tfrac{1}{12}(N-1)(N+1) \tag{35}$$
$$\gamma_1 = \frac{\mu_3}{\sigma^{3/2}} = 0 \tag{36}$$
$$\gamma_2 = \frac{6(N^2+1)}{5(N-1)(N+1)}. \tag{37}$$

Uniform Polyhedron

The uniform polyhedra are POLYHEDRA with identical VERTICES. Coxeter *et al.* (1954) conjectured that there are 75 such polyhedra in which only two faces are allowed to meet at an EDGE, and this was subsequently proven. (However, when any EVEN number of faces may meet, there are 76 polyhedra.) If the five pentagonal PRISMS are included, the number rises to 80.

The VERTICES of a uniform polyhedron all lie on a SPHERE whose center is their CENTROID. The VERTICES joined to another VERTEX lie on a CIRCLE.

Source code and binary programs for generating and viewing the uniform polyhedra are also available at `http://www.math.technion.ac.il/~rl/kaleido/`. The following depictions of the polyhedra were produced by R. Maeder's `UniformPolyhedra.m` package for *Mathematica*® (Wolfram Research, Champaign, IL). Due to a limitation in *Mathematica*'s renderer, uniform polyhedra 69, 72, 74, and 75 cannot be displayed using this package.

Uniform Variate

A RANDOM NUMBER which lies within a specified range (which can, without loss of generality, be taken as [0, 1]), with a UNIFORM DISTRIBUTION.

References

Press, W. H.; Flannery, B. P.; Teukolsky, S. A.; and Vetterling, W. T. "Uniform Deviates." §7.1 in *Numerical Recipes in FORTRAN: The Art of Scientific Computing, 2nd ed.* Cambridge, England: Cambridge University Press, pp. 267–277, 1992.

Unimodal Distribution

A DISTRIBUTION such as the GAUSSIAN DISTRIBUTION which has a single "peak."

see also BIMODAL DISTRIBUTION

Unimodal Sequence

A finite SEQUENCE which first increases and then decreases. A SEQUENCE $\{s_1, s_2, \ldots, s_n\}$ is unimodal if there exists a t such that

$$s_1 \leq s_2 \leq \ldots \leq s_t$$

and

$$s_t \geq s_{t+1} \geq \ldots \geq s_n.$$

Unimodular Group

A group whose left HAAR MEASURE equals its right HAAR MEASURE.

see also HAAR MEASURE

References

Knapp, A. W. "Group Representations and Harmonic Analysis, Part II." *Not. Amer. Math. Soc.* **43**, 537–549, 1996.

Unimodular Matrix

A MATRIX A with INTEGER elements and DETERMINANT $\det(\mathsf{A}) = \pm 1$, also called a UNIT MATRIX.

The inverse of a unimodular matrix is another unimodular matrix. A POSITIVE unimodular matrix has $\det(\mathsf{A}) = +1$. The nth POWER of a POSITIVE UNIMODULAR MATRIX

$$\mathsf{M} \equiv \begin{bmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{bmatrix} \tag{1}$$

is

$$\mathsf{M}^n = \begin{bmatrix} m_{11}U_{n-1}(a) - U_{n-2}(a) & m_{12}U_{n-1}(a) \\ m_{21}U_{n-1}(a) & m_{22}U_{n-1}(a) - U_{n-2}(a) \end{bmatrix}, \tag{2}$$

where

$$a \equiv \tfrac{1}{2}(m_{11} + m_{22}) \tag{3}$$

and the U_n are CHEBYSHEV POLYNOMIALS OF THE SECOND KIND,

$$U_m(x) = \frac{\sin[(m+1)\cos^{-1} x]}{\sqrt{1-x^2}}. \tag{4}$$

see also CHEBYSHEV POLYNOMIAL OF THE SECOND KIND

Unimodular Transformation

A transformation $\mathbf{x}' = \mathsf{A}\mathbf{x}$ is unimodular if the DETERMINANT of the MATRIX A satisfies

$$\det(\mathsf{A}) = \pm 1.$$

A NECESSARY and SUFFICIENT condition that a linear transformation transform a lattice to itself is that the transformation be unimodular.

Union

The union of two sets A and B is the set obtained by combining the members of each. This is written $A \cup B$, and is pronounced "A union B" or "A cup B." The union of sets A_1 through A_n is written $\bigcup_{i=1}^n A_i$.

Let A, B, C, ... be sets, and let $P(S)$ denote the probability of S. Then

$$P(A \cup B) = P(A) + P(B) - P(A \cap B). \tag{1}$$

Similarly,

$$\begin{aligned} &P(A \cup B \cup C) = P[A \cup (B \cup C)] \\ &= P(A) + P(B \cup C) - P[A \cap (B \cup C)] \\ &= P(A) + [P(B) + P(C) - P(B \cap C)] \\ &\quad -P[(A \cap B) \cup (A \cap C)] \\ &= P(A) + P(B) + P(C) - P(B \cap C) \\ &\quad -\{P(A \cap B) + P(A \cap C) - P[(A \cap B) \cap (A \cap C)]\} \\ &= P(A) + P(B) + P(C) - P(A \cap B) \\ &\quad -P(A \cap C) - P(B \cap C) + P(A \cap B \cap C). \end{aligned} \tag{2}$$

If A and B are DISJOINT, by definition $P(A \cap B) = 0$, so

$$P(A \cup B) = P(A) + P(B). \tag{3}$$

Continuing, for a set of n disjoint elements E_1, E_2, ..., E_n

$$P\left(\bigcup_{i=1}^{n} E_i\right) = \sum_{i=1}^{n} P(E_i), \tag{4}$$

which is the COUNTABLE ADDITIVITY PROBABILITY AXIOM. Now let

$$E_i \equiv A \cap B_i, \tag{5}$$

then

$$P\left(\bigcup_{i=1}^{n} E \cap B_i\right) = \sum_{i=1}^{n} P(E \cap B_i). \tag{6}$$

Uniplanar Double Point

see ISOLATED SINGULARITY

Unipotent

A p-ELEMENT x of a GROUP G is unipotent if $F^*(C_G(x))$ is a p-GROUP, where F^* is the generalized FITTING SUBGROUP.

see also FITTING SUBGROUP, p-ELEMENT, p-GROUP

Unique

The property of being the only possible solution (perhaps modulo a constant, class of transformation, etc.).

see also ALEKSANDROV'S UNIQUENESS THEOREM, EXISTENCE, MAY-THOMASON UNIQUENESS THEOREM

Unique Factorization Theorem

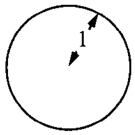
see FUNDAMENTAL THEOREM OF ARITHMETIC

Unit

A unit is an element in a RING that has a multiplicative inverse. If n is an ALGEBRAIC INTEGER which divides every ALGEBRAIC INTEGER in the FIELD, n is called a unit in that FIELD. A given FIELD may contain an infinity of units. The units of $\mathbb{Z}_n$ are the elements RELATIVELY PRIME to n. The units in $\mathbb{Z}_n$ which are SQUARES are called QUADRATIC RESIDUES.

see also EISENSTEIN UNIT, FUNDAMENTAL UNIT, PRIME UNIT, QUADRATIC RESIDUE

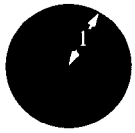
Unit Circle



A CIRCLE of RADIUS 1, such as the one used to defined the functions of TRIGONOMETRY.

see also UNIT DISK, UNIT SQUARE

Unit Disk



A DISK with RADIUS 1.

see also FIVE DISKS PROBLEM, UNIT CIRCLE, UNIT SQUARE

Unit Fraction

A unit fraction is a FRACTION with NUMERATOR 1, also known as an EGYPTIAN FRACTION. Any RATIONAL NUMBER has infinitely many unit fraction representations, although only finitely many have a given fixed number of terms. Each FRACTION x/y with y ODD has a unit fraction representation in which each DENOMINATOR is ODD (Breusch 1954; Guy 1994, p. 160). Every x/y has a t-term representation where $t = \mathcal{O}(\sqrt{\log y})$ (Vose 1985).

There are a number of ALGORITHMS (including the BINARY REMAINDER METHOD, CONTINUED FRACTION UNIT FRACTION ALGORITHM, GENERALIZED REMAINDER METHOD, GREEDY ALGORITHM, REVERSE GREEDY ALGORITHM, SMALL MULTIPLE METHOD, and SPLITTING ALGORITHM) for decomposing an arbitrary FRACTION into unit fractions.

Woods, F. S. *Higher Geometry: An Introduction to Advanced Methods in Analytic Geometry.* New York: Dover, p. 9, 1961.

Unit Ring

A unit ring is a set together with two BINARY OPERATORS $S(+,*)$ satisfying the following conditions:

1. Additive associativity: For all $a, b, c \in S$, $(a+b)+c = a+(b+c)$,
2. Additive commutativity: For all $a, b \in S$, $a+b = b+a$,
3. Additive identity: There exists an element $0 \in S$ such that for all $a \in S: 0+a = a+0 = a$,
4. Additive inverse: For every $a \in S$, there exists a $-a \in S$ such that $a+(-a) = (-a)+a = 0$,
5. Multiplicative associativity: For all $a, b, c \in S$, $(a*b)*c = a*(b*c)$,
6. Multiplicative identity: There exists an element $1 \in S$ such that for all $a \in S$, $1*a = a*1 = a$,
7. Left and right distributivity: For all $a, b, c \in S$, $a*(b+c) = (a*b)+(a*c)$ and $(b+c)*a = (b*a)+(c*a)$.

Thus, a unit ring is a RING with a multiplicative identity.

Unit Step

see HEAVISIDE STEP FUNCTION

Unit Vector

A VECTOR of unit length. The unit vector $\hat{\mathbf{v}}$ having the same direction as a given (nonzero) vector $\mathbf{v}$ is defined by

$$\hat{\mathbf{v}} \equiv \frac{\mathbf{v}}{|\mathbf{v}|},$$

where $|\mathbf{v}|$ denotes the NORM of $\mathbf{v}$, is the unit vector in the same direction as the (finite) VECTOR $\mathbf{v}$. A unit VECTOR in the $\mathbf{x}_n$ direction is given by

$$\hat{\mathbf{x}}_n \equiv \frac{\frac{\partial \mathbf{r}}{\partial x_n}}{\left|\frac{\partial \mathbf{r}}{\partial x_n}\right|},$$

where $\mathbf{r}$ is the RADIUS VECTOR.

see also NORM, RADIUS VECTOR, VECTOR

Unital

A BLOCK DESIGN of the form $(q^3+1,\ q+1,\ 1)$.

Unitary Group

The unitary group $U_n(q)$ is the set of $n \times n$ UNITARY MATRICES.

see also LIE-TYPE GROUP, UNITARY MATRIX

References

Wilson, R. A. "ATLAS of Finite Group Representation." `http://for.mat.bham.ac.uk/atlas#unit`.

Unitary Matrix

A unitary matrix is a MATRIX U for which

$$\mathsf{U}^\dagger = \mathsf{U}^{-1}, \tag{1}$$

where † denotes the ADJOINT OPERATOR. This guarantees that

$$\mathsf{U}^\dagger\mathsf{U} = 1. \tag{2}$$

Unitary matrices leave the length of a COMPLEX vector unchanged. The product of two unitary matrices is itself unitary. If U is unitary, then so is U^{-1}. A SIMILARITY TRANSFORMATION of a HERMITIAN MATRIX with a unitary matrix gives

$$\begin{aligned}(uau^{-1})^\dagger &= [(ua)(u^{-1})]^\dagger = (u^{-1})^\dagger(ua)^\dagger = (u^\dagger)^\dagger(a^\dagger u^\dagger)\\ &= uau^\dagger = uau^{-1}.\end{aligned} \tag{3}$$

For REAL MATRICES, HERMITIAN is the same as ORTHOGONAL. Unitary matrices are NORMAL MATRICES.

If M is a unitary matrix, then the PERMANENT

$$|\operatorname{perm}(\mathsf{M})| \leq 1 \tag{4}$$

(Minc 1978, p. 25, Vardi 1991).

Unitary Sociable Numbers

SOCIABLE NUMBERS computed using the analog of the RESTRICTED DIVISOR FUNCTION $s^*(n)$ in which only UNITARY DIVISORS are included.

see also SOCIABLE NUMBERS

References

Guy, R. K. "Unitary Aliquot Sequences." §B8 in *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, pp. 63–65, 1994.

Unitary Transformation

A transformation of the form

$$\mathsf{A}' = \mathsf{UAU}^\dagger,$$

where † denotes the ADJOINT OPERATOR.

see also ADJOINT OPERATOR, TRANSFORMATION

Unitary Unimodular Group

see SPECIAL UNITARY GROUP

Unity

The number 1. There are n nth ROOTS OF UNITY, known as the DE MOIVRE NUMBERS.

see also 1, PRIMITIVE ROOT OF UNITY

Univalent Function

A function or transformation f in which $f(z)$ does not overlap z.

Univariate Function

A FUNCTION of a single variable (e.g., $f(x)$, $g(z)$, $\theta(\xi)$, etc.).

see also MULTIVARIATE FUNCTION

Univariate Polynomial

A POLYNOMIAL in a single variable. In common usage, univariate POLYNOMIALS are sometimes simply called "POLYNOMIALS."

see also POLYNOMIAL

Universal Graph

see COMPLETE GRAPH

Universal Statement

A universal statement S is a FORMULA whose FREE variables are all in the scope of universal quantifiers.

Universal Turing Machine

A TURING MACHINE which, by appropriate programming using a finite length of input tape, can act as *any* TURING MACHINE whatsoever.

see CHAITIN'S CONSTANT, HALTING PROBLEM, TURING MACHINE

References

Penrose, R. *The Emperor's New Mind: Concerning Computers, Minds, and the Laws of Physics.* Oxford: Oxford University Press, pp. 51–57, 1989.

Unknot

A closed loop which is not KNOTTED. In the 1930s, by making use of REIDEMEISTER MOVES, Reidemeister first proved that KNOTS exist which are distinct from the unknot. He proved this by COLORING each part of a knot diagram with one of three colors.

The KNOT SUM of two unknots is another unknot.

The JONES POLYNOMIAL of the unknot is defined to give the normalization

$$V(t) = 1.$$

Haken (1961) devised an ALGORITHM to tell if a knot projection is the unknot. The ALGORITHM is so complicated, however, that it has never been implemented. Although it is not immediately obvious, the unknot is a PRIME KNOT.

see also COLORABLE, KNOT, KNOT THEORY, LINK, REIDEMEISTER MOVES, UNKNOTTING NUMBER

References

Haken, W. "Theorie der Normalflachen." *Acta Math.* **105**, 245–375, 1961.

Unknotting Number

The smallest number of times a KNOT must be passed through itself to untie it. Lower bounds can be computed using relatively straightforward techniques, but it is in general difficult to determine exact values. Many unknotting numbers can be determined from a knot's SIGNATURE. A KNOT with unknotting number 1 is a PRIME KNOT (Scharlemann 1985). It is not always true that the unknotting number is achieved in a projection with the minimal number of crossings.

The following table is from Kirby (1997, pp. 88–89), with the values for 10_{139} and 10_{152} taken from Kawamura. The unknotting numbers for 10_{154} and 10_{161} can be found using MENASCO'S THEOREM (Stoimenow 1998).

3_1	1	8_9	1	9_{10}	2 or 3	9_{32}	1 or 2

Untouchable Number

An untouchable number is an INTEGER which is not the sum of the PROPER DIVISORS of any other number. The first few are 2, 5, 52, 88, 96, 120, 124, 146, ... (Sloane's A005114). Erdős has proven that there are infinitely many. It is thought that 5 is the only ODD untouchable number.

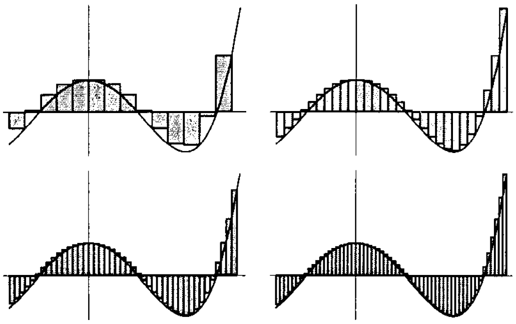
Upper Bound

see LEAST UPPER BOUND

Upper Integral



The limit of an UPPER SUM, when it exists, as the MESH SIZE approaches 0.

see also LOWER INTEGRAL, RIEMANN INTEGRAL, UPPER SUM

Upper Limit

Let the greatest term H of a SEQUENCE be a term which is greater than all but a finite number of the terms which are equal to H. Then H is called the upper limit of the SEQUENCE.

An upper limit of a SERIES

$$\text{upper} \lim_{n\to\infty} S_n = \overline{\lim_{n\to\infty}} S_n = k$$

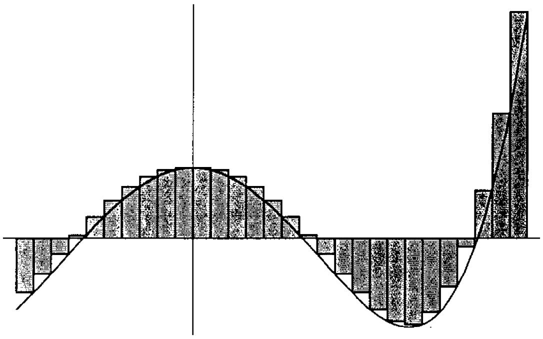
is said to exist if, for every $\epsilon > 0$, $|S_n - k| < \epsilon$ for infinitely many values of n and if no number larger than k has this property.

see also LIMIT, LOWER LIMIT

References

Bromwich, T. J. I'a and MacRobert, T. M. "Upper and Lower Limits of a Sequence." §5.1 in *An Introduction to the Theory of Infinite Series, 3rd ed.* New York: Chelsea, p. 40, 1991.

Upper Sum



For a given function $f(x)$ over a partition of a given interval, the upper sum is the sum of box areas $f(x_k^*)\Delta x_k$ using the greatest value of the function $f(x_k^*)$ in each subinterval Δx_k.

see also LOWER SUM, RIEMANN INTEGRAL, UPPER INTEGRAL

Upper-Trimmed Subsequence

The upper-trimmed subsequence of $x = \{x_n\}$ is the sequence $\lambda(x)$ obtained by dropping the first occurrence of n for each n. If x is a FRACTAL SEQUENCE, then $\lambda(x) = x$.

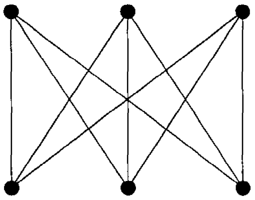
Utility Graph



The utility problem asks, "Can a PLANAR GRAPH be constructed from each of three nodes ('house owners') to each of three other nodes ('wells')?" The answer is no, and the proof can be effected using the JORDAN CURVE THEOREM, while a more general result encompassing this one is the KURATOWSKI REDUCTION THEOREM. The utility graph UG is the graph showing the relationships described above. It is identical to the THOMSEN GRAPH and, in the more formal parlance of GRAPH THEORY, is known as the COMPLETE BIPARTITE GRAPH $K_{3,3}$.

Utility Problem

see UTILITY GRAPH

V

Valence

see VALENCY

Valency

The number of EDGES at a GRAPH VERTEX.

Valuation

A generalization of the p-ADIC NUMBERS first proposed by Kürschák in 1913. A valuation $|\cdot|$ on a FIELD K is a FUNCTION from K to the REAL NUMBERS $\mathbb{R}$ such that the following properties hold for all $x, y \in K$:

1. $|x| \geq 0$,
2. $|x| = 0$ IFF $x = 0$,
3. $|xy| = |x|\,|y|$,
4. $|x| \leq 1$ IMPLIES $|1+x| \leq C$ for some constant $C \geq 1$ (independent of x).

If (4) is satisfied for $C = 2$, then $|\cdot|$ satisfies the TRIANGLE INEQUALITY,

4a. $|x+y| \leq |x| + |y|$ for all $x, y \in K$.

If (4) is satisfied for $C = 1$ then $|\cdot|$ satisfies the stronger TRIANGLE INEQUALITY

4b. $|x+y| \leq \max(|x|, |y|)$.

The simplest valuation is the ABSOLUTE VALUE for REAL NUMBERS. A valuation satisfying (4b) is called non-ARCHIMEDEAN VALUATION; otherwise, it is called ARCHIMEDEAN.

If $|\cdot|_1$ is a valuation on K and $\lambda \geq 1$, then we can define a new valuation $|\cdot|_2$ by

$$|x|_2 = |x|_1^\lambda. \qquad (1)$$

This does indeed give a valuation, but possibly with a different constant C in AXIOM 4. If two valuations are related in this way, they are said to be equivalent, and this gives an equivalence relation on the collection of all valuations on K. Any valuation is equivalent to one which satisfies the triangle inequality (4a). In view of this, we need only to study valuations satisfying (4a), and we often view axioms (4) and (4a) as interchangeable (although this is not strictly true).

If two valuations are equivalent, then they are both non-ARCHIMEDEAN or both ARCHIMEDEAN. $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$ with the usual Euclidean norms are Archimedean valuated fields. For any PRIME p, the p-ADIC NUMBERS $\mathbb{Q}_p$ with the p-adic valuation $|\cdot|_p$ is a non-Archimedean valuated field.

If K is any FIELD, we can define the trivial valuation on K by $|x| = 1$ for all $x \neq 0$ and $|0| = 0$, which is a non-Archimedean valuation. If K is a FINITE FIELD, then the only possible valuation over K is the trivial one. It can be shown that any valuation on $\mathbb{Q}$ is equivalent to one of the following: the trivial valuation, Euclidean absolute norm $|\cdot|$, or p-adic valuation $|\cdot|_p$.

The equivalence of any nontrivial valuation of $\mathbb{Q}$ to either the usual ABSOLUTE VALUE or to a p-ADIC NUMBER absolute value was proved by Ostrowski (1935). Equivalent valuations give rise to the same topology. Conversely, if two valuations have the same topology, then they are equivalent. A stronger result is the following: Let $|\cdot|_1$, $|\cdot|_2$, ..., $|\cdot|_k$ be valuations over K which are pairwise inequivalent and let a_1, a_2, ..., a_k be elements of K. Then there exists an infinite sequence $(x_1, x_2, \ldots)$ of elements of K such that

$$\lim_{n\to\infty \text{ w.r.t. } |\cdot|_1} x_n = a_1 \qquad (2)$$

$$\lim_{n\to\infty \text{ w.r.t. } |\cdot|_2} x_n = a_2, \qquad (3)$$

etc. This says that inequivalent valuations are, in some sense, completely independent of each other. For example, consider the rationals $\mathbb{Q}$ with the 3-adic and 5-adic valuations $|\cdot|_3$ and $|\cdot|_5$, and consider the sequence of numbers given by

$$x_n = \frac{43 \cdot 5^n + 92 \cdot 3^n}{3^n + 5^n}. \qquad (4)$$

Then $x_n \to 43$ as $n \to \infty$ with respect to $|\cdot|_3$, but $x_n \to 92$ as $n \to \infty$ with respect to $|\cdot|_5$, illustrating that a sequence of numbers can tend to two different limits under two different valuations.

A discrete valuation is a valuation for which the VALUATION GROUP is a discrete subset of the REAL NUMBERS $\mathbb{R}$. Equivalently, a valuation (on a FIELD K) is discrete if there exists a REAL NUMBER $\epsilon > 0$ such that

$$|x| \in (1-\epsilon, 1+\epsilon) \Rightarrow |x| = 1 \text{ for all } x \in K. \qquad (5)$$

The p-adic valuation on $\mathbb{Q}$ is discrete, but the ordinary absolute valuation is not.

If $|\cdot|$ is a valuation on K, then it induces a metric

$$d(x,y) = |x-y| \qquad (6)$$

on K, which in turn induces a TOPOLOGY on K. If $|\cdot|$ satisfies (4b) then the metric is an ULTRAMETRIC. We say that $(K, |\cdot|)$ is a complete valuated field if the METRIC SPACE is complete.

Valuation Group

Let $(K, |\cdot|)$ be a valuated field. The valuation group G is defined to be the set

$$G = \{|x| : x \in K, x \neq 0\},$$

with the group operation being multiplication. It is a SUBGROUP of the POSITIVE REAL NUMBERS, under multiplication.

Valuation Ring

Let $(K, |\cdot|)$ be a non-Archimedean valuated field. Its valuation ring R is defined to be

$$R = \{x \in K : |x| \leq 1\}.$$

The valuation ring has maximal IDEAL

$$M = \{x \in K : |x| < 1\},$$

and the field R/M is called the residue field, class field, or field of digits. For example, if $K = \mathbb{Q}_p$ (p-adic numbers), then $R = Z_p$ (p-adic integers), $M = pZ_p$ (p-adic integers congruent to 0 mod p), and $R/M = \mathrm{GF}(p)$, the FINITE FIELD of order p.

Valuation Theory

The study of VALUATIONS which simplifies class field theory and the theory of algebraic function fields.

see also VALUATION

Value

The quantity which a FUNCTION f takes upon application to a given quantity.

see also VALUE (GAME)

Value (Game)

The solution to a GAME in GAME THEORY. When a SADDLE POINT is present

$$\min_{i\leq m} \min_{j\leq n} a_{ij} = \min_{j\leq n} \max_{i\leq m} a_{ij} \equiv v,$$

and v is the value for pure strategies.

see also ABSOLUTE VALUE, GAME THEORY, MINIMAX THEOREM, VALUATION

Vampire Number

A number $v = xy$ with an EVEN number n of DIGITS formed by multiplying a pair of $n/2$-DIGIT numbers (where the DIGITS are taken from the original number in any order) x and y together. Pairs of trailing zeros are not allowed. If v is a vampire number, then x and y are called its "fangs." Examples of vampire numbers include

$$\begin{aligned}1260 &= 21 \times 60\\ 1395 &= 15 \times 93\\ 1435 &= 35 \times 41\\ 1530 &= 30 \times 51\\ 1827 &= 21 \times 87\\ 2187 &= 27 \times 81\\ 6880 &= 80 \times 86\end{aligned}$$

(Sloane's A014575). There are seven 4-digit vampires, 155 6-digit vampires, and 3382 8-digit vampires. General formulas can be constructed for special classes of vampires, such as the fangs

$$\begin{aligned}x &= 25 \cdot 10^k + 1\\ y &= 100(10^{k+1} + 52)/25,\end{aligned}$$

giving the vampire

$$\begin{aligned}v = xy &= (10^{k+1} + 52)10^{k+2} + 100(10^{k+1} + 52)/25\\ &= x^* \cdot 10^{k+2} + t\\ &= 8(26 + 5 \cdot 10^k)(1 + 25 \cdot 10^k),\end{aligned}$$

where x^* denotes x with the DIGITS reversed (Roushe and Rogers).

Pickover (1995) also defines pseudovampire numbers, in which the multiplicands have different number of digits.

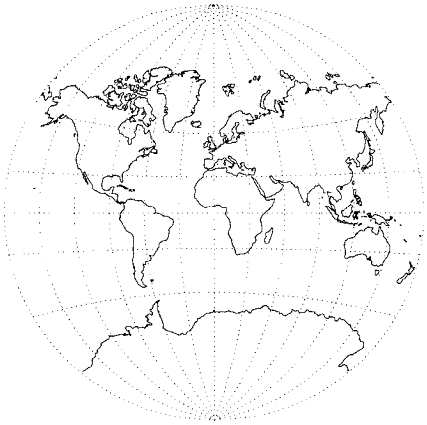
van der Grinten Projection



A MAP PROJECTION given by the transformation

$$x = \operatorname{sgn}(\lambda - \lambda_0)$$
$$\times \frac{\pi|A(G-P^2) - \sqrt{A^2(G-P^2)^2 - (P^2+A^2)(G^2-P^2)}|}{P^2+A^2} \quad (1)$$

$$y = \operatorname{sgn}(\phi) \frac{\pi|PQ - A\sqrt{(A^2+1)(P^2+A^2) - Q^2}}{P^2+A^2}, \quad (2)$$

where

$$A = \frac{1}{2}\left|\frac{\pi}{\lambda-\lambda_0} - \frac{\lambda-\lambda_0}{\pi}\right| \quad (3)$$

$$G = \frac{\cos\theta}{\sin\theta + \cos\theta - 1} \quad (4)$$

$$P = G\left(\frac{2}{\sin\theta} - 1\right) \quad (5)$$

$$\theta = \sin^{-1}\left|\frac{2\phi}{\pi}\right| \quad (6)$$

$$Q = A^2 + G. \quad (7)$$

The inverse FORMULAS are

$$\phi = \operatorname{sgn}(y)\pi\left[-m_1\cos(\theta_1 + \tfrac{1}{3}\pi) - \frac{c_2}{3c_3}\right] \quad (8)$$

$$\lambda = \frac{\pi|X^2+Y^2-1+\sqrt{1+2(X^2-Y^2)+(X^2+Y^2)^2}|}{2X} + \lambda_0, \quad (9)$$

where

$$X = \frac{x}{\pi} \quad (10)$$

$$Y = \frac{y}{\pi} \quad (11)$$

$$c_1 = -|Y|(1+X^2+Y^2) \quad (12)$$

$$c_2 = c_1 - 2Y^2 + X^2 \quad (13)$$

$$c_3 = -2c_1 + 1 + 2Y^2 + (X^2+Y^2)^2 \quad (14)$$

$$d = \frac{Y^2}{c_3} + \frac{1}{27}\left(\frac{2{c_2}^3}{{c_3}^3} - \frac{9c_1c_2}{{c_3}^2}\right) \quad (15)$$

$$a_1 = \frac{1}{c_3}\left(c_1 - \frac{{c_2}^2}{3c_3}\right) \quad (16)$$

$$m_1 = 2\sqrt{-\tfrac{1}{3}a_1} \quad (17)$$

$$\theta_1 = \tfrac{1}{3}\cos^{-1}\left(\frac{3d}{a_1m_1}\right). \quad (18)$$

Vandermonde Theorem

A special case of GAUSS'S THEOREM with a a NEGATIVE INTEGER $-n$:

$${}_2F_1(-n, b; c; 1) = \frac{(c-b)_n}{(c)_n},$$

where ${}_2F_1(a, b; c; z)$ is a HYPERGEOMETRIC FUNCTION and $(a)_n$ is a POCHHAMMER SYMBOL (Bailey 1935, p. 3).

see also GAUSS'S THEOREM

References

Bailey, W. N. *Generalised Hypergeometric Series.* Cambridge, England: Cambridge University Press, 1935.

Vandiver's Criteria

Let p be a IRREGULAR PRIME, and let $P = rp + 1$ be a PRIME with $P < p^2 - p$. Also let t be an INTEGER such that $t^3 \not\equiv 1 \pmod{P}$. For an IRREGULAR PAIR $(p, 2k)$, form the product

$$Q_{2k} = t^{-rd/2} \prod_{b=1}^{m} (t^{rb} - 1)^{b^{p-1-2k}},$$

where

$$\begin{aligned} m &= \tfrac{1}{2}(pl - 1) \\ d &= \sum_{n=1}^{m} n^{p-2k}. \end{aligned}$$

If ${Q_{2k}}^r \not\equiv 1 \pmod{P}$ for all such IRREGULAR PAIRS, then FERMAT'S LAST THEOREM holds for exponent p.

Variance

For N samples of a variate having a distribution with *known* MEAN μ, the "population variance" (usually called "variance" for short, although the word "population" should be added when needed to distinguish it from the SAMPLE VARIANCE) is defined by

$$\begin{aligned} \operatorname{var}(x) &\equiv \frac{1}{N}\sum (x-\mu)^2 = \left\langle x^2 - 2\mu x + \mu^2 \right\rangle \\ &= \left\langle x^2 \right\rangle - \langle 2\mu x \rangle + \left\langle \mu^2 \right\rangle \\ &= \left\langle x^2 \right\rangle - 2\mu \langle x \rangle + \mu^2, \end{aligned} \tag{1}$$

where

$$\langle x \rangle \equiv \frac{1}{N}\sum_{i=1}^{N} x_i. \tag{2}$$

But since $\langle x \rangle$ is an UNBIASED ESTIMATOR for the MEAN

$$\mu \equiv \langle x \rangle, \tag{3}$$

it follows that the variance

$$\sigma^2 \equiv \operatorname{var}(x) = \left\langle x^2 \right\rangle - \mu^2. \tag{4}$$

The population STANDARD DEVIATION is then defined as

$$\sigma \equiv \sqrt{\operatorname{var}(x)} = \sqrt{\langle x^2 \rangle - \mu^2}. \tag{5}$$

A useful identity involving the variance is

$$\operatorname{var}(f(x)+g(x)) = \operatorname{var}(f(x)) + \operatorname{var}(g(x)). \tag{6}$$

Therefore,

$$\begin{aligned} \operatorname{var}(ax+b) &= \left\langle [(ax+b) - \langle ax+b \rangle]^2 \right\rangle \\ &= \left\langle (ax+b-a\langle x \rangle - b)^2 \right\rangle \\ &= \left\langle (ax-a\mu)^2 \right\rangle = \left\langle a^2(x-\mu)^2 \right\rangle \\ &= a^2 \left\langle (x-\mu)^2 \right\rangle = a^2 \operatorname{var}(x) \qquad (7) \\ \operatorname{var}(b) &= 0. \qquad (8) \end{aligned}$$

If the population MEAN is not known, using the sample mean $\bar{x}$ instead of the population mean μ to compute

$$s^2 \equiv \hat{\sigma}_N^2 \equiv \frac{1}{N}\sum_{i=1}^{N}(x_i - \bar{x})^2 \tag{9}$$

gives a BIASED ESTIMATOR of the population variance. In such cases, it is appropriate to use a STUDENT'S t-DISTRIBUTION instead of a GAUSSIAN DISTRIBUTION. However, it turns out (as discussed below) that an UNBIASED ESTIMATOR for the population variance is given by

$$s'^2 \equiv \hat{\sigma}_N'^2 \equiv \frac{1}{N-1}\sum_{i=1}^{N}(x_i - \bar{x})^2. \tag{10}$$

The MEAN and VARIANCE of the sample standard deviation for a distribution with population mean μ and VARIANCE are

$$\mu_{s_N{}^2} = \frac{N-1}{N} s^2 \tag{11}$$

$$\sigma_{s_N{}^2}{}^2 = \frac{N-1}{N^3}[(N-1)\mu_4 - (N-3)\mu_2{}^2]. \tag{12}$$

The quantity $N s_N{}^2/\sigma^2$ has a CHI-SQUARED DISTRIBUTION.

For multiple variables, the variance is given using the definition of COVARIANCE,

$$\begin{aligned} \operatorname{var}\left(\sum_{i=1}^{n} x_i\right) &= \operatorname{cov}\left(\sum_{i=1}^{n} x_i, \sum_{j=1}^{m} x_j\right) \\ &= \sum_{i=1}^{n}\sum_{j=1}^{m} \operatorname{cov}(x_i, x_j) \\ &= \sum_{i=1}^{n}\sum_{\substack{j=1 \\ j=i}}^{m} \operatorname{cov}(x_i, x_j) + \sum_{i=1}^{n}\sum_{\substack{j=1 \\ j\neq i}}^{m} \operatorname{cov}(x_i, x_j) \\ &= \sum_{i=1}^{n} \operatorname{cov}(x_i, x_j) + \sum_{i=1}^{n}\sum_{\substack{j=1 \\ j\neq i}}^{m} \operatorname{cov}(x_i, x_j) \\ &= \sum_{i=1}^{n} \operatorname{var}(x_i) + 2\sum_{i=1}^{n}\sum_{j=i+1}^{m} \operatorname{cov}(x_i, x_j). \end{aligned} \tag{13}$$

A linear sum has a similar form:

$$\begin{aligned} \operatorname{var}\left(\sum_{i=1}^{n} a_i x_i\right) &= \operatorname{cov}\left(\sum_{i=1}^{n} a_i x_i, \sum_{j=1}^{m} a_j x_j\right) \\ &= \sum_{i=1}^{n}\sum_{j=1}^{m} a_i a_j \operatorname{cov}(x_i, x_j) \\ &= \sum_{i=1}^{n} a_i{}^2 \operatorname{var}(x_i) + 2\sum_{i=1}^{n}\sum_{j=i+1}^{m} a_i a_j \operatorname{cov}(x_i, x_j). \end{aligned} \tag{14}$$

These equations can be expressed using the COVARIANCE MATRIX.

To estimate the population VARIANCE from a sample of N elements with a priori *unknown* MEAN (i.e., the MEAN is estimated from the sample itself), we need an

UNBIASED ESTIMATOR for σ. This is given by the k-STATISTIC k_2, where

$$k_2 = \frac{N}{N-1} m_2 \tag{15}$$

and $m_2 \equiv s^2$ is the SAMPLE VARIANCE

$$s^2 \equiv \frac{1}{N} \sum_{i=1}^{N} (x_i - \bar{x})^2. \tag{16}$$

Note that some authors prefer the definition

$$s'^2 \equiv \frac{1}{N-1} \sum_{i=1}^{N} (x_i - \bar{x})^2, \tag{17}$$

since this makes the sample variance an UNBIASED ESTIMATOR for the population variance.

When computing numerically, the MEAN must be computed before s^2 can be determined. This requires storing the set of sample values. It is possible to calculate s'^2 using a recursion relationship involving only the last sample as follows. Here, use μ_j to denote μ calculated from the first j samples (*not* the jth MOMENT)

$$\mu_j \equiv \frac{\sum_{i=1}^{j} x_i}{j}, \tag{18}$$

and $s_j{}^2$ denotes the value for the sample variance s'^2 calculated from the first j samples. The first few values calculated for the MEAN are

$$\mu_1 = x_1 \tag{19}$$

$$\mu_2 = \frac{1 \cdot \mu_1 + x_2}{2} \tag{20}$$

$$\mu_3 = \frac{2\mu_2 + x_3}{3}. \tag{21}$$

Therefore, for $j = 2, 3$ it is true that

$$\mu_j = \frac{(j-1)\mu_{j-1} + x_j}{j}. \tag{22}$$

Therefore, by induction,

$$\begin{aligned} \mu_{j+1} &= \frac{[(j+1)-1]\mu_{(j+1)-1} + x_{j+1}}{j+1} \\ &= \frac{j\mu_j + x_{j+1}}{j+1} \qquad (23) \\ \mu_{j+1}(j+1) &= (j+1)\mu_j + (x_{j+1} - \mu_j) \qquad (24) \\ \mu_{j+1} &= \mu_j + \frac{x_{j+1} - \mu_j}{j+1}, \qquad (25) \end{aligned}$$

and

$$s_j{}^2 = \frac{\sum_{i=1}^{j} (x_i - \mu_j)^2}{j-1} \tag{26}$$

for $j \geq 2$, so

$$\begin{aligned} j s_{j+1}{}^2 &= j \frac{\sum_{i=1}^{j+1} (x_i - \mu_{j+1})^2}{j} = \sum_{i=1}^{j+1} (x_i - \mu_{j+1})^2 \\ &= \sum_{i=1}^{j+1} [(x_i - \mu_j)(\mu_j - \mu_{j+1})]^2 \\ &= \sum_{i=1}^{j+1} (x_i - \mu_j)^2 + \sum_{i=1}^{j+1} (\mu_j - \mu_{j+1})^2 \\ &\quad + 2 \sum_{i=1}^{j+1} (x_i - \mu_j)(\mu_j - \mu_{j+1}). \qquad (27) \end{aligned}$$

Working on the first term,

$$\begin{aligned} \sum_{i=1}^{j+1} (x_i - \mu_j)^2 &= \sum_{i=1}^{j} (x_i - \mu_j)^2 + (x_{j+1} - \mu_j)^2 \\ &= (j-1) s_j{}^2 + (x_{j+1} - \mu_j)^2. \qquad (28) \end{aligned}$$

Use (24) to write

$$x_{j+1} - \mu_j = (j+1)(\mu_{j+1} - \mu_j), \tag{29}$$

so

$$\sum_{i=1}^{j+1} (x_i - \mu_j)^2 = (j-1) s_j{}^2 + (j+1)^2 (\mu_{j+1} - \mu_j)^2. \tag{30}$$

Now work on the second term in (27),

$$\sum_{i=1}^{j+1} (\mu_j - \mu_{j+1})^2 = (j+1)(\mu_j - \mu_{j+1})^2. \tag{31}$$

Considering the third term in (27),

$$\begin{aligned} \sum_{i=1}^{j+1} (x_i - \mu_j)(\mu_j - \mu_{j+1}) &= (\mu_j - \mu_{j+1}) \sum_{i=1}^{j+1} (x_i - \mu_j) \\ &= (\mu_j - \mu_{j+1}) \left[\sum_{i=1}^{j} (x_i - \mu_j) + (x_{j+1} - \mu_j) \right] \\ &= (\mu_j - \mu_{j+1}) \left(x_{j+1} - \mu_j - j\mu_j + \sum_{i=1}^{j} x_i \right). \qquad (32) \end{aligned}$$

But

$$\sum_{i=1}^{j} x_i = j\mu_j, \tag{33}$$

so

$$\begin{aligned} &\sum_{i=1}^{j+1} (\mu_j - \mu_{j+1})(x_{j+1} - \mu_j) \\ &\quad = \sum_{i=1}^{j+1} (\mu_j - \mu_{j+1})(j+1)(\mu_{j+1} - \mu_j) \\ &\quad = -(j+1)(\mu_j - \mu_{j+1})^2. \qquad (34) \end{aligned}$$

Plugging (30), (31), and (34) into (27),

$$\begin{aligned} j{s_{j+1}}^2 &= [(j-1){s_j}^2 + (j+1)^2(\mu_{j+1}-\mu_j)^2] \\ &\quad + [(j+1)(\mu_j-\mu_{j+1}) + 2[-(j+1)(\mu_j-\mu_{j+1})] \\ &= (j-1){s_j}^2 + (j+1)^2(\mu_{j+1}-\mu_j)^2 \\ &\quad - (j+1)(\mu_j-\mu_{j+1})^2 \\ &= (j-1){s_j}^2 + (j+1)[(j+1)-1](\mu_{j+1}-\mu_j)^2 \\ &= (j-1){s_j}^2 + j(j+1)(\mu_{j+1}-\mu_j)^2, \qquad (35) \end{aligned}$$

so

$${s_{j+1}}^2 = \left(1-\frac{1}{j}\right){s_j}^2 + (j+1)(\mu_{j+1}-\mu_j)^2. \qquad (36)$$

To find the variance of s^2 itself, remember that

$$\operatorname{var}(s^2) \equiv \left\langle s^4\right\rangle - \left\langle s^2\right\rangle^2, \qquad (37)$$

and

$$\left\langle s^2\right\rangle = \frac{N-1}{N}\mu_2. \qquad (38)$$

Now find $\left\langle s^4\right\rangle$.

$$\begin{aligned} \left\langle s^4\right\rangle &= \left\langle (s^2)^2\right\rangle = \left\langle (\langle x^2\rangle - \langle x\rangle^2)^2\right\rangle \\ &= \left\langle \left[\frac{1}{N}\sum {x_i}^2 - \left(\frac{1}{N}\sum x_i\right)^2\right]^2\right\rangle \\ &= \frac{1}{N^2}\left\langle \left(\sum x_i\right)^2\right\rangle - \frac{2}{N^3}\left\langle \sum {x_i}^2\left(\sum x_i\right)^2\right\rangle \\ &\quad + \frac{1}{N^4}\left\langle \left(\sum x_i\right)^4\right\rangle. \qquad (39) \end{aligned}$$

Working on the first term of (39),

$$\begin{aligned} \left\langle \left(\sum {x_i}^2\right)^2\right\rangle &= \left\langle \sum {x_i}^4 + \sum {x_i}^2{x_j}^2\right\rangle \\ &= \left\langle \sum {x_i}^4\right\rangle + \left\langle \sum {x_i}^2{x_j}^2\right\rangle \\ &= N\left\langle {x_i}^4\right\rangle + N(N-1)\left\langle {x_i}^2\right\rangle\left\langle {x_j}^2\right\rangle \\ &= N\mu_4' + N(N-1){\mu_2'}^2. \qquad (40) \end{aligned}$$

The second term of (39) is known from k-STATISTICS,

$$\left\langle \sum {x_i}^2\left(\sum x_j\right)^2\right\rangle = N\mu_4' + N(N-1){\mu_2'}^2, \qquad (41)$$

as is the third term,

$$\begin{aligned} \left\langle \left(\sum x_i\right)^4\right\rangle &= N\left\langle \sum {x_i}^4\right\rangle + 3N(N-1)\left\langle \sum {x_i}^2{x_j}^2\right\rangle \\ &= N\mu_4' + 3N(N-1){\mu_2'}^2. \qquad (42) \end{aligned}$$

Combining (39)-(42) gives

$$\begin{aligned} \left\langle s^4\right\rangle &= \frac{1}{N^2}[N\mu_4' + N(N-1){\mu_2'}^2] \\ &\quad - \frac{2}{N^3}[N\mu_4' + N(N-1){\mu_2'}^2] \\ &\quad + \frac{1}{N^4}[N\mu_4' + 3N(N-1){\mu_2'}^2] \\ &= \left(\frac{1}{N} - \frac{2}{N^2} + \frac{1}{N^3}\right)\mu_4' \\ &\quad + \left[\frac{N-1}{N} - \frac{2(N-1)}{N^2} + \frac{3(N-1)}{N^3}\right]{\mu_2'}^2 \\ &= \left(\frac{N^2-2N+1}{N^3}\right)\mu_4' \\ &\quad + \frac{(N-1)(N^2-2N+3)}{N^3}{\mu_2'}^2 \\ &= \frac{(N-1)[(N-1)\mu_4' + (N^2-2N+3){\mu_2'}^2]}{N^3}, \end{aligned} \qquad (43)$$

so plugging in (38) and (43) gives

$$\begin{aligned} \operatorname{var}(s^2) &= \left\langle s^4\right\rangle - \left\langle s^2\right\rangle^2 \\ &= \frac{(N-1)[(N-1)\mu_4' + (N^2-2N+3){\mu_2'}^2]}{N^3} \\ &\quad - \frac{(N-1)^2N}{N^3}{\mu_2'}^2 \\ &= \frac{N-1}{N^3}\{(N-1)\mu_4' + [(N^2-2N+3) \\ &\quad - N(N-1)]{\mu_2'}^2\} \\ &= \frac{(N-1)[(N-1)\mu_4' - (N-3){\mu_2'}^2]}{N^3}. \qquad (44) \end{aligned}$$

Student calculated the SKEWNESS and KURTOSIS of the distribution of s^2 as

$$\gamma_1 = \sqrt{\frac{8}{N-1}} \qquad (45)$$

$$\gamma_2 = \frac{12}{N-1} \qquad (46)$$

and conjectured that the true distribution is PEARSON TYPE III DISTRIBUTION

$$f(s^2) = C(s^2)^{(N-3)/2}e^{-Ns^2/2\sigma^2}, \qquad (47)$$

where

$$\sigma^2 = \frac{Ns^2}{N-1} \qquad (48)$$

$$C = \frac{\left(\frac{N}{2\sigma^2}\right)^{(N-1)/2}}{\Gamma\left(\frac{N-1}{2}\right)}. \qquad (49)$$

This was proven by R. A. Fisher.

The distribution of s itself is given by

$$f(s) = 2\frac{\left(\frac{N}{2\sigma^2}\right)^{(N-1)/2}}{\Gamma\left(\frac{N-1}{2}\right)} e^{-ns^2/2\sigma^2} s^{N-2} \qquad (50)$$

$$\langle s\rangle = \sqrt{\frac{2}{N}}\frac{\Gamma\left(\frac{N}{2}\right)}{\Gamma\left(\frac{N-1}{2}\right)}\sigma \equiv b(N)\sigma, \qquad (51)$$

where

$$b(N) \equiv \sqrt{\frac{2}{N}}\frac{\Gamma\left(\frac{N}{2}\right)}{\Gamma\left(\frac{N-1}{2}\right)}. \qquad (52)$$

The MOMENTS are given by

$$\mu_r = \left(\frac{2}{N}\right)^{r/2}\frac{\Gamma\left(\frac{N-1+r}{2}\right)}{\Gamma\left(\frac{N-1}{2}\right)}\sigma^r, \qquad (53)$$

and the variance is

$$\begin{aligned}\operatorname{var}(s) = \nu_2 - {\nu_1}^2 &= \frac{N-1}{N}\sigma^2 - [b(N)\sigma]^2 \\ &= \frac{1}{N}\left[N-1-\frac{2\Gamma^2\left(\frac{N}{2}\right)}{\Gamma^2\left(\frac{N-1}{2}\right)}\sigma^2\right]. \qquad (54)\end{aligned}$$

An UNBIASED ESTIMATOR of σ is $s/b(N)$. Romanovsky showed that

$$b(N) = 1 - \frac{3}{4N} - \frac{7}{32N^2} - \frac{139}{51849N^3} + \ldots. \qquad (55)$$

Variate

A RANDOM VARIABLE in statistics.

Variation

The Δ-variation is a variation in which the varied path over which an integral is evaluated may end at different times than the correct path, and there may be variation in the coordinates at the endpoints.

The δ-variation is a variation in which the varied path in configuration space terminates at the endpoints representing the system configuration at the same time t_1 and t_2 as the correct path; i.e., the varied path always returns to the same endpoints in configuration space, so

$$\delta q_i(t_1) = \delta q_i(t_2) = 0.$$

see also CALCULUS OF VARIATIONS, VARIATION OF ARGUMENT, VARIATION OF PARAMETERS

Variation of Argument

Let $[\arg f(z)]$ denote the change in argument of a function $f(z)$ around a closed loop γ. Also let N denote the number of ROOTS of $f(z)$ in γ and P denote the number of POLES of $f(z)$ in γ. Then

$$[\arg f(z)] = \frac{1}{2\pi}(N-P). \qquad (1)$$

To find $[\arg f(z)]$ in a given region R, break R into paths and find $[\arg f(z)]$ for each path. On a circular ARC

$$z = Re^{i\theta}, \qquad (2)$$

let $f(z)$ be a POLYNOMIAL $P(z)$ of degree n. Then

$$\begin{aligned}[\arg P(z)] &= \left[\arg\left(z^n\frac{P(z)}{z^n}\right)\right] \\ &= [\arg z^n] + \left[\arg\left(\frac{P(z)}{z^n}\right)\right]. \qquad (3)\end{aligned}$$

Plugging in $z = Re^{i\theta}$ gives

$$[\arg P(z)] = [\arg Re^{i\theta n}] + \left[\arg\frac{P(Re^{i\theta})}{Re^{i\theta n}}\right] \qquad (4)$$

$$\lim_{R\to\infty}\frac{P(Re^{i\theta})}{Re^{i\theta n}} = [\text{constant}], \qquad (5)$$

so

$$\left[\frac{P(Re^{i\theta})}{Re^{i\theta n}}\right] = 0, \qquad (6)$$

and

$$[\arg P(z)] = [\arg e^{i\theta n}] = n(\theta_2 - \theta_1). \qquad (7)$$

For a REAL segment $z = x$,

$$[\arg f(x)] = \tan^{-1}\left[\frac{0}{f(x)}\right] = 0. \qquad (8)$$

For an IMAGINARY segment $z = iy$,

$$[\arg f(iy)] = \left\{\tan^{-1}\frac{\Im[P(iy)]}{\Re[P(iy)]}\right\}_{\theta_1}^{\theta_2}. \qquad (9)$$

Note that the ARGUMENT must change continuously, so "jumps" occur across inverse tangent asymptotes.

Variation Coefficient

If s_x is the STANDARD DEVIATION of a set of samples x_i and $\bar{x}$ its MEAN, then

$$V \equiv \frac{s_x}{\bar{x}}.$$

Variation of Parameters

For a second-order ORDINARY DIFFERENTIAL EQUATION,

$$y'' + p(x)y' + q(x)y = g(x). \tag{1}$$

Assume that linearly independent solutions $y_1(x)$ and $y_2(x)$ are known. Find v_1 and v_2 such that

$$y^*(x) = v_1(x)y_1(x) + v_2(x)y_2(x) \tag{2}$$
$$y^{*\prime}(x) = (v_1' + v_2'y_2) + (v_1y_1' + v_2y_2'). \tag{3}$$

Now, impose the additional condition that

$$v_1'y_1 + v_2'y_2 = 0 \tag{4}$$

so that

$$y^{*\prime}(x) = (v_1y_1' + v_2y_2') \tag{5}$$
$$y^{*\prime\prime}(x) = v_1'y_1' + v_2'y_2' + v_1y_1'' + v_2y_2'. \tag{6}$$

Plug y^*, $y^{*\prime}$, and $y^{*\prime\prime}$ back into the original equation to obtain

$$v_1(y_1''+py_1'+qy_1)+v_2(y_2''+py_2'+qy_2)+v_1'y_1'+v_2'y_2' = g(x) \tag{7}$$
$$v_1'y_1' + v_2'y_2' = g(x). \tag{8}$$

Therefore,

$$v_1'y_1 + v_2'y_2 = 0 \tag{9}$$
$$v_1'y_1' + v_2'y_2' = g(x). \tag{10}$$

Generalizing to an nth degree ODE, let y_1, ..., y_n be the solutions to the homogeneous ODE and let $v_1'(x)$, ..., $v_n'(x)$ be chosen such that

$$\begin{cases} y_1v_1' + y_2v_2' + \ldots + y_nv_n' = 0 \\ y_1'v_1' + y_2'v_2' + \ldots + y_n'v_n' = 0 \\ \vdots \\ y_1^{(n-1)}v_1' + y_2^{(n-1)}v_2' + \ldots + y_n^{(n-1)}v_n' = g(x). \end{cases} \tag{11}$$

Then the particular solution is

$$y^*(x) = v_1(x)y_1(x) + \ldots + v_n(x)y_n(x). \tag{12}$$

Variety

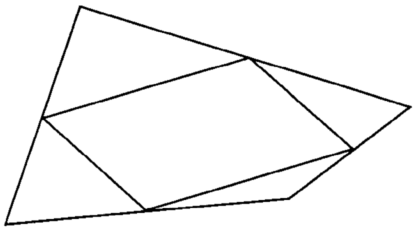
Varignon Parallelogram



The figure formed when the BIMEDIANS (MIDPOINTS of the sides) of a convex QUADRILATERAL are joined. VARIGNON'S THEOREM demonstrated that this figure is a PARALLELOGRAM. The center of the Varignon parallelogram is the CENTROID if four point masses are placed on the VERTICES of the QUADRILATERAL.

see also MIDPOINT, PARALLELOGRAM, QUADRILATERAL, VARIGNON'S THEOREM

Varignon's Theorem

The figure formed when the BIMEDIANS (MIDPOINTS of the sides) of a convex QUADRILATERAL are joined in order is a PARALLELOGRAM. Equivalently, the BIMEDIANS bisect each other. The AREA of this VARIGNON PARALLELOGRAM is half that of the QUADRILATERAL. The PERIMETER is equal to the sum of the diagonals of the original QUADRILATERAL.

see also BIMEDIAN, MIDPOINT, QUADRILATERAL, VARIGNON PARALLELOGRAM

Vassiliev Polynomial

Vassiliev (1990) introduced a radically new way of looking at KNOTS by considering a multidimensional space in which each point represents a possible 3-D knot configuration. If two KNOTS are equivalent, a path then exists in this space from one to the other. The paths can be associated with polynomial invariants.

Birman and Lin (1993) subsequently found a way to translate this scheme into a set of rules and list of potential starting points, which makes analysis of Vassiliev polynomials much simpler. Bar-Natan (1995) and Birman and Lin (1993) proved that JONES POLYNOMIALS and several related expressions are directly connected (Peterson 1992). In fact, substituting the POWER series for e^x as the variable in the JONES POLYNOMIAL yields a POWER SERIES whose COEFFICIENTS are Vassiliev polynomials (Birman and Lin 1993). Bar-Natan (1995) also discovered a link with Feynman diagrams (Peterson 1992).

Vector

A vector is a set of numbers $A_0, \ldots, A_n$ that transform as

$$A_i' = a_{ij} A_j. \tag{1}$$

This makes a vector a TENSOR of RANK 1. Vectors are invariant under TRANSLATION, and they reverse sign upon inversion.

A vector is uniquely specified by giving its DIVERGENCE and CURL within a region and its normal component over the boundary, a result known as HELMHOLTZ'S THEOREM (Arfken 1985, p. 79). A vector from a point A to a point B is denoted $\overrightarrow{AB}$, and a vector v may be denoted $\vec{v}$, or more commonly, $\mathbf{v}$.

A vector with unit length is called a UNIT VECTOR and is denoted with a HAT. An arbitrary vector may be converted to a UNIT VECTOR by dividing by its NORM, i.e.,

$$\hat{\mathbf{v}} \equiv \frac{\mathbf{v}}{|\mathbf{v}|}. \tag{2}$$

Let $\hat{\mathbf{n}}$ be the UNIT VECTOR defined by

$$\hat{\mathbf{n}} \equiv \begin{bmatrix} \cos\theta \sin\phi \\ \sin\theta \sin\phi \\ \cos\phi \end{bmatrix}. \tag{3}$$

Then the vectors $\hat{\mathbf{n}}$, $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$, $\mathbf{d}$ satisfy the identities

$$\begin{aligned}
\langle n_x \rangle &= \int_0^{2\pi} \int_0^{\pi} (\cos\theta \sin\phi) \sin\phi \, d\theta \, d\phi \\
&= [\sin\theta]_0^{2\pi} \int_0^{2\pi} \sin^2\phi \, d\phi = 0 && (4) \\
\langle n_i \rangle &= 0 && (5) \\
\langle n_i n_j \rangle &= \tfrac{1}{3}\delta_{ij} && (6) \\
\langle n_i n_k n_k \rangle &= 0 && (7) \\
\langle n_i n_k n_l n_m \rangle &= \tfrac{1}{15}(\delta_{ik}\delta_{lm} + \delta_{il}\delta_{km} + \delta_{im}\delta_{kl}) && (8) \\
\left\langle (\mathbf{a}\cdot\hat{\mathbf{n}})^2 \right\rangle &= \tfrac{1}{3}a^2 && (9) \\
\langle (\mathbf{a}\cdot\hat{\mathbf{n}})(\mathbf{b}\cdot\hat{\mathbf{n}}) \rangle &= \tfrac{1}{3}\mathbf{a}\cdot\mathbf{b} && (10) \\
\langle (\mathbf{a}\cdot\hat{\mathbf{n}})\hat{\mathbf{n}} \rangle &= \tfrac{1}{3}a && (11) \\
\left\langle (\mathbf{a}\times\hat{\mathbf{n}})^2 \right\rangle &= \tfrac{2}{3}a^2 && (12) \\
\langle (\mathbf{a}\times\hat{\mathbf{n}})\cdot(\mathbf{b}\times\hat{\mathbf{n}}) \rangle &= \tfrac{2}{3}\mathbf{a}\cdot\mathbf{b}, && (13)
\end{aligned}$$

and

$$\begin{aligned}
&\langle (\mathbf{a}\cdot\hat{\mathbf{n}})(\mathbf{b}\cdot\hat{\mathbf{n}})(\mathbf{c}\cdot\hat{\mathbf{n}})(\mathbf{d}\cdot\hat{\mathbf{n}}) \rangle \\
&= \tfrac{1}{15}[(bfa\cdot\mathbf{b})(bfc\cdot\mathbf{d}) + (bfa\cdot\mathbf{c})(bfb\cdot\mathbf{d}) + (bfa\cdot\mathbf{d})(bfb\cdot\mathbf{c})] \qquad (14)
\end{aligned}$$

where δ_{ij} is the KRONECKER DELTA, $\mathbf{a}\cdot\mathbf{b}$ is a DOT PRODUCT, and EINSTEIN SUMMATION has been used.

Vector Bundle

A special class of FIBER BUNDLE in which the FIBER is a VECTOR SPACE. Technically, a little more is required; namely, if $f : E \to B$ is a BUNDLE with FIBER $\mathbb{R}^n$, to be a vector bundle, all of the FIBERS $f^{-1}(x)$ for

$x \in B$ need to have a coherent VECTOR SPACE structure. One way to say this is that the "trivializations" $h : f^{-1}(U) \to U \times \mathbb{R}^n$, are FIBER-for-FIBER VECTOR SPACE ISOMORPHISMS.

see also BUNDLE, FIBER, FIBER BUNDLE, LIE ALGEBROID, STABLE EQUIVALENCE, TANGENT MAP, VECTOR SPACE, WHITNEY SUM

Vector Derivative

The basic types of derivatives operating on a VECTOR FIELD are the CURL $\nabla\times$, DIVERGENCE $\nabla\cdot$, and GRADIENT ∇.

Vector derivative identities involving the CURL include

$$\nabla \times (k\mathbf{A}) = k\nabla \times \mathbf{A} \tag{1}$$

$$\nabla \times (f\mathbf{A}) = f(\nabla \times \mathbf{A}) + (\nabla f) \times \mathbf{A} \tag{2}$$

$$\begin{aligned}\nabla \times (\mathbf{A} \times \mathbf{B}) = (\mathbf{B} \cdot \nabla)\mathbf{A} - (\mathbf{A} \cdot \nabla)\mathbf{B} \\ +\mathbf{A}(\nabla \cdot \mathbf{B}) - \mathbf{B}(\nabla \cdot \mathbf{A})\end{aligned} \tag{3}$$

$$\nabla \times \left(\frac{\mathbf{A}}{f}\right) = \frac{f(\nabla \times \mathbf{A}) + \mathbf{A} \times (\nabla f)}{f^2} \tag{4}$$

$$\nabla \times (\mathbf{A} + \mathbf{B}) = \nabla \times \mathbf{A} + \nabla \times \mathbf{B}. \tag{5}$$

In SPHERICAL COORDINATES,

$$\nabla \times \mathbf{r} = \mathbf{0} \tag{6}$$

$$\nabla \times \hat{\mathbf{r}} = \mathbf{0} \tag{7}$$

$$\begin{aligned}\nabla \times [\mathbf{r}f(r)] &= f(r)(\nabla \times \mathbf{r}) + [\nabla f(r)] \times \mathbf{r} \\ &= f(r)(\mathbf{0}) + \frac{df}{dr}\hat{\mathbf{r}} \times \mathbf{r} = \mathbf{0} + \mathbf{0} = \mathbf{0}.\end{aligned} \tag{8}$$

Vector derivative identities involving the DIVERGENCE include

$$\nabla \cdot (k\mathbf{A}) = k\nabla \cdot \mathbf{A} \tag{9}$$

$$\nabla \cdot (f\mathbf{A}) = f(\nabla \cdot \mathbf{A}) + (\nabla f) \cdot \mathbf{A} \tag{10}$$

$$\nabla \cdot (\mathbf{A} \times \mathbf{B}) = \mathbf{B} \cdot (\nabla \times \mathbf{A}) - \mathbf{A} \cdot (\nabla \times \mathbf{B}) \tag{11}$$

$$\nabla \cdot \left(\frac{\mathbf{A}}{f}\right) = \frac{f(\nabla \cdot \mathbf{A}) - (\nabla f) \cdot \mathbf{A}}{f^2} \tag{12}$$

$$\nabla \cdot (\mathbf{A} + \mathbf{B}) = \nabla \cdot \mathbf{A} + \nabla \cdot \mathbf{B} \tag{13}$$

$$\nabla(\mathbf{uv}) = \mathbf{u}\nabla \cdot \mathbf{v} + (\nabla \mathbf{u}) \cdot \mathbf{v}. \tag{14}$$

In SPHERICAL COORDINATES,

$$\nabla \cdot \mathbf{r} = 3 \tag{15}$$

$$\nabla \cdot \hat{\mathbf{r}} = \frac{2}{r} \tag{16}$$

$$\nabla \cdot [\mathbf{r}f(r)] = \frac{\partial}{\partial x}[xf(r)] + \frac{\partial}{\partial y}[yf(r)] + \frac{\partial}{\partial z}[zf(r)] \tag{17}$$

$$\frac{\partial}{\partial x}[xf(r)] = x\frac{\partial f}{\partial x} + f = x\frac{\partial f}{\partial r}\frac{\partial r}{\partial x} + f \tag{18}$$

$$\frac{\partial r}{\partial x} = \frac{\partial}{\partial x}(x^2+y^2+z^2)^{1/2} = x(x^2+y^2+z^2)^{-1/2} = \frac{x}{r} \tag{19}$$

$$\frac{\partial}{\partial x}[xf(r)] = \frac{x^2}{r}\frac{df}{dr} + f. \tag{20}$$

By symmetry,

$$\nabla \cdot [\mathbf{r}f(r)] = 3f(r) + \frac{1}{r}(x^2+y^2+z^2)\frac{df}{dr} = 3f(r) + r\frac{df}{dr} \tag{21}$$

$$\nabla \cdot (\hat{\mathbf{r}}f(r)) = \frac{3}{r}f(r) + \frac{df}{dr} \tag{22}$$

$$\nabla \cdot (\hat{\mathbf{r}}r^n) = 3r^{n-1} + (n-1)r^{n-1} = (n+2)r^{n-1}. \tag{23}$$

Vector derivative identities involving the GRADIENT include

$$\nabla(kf) = k\nabla f \tag{24}$$

$$\nabla(fg) = f\nabla g + g\nabla f \tag{25}$$

$$\begin{aligned}\nabla(\mathbf{A} \cdot \mathbf{B}) = \mathbf{A} \times (\nabla \times \mathbf{B}) + \mathbf{B} \times (\nabla \times \mathbf{A}) \\ +(\mathbf{A} \cdot \nabla)\mathbf{B} + (\mathbf{B} \cdot \nabla)\mathbf{A}\end{aligned} \tag{26}$$

$$\begin{aligned}\nabla(\mathbf{A} \cdot \nabla f) &= \mathbf{A} \times (\nabla \times \nabla f) + \nabla f \times (\nabla \times \mathbf{A}) \\ &\quad +\mathbf{A} \cdot \nabla(\nabla f) + \nabla f \cdot \nabla \mathbf{A} \\ &= \nabla f \times (\nabla \times \mathbf{A}) + \mathbf{A} \cdot \nabla(\nabla f) + \nabla f \cdot \nabla \mathbf{A}\end{aligned} \tag{27}$$

$$\nabla\left(\frac{f}{g}\right) = \frac{g\nabla f - f\nabla g}{g^2} \tag{28}$$

$$\nabla(f+g) = \nabla f + \nabla g \tag{29}$$

$$\nabla(\mathbf{A} \cdot \mathbf{A}) = 2\mathbf{A} \times (\nabla \times \mathbf{A}) + 2(\mathbf{A} \cdot \nabla)\mathbf{A} \tag{30}$$

$$(\mathbf{A} \cdot \nabla)\mathbf{A} = \nabla(\tfrac{1}{2}\mathbf{A}^2) - \mathbf{A} \times (\nabla \times \mathbf{A}). \tag{31}$$

Vector second derivative identities include

$$\nabla^2 t \equiv \nabla \cdot (\nabla t) = \frac{\partial^2 t}{\partial x^2} + \frac{\partial^2 t}{\partial y^2} + \frac{\partial^2 t}{\partial z^2} \tag{32}$$

$$\nabla^2 \mathbf{A} = \nabla(\nabla \cdot \mathbf{A}) - \nabla \times (\nabla \times \mathbf{A}). \tag{33}$$

This very important second derivative is known as the LAPLACIAN.

$$\nabla \times (\nabla t) = \mathbf{0} \tag{34}$$

$$\nabla(\nabla \cdot \mathbf{A}) = \nabla^2\mathbf{A} + \nabla \times (\nabla \times \mathbf{A}) \tag{35}$$

$$\nabla \cdot (\nabla \times \mathbf{A}) = 0 \tag{36}$$

$$\begin{aligned}&\nabla \times (\nabla \times \mathbf{A}) = \nabla(\nabla \cdot \mathbf{A}) - \nabla^2\mathbf{A} \\ &\nabla \times (\nabla^2\mathbf{A}) = \nabla \times [\nabla(\nabla \cdot \mathbf{A})] - \nabla \times [\nabla \times (\nabla \times \mathbf{A})] \\ &\quad = -\nabla \times [\nabla \times (\nabla \times \mathbf{A})] \\ &\quad = -\{\nabla[\nabla \cdot (\nabla \times \mathbf{A})] - \nabla^2(\nabla \times \mathbf{A})]\} \\ &\quad = \nabla^2(\nabla \times \mathbf{A})\end{aligned} \tag{37}$$

$$\begin{aligned}\nabla^2(\nabla \cdot \mathbf{A}) &= \nabla \cdot [\nabla(\nabla \cdot \mathbf{A})] \\ &= \nabla \cdot [\nabla^2\mathbf{A} + \nabla \times (\nabla \times \mathbf{A})] = \nabla \cdot (\nabla^2\mathbf{A})\end{aligned} \tag{38}$$

$$\begin{aligned}\nabla^2[\nabla \times (\nabla \times \mathbf{A})] &= \nabla^2[\nabla(\nabla \cdot \mathbf{A}) - \nabla^2\mathbf{A}] \\ &= \nabla^2[\nabla(\nabla \cdot \mathbf{A})] - \nabla^4\mathbf{A}\end{aligned} \tag{39}$$

$$\nabla \times [\nabla^2(\nabla \times \mathbf{A})] = \nabla^2[\nabla(\nabla \cdot \mathbf{A})] - \nabla^4\mathbf{A} \tag{40}$$

$$\begin{aligned}\nabla^4\mathbf{A} &= -\nabla^2[\nabla \times (\nabla \times \mathbf{A})] + \nabla^2[\nabla(\nabla \cdot \mathbf{A})] \\ &= \nabla \times [\nabla^2(\nabla \times \mathbf{A})] - \nabla^2[\nabla \times (\nabla \times \mathbf{A})].\end{aligned} \tag{41}$$

Combination identities include

$$\mathbf{A} \times (\nabla \mathbf{A}) = \tfrac{1}{2}\nabla(\mathbf{A} \cdot \mathbf{A}) - (\mathbf{A} \cdot \nabla)\mathbf{A} \tag{42}$$

$$\nabla \times (\phi \nabla \phi) = \phi \nabla \times (\nabla \phi) + (\nabla \phi) \times (\nabla \phi) = \mathbf{0} \tag{43}$$

$$(\mathbf{A} \cdot \nabla)\hat{\mathbf{r}} = \frac{\mathbf{A} - \hat{\mathbf{r}}(\mathbf{A} \cdot \hat{\mathbf{r}})}{r} \tag{44}$$

$$\nabla f \cdot \mathbf{A} = \nabla \cdot (f\mathbf{A}) - f(\nabla \cdot \mathbf{A}) \tag{45}$$

$$f(\nabla \cdot \mathbf{A}) = \nabla \cdot (f\mathbf{A}) - \mathbf{A}\nabla f, \tag{46}$$

where (45) and (46) follow from divergence rule (2).

Vector Direct Product

Given VECTORS $\mathbf{u}$ and $\mathbf{v}$, the vector direct product is

$$\mathbf{uv} \equiv \mathbf{u} \otimes \mathbf{v}^{\mathrm{T}},$$

where $\otimes$ is the MATRIX DIRECT PRODUCT and $\mathbf{v}^{\mathrm{T}}$ is the matrix TRANSPOSE. For 3×3 vectors

$$\mathbf{uv} = \begin{bmatrix} u_1\mathbf{v}^{\mathrm{T}} \\ u_2\mathbf{v}^{\mathrm{T}} \\ u_3\mathbf{v}^{\mathrm{T}} \end{bmatrix} = \begin{bmatrix} u_1v_1 & u_1v_2 & u_1v_3 \\ u_2v_1 & u_2v_2 & u_2v_3 \\ u_3v_1 & u_3v_2 & u_3v_3 \end{bmatrix}.$$

Note that if $\mathbf{u} = \hat{\mathbf{x}}_i$, then $u_j = \delta_{ij}$, where δ_{ij} is the KRONECKER DELTA.

see also MATRIX DIRECT PRODUCT, SHERMAN-MORRISON FORMULA, WOODBURY FORMULA

Vector Division

There is no unique solution A to the MATRIX equation $\mathbf{y} = \mathsf{A}\mathbf{x}$ unless $\mathbf{x}$ is PARALLEL to $\mathbf{y}$, in which case A is a SCALAR. Therefore, vector division is not defined.

see also MATRIX, SCALAR

Vector Field

A MAP $\mathbf{f} : \mathbb{R}^n \mapsto \mathbb{R}^n$ which assigns each $\mathbf{x}$ a VECTOR FUNCTION $\mathbf{f}(\mathbf{x})$. FLOWS are generated by vector fields and vice versa. A vector field is a SECTION of its TANGENT BUNDLE.

see also FLOW, SCALAR FIELD, SEIFERT CONJECTURE, TANGENT BUNDLE, VECTOR, WILSON PLUG

Vector Function

A function of one or more variables whose RANGE is 3-dimensional, as compared to a SCALAR FUNCTION, whose RANGE is 1-dimensional.

see also COMPLEX FUNCTION, REAL FUNCTION, SCALAR FUNCTION

Vector Harmonic

see VECTOR SPHERICAL HARMONIC

Vector Integral

The following vector integrals are related to the CURL THEOREM. If

$$\mathbf{F} \equiv \mathbf{c} \times \mathbf{P}(x, y, z), \tag{1}$$

then

$$\int_C d\mathbf{s} \times \mathbf{P} = \int_S (d\mathbf{a} \times \nabla) \times \mathbf{P}. \tag{2}$$

If

$$\mathbf{F} \equiv \mathbf{c}F, \tag{3}$$

then

$$\int_C F\,d\mathbf{s} = \int_S d\mathbf{a} \times \nabla \mathbf{F}. \tag{4}$$

The following are related to the DIVERGENCE THEOREM. If

$$\mathbf{F} \equiv \mathbf{c} \times \mathbf{P}(x, y, z), \tag{5}$$

then

$$\int_V \nabla \times \mathbf{F}\,dV = \int_S d\mathbf{a} \times \mathbf{F}. \tag{6}$$

Finally, if

$$\mathbf{F} \equiv \mathbf{c}F, \tag{7}$$

then

$$\int_V \nabla F\,dV = \int_S F\,d\mathbf{a}. \tag{8}$$

see also CURL THEOREM, DIVERGENCE THEOREM, GRADIENT THEOREM, GREEN'S FIRST IDENTITY, GREEN'S SECOND IDENTITY, LINE INTEGRAL, SURFACE INTEGRAL, VECTOR DERIVATIVE, VOLUME INTEGRAL

Vector Norm

Given an n-D VECTOR

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix},$$

a vector norm $||\mathbf{x}||$ (sometimes written simply $|\mathbf{x}|$) is a NONNEGATIVE number satisfying

1. $||x|| > 0$ when $\mathbf{x} \neq \mathbf{0}$ and $||\mathbf{x}|| = 0$ IFF $\mathbf{x} = \mathbf{0}$,
2. $||k\mathbf{x}|| = |k|\,||\mathbf{x}||$ for any SCALAR k,
3. $||\mathbf{x} + \mathbf{y}|| \leq ||\mathbf{x}|| + ||\mathbf{y}||$.

see also COMPATIBLE, MATRIX NORM, NATURAL NORM, NORM

References

Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products, 5th ed.* San Diego, CA: Academic Press, p. 1114, 1980.

Vector Ordering

If the first NONZERO component of the vector difference $\mathbf{A}-\mathbf{B}$ is >0, then $\mathbf{A}\succ\mathbf{B}$. If the first NONZERO component of $\mathbf{A}-\mathbf{B}$ is <0, then $\mathbf{A}\prec\mathbf{B}$.

see also PRECEDES, SUCCEEDS

Vector Potential

A function $\mathbf{A}$ such that

$$\mathbf{B}\equiv\nabla\times\mathbf{A}.$$

The most common use of a vector potential is the representation of a magnetic field. If a VECTOR FIELD has zero DIVERGENCE, it may be represented by a vector potential.

see also DIVERGENCE, HELMHOLTZ'S THEOREM, POTENTIAL FUNCTION, SOLENOIDAL FIELD, VECTOR FIELD

Vector Quadruple Product

$$(\mathbf{A}\times\mathbf{B})\cdot(\mathbf{C}\times\mathbf{D})=(\mathbf{A}\cdot\mathbf{C})(\mathbf{B}\cdot\mathbf{D})-(\mathbf{A}\cdot\mathbf{D})(\mathbf{B}\cdot\mathbf{C}) \tag{1}$$

$$\begin{aligned}(\mathbf{A}\times\mathbf{B})^2&\equiv(\mathbf{A}\times\mathbf{B})\cdot(\mathbf{A}\times\mathbf{B})\\&=(\mathbf{A}\cdot\mathbf{A})(\mathbf{B}\cdot\mathbf{B})-(\mathbf{A}\cdot\mathbf{B})(\mathbf{B}\cdot\mathbf{A})\\&=\mathbf{A}^2\mathbf{B}^2-(\mathbf{A}\cdot\mathbf{B})^2\end{aligned} \tag{2}$$

$$\mathbf{A}\times(\mathbf{B}\times(\mathbf{C}\times\mathbf{D}))=\mathbf{B}(\mathbf{A}\cdot(\mathbf{C}\times\mathbf{D}))-(\mathbf{A}\cdot\mathbf{B})(\mathbf{C}\times\mathbf{D}) \tag{3}$$

$$\begin{aligned}&(\mathbf{A}\times\mathbf{B})\times(\mathbf{C}\times\mathbf{D})=[\mathbf{A},\mathbf{B},\mathbf{D}]\mathbf{C}-[\mathbf{A},\mathbf{B},\mathbf{C}]\mathbf{D}\\&=(\mathbf{C}\times\mathbf{D})\times(\mathbf{B}\times\mathbf{A})=[\mathbf{C},\mathbf{D},\mathbf{A}]\mathbf{D}-[\mathbf{C},\mathbf{D},\mathbf{B}]\mathbf{A},\end{aligned} \tag{4}$$

where $[\mathbf{A},\mathbf{B},\mathbf{D}]$ denotes the VECTOR TRIPLE PRODUCT. Equation (1) is known as LAGRANGE'S IDENTITY.

see also LAGRANGE'S IDENTITY, VECTOR TRIPLE PRODUCT

Vector Space

A vector space over $\mathbb{R}^n$ is a set of VECTORS for which any VECTORS $\mathbf{X}$, $\mathbf{Y}$, and $\mathbf{Z}\in\mathbb{R}^n$ and any SCALARS r, $s\in\mathbb{R}$ have the following properties:

1. COMMUTATIVITY:

$$\mathbf{X}+\mathbf{Y}=\mathbf{Y}+\mathbf{X}.$$

2. ASSOCIATIVITY of vector addition:

$$(\mathbf{X}+\mathbf{Y})+\mathbf{Z}=\mathbf{X}+(\mathbf{Y}+\mathbf{Z}).$$

3. Additive identity: For all $\mathbf{X}$,

$$\mathbf{0}+\mathbf{X}=\mathbf{X}+\mathbf{0}=\mathbf{X}.$$

4. Existence of additive inverse: For any $\mathbf{X}$, there exists a $-\mathbf{X}$ such that

$$\mathbf{X}+(-\mathbf{X})=\mathbf{0}.$$

5. ASSOCIATIVITY of scalar multiplication:

$$r(s\mathbf{X})=(rs)\mathbf{X}.$$

6. DISTRIBUTIVITY of scalar sums:

$$(r+s)\mathbf{X}=r\mathbf{X}+s\mathbf{X}.$$

7. DISTRIBUTIVITY of vector sums:

$$r(\mathbf{X}+\mathbf{Y})=r\mathbf{X}+r\mathbf{Y}.$$

8. Scalar multiplication identity:

$$1\mathbf{X}=\mathbf{X}.$$

An n-D vector space of characteristic two has

$$S(k,n)=(2^n-2^0)(2^n-2^1)\cdots(2^n-2^{k-1})$$

distinct SUBSPACES of DIMENSION k.

A MODULE is abstractly similar to a vector space, but it uses a RING to define COEFFICIENTS instead of the FIELD used for vector spaces. MODULES have COEFFICIENTS in much more general algebraic objects.

see also BANACH SPACE, FIELD, FUNCTION SPACE, HILBERT SPACE, INNER PRODUCT SPACE, MODULE, RING, TOPOLOGICAL VECTOR SPACE

Arfken, G. *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 530–534, 1985.

Vector Spherical Harmonic

The SPHERICAL HARMONICS can be generalized to vector spherical harmonics by looking for a SCALAR FUNCTION ψ and a constant VECTOR $\mathbf{c}$ such that

$$\begin{aligned}\mathbf{M}&\equiv\nabla\times(\mathbf{c}\psi)=\psi(\nabla\times\mathbf{c})+(\nabla\psi)\times\mathbf{c}\\&=(\nabla\psi)\times\mathbf{c}=-\mathbf{c}\times\nabla,\psi\end{aligned} \tag{1}$$

so

$$\nabla\cdot\mathbf{M}=0. \tag{2}$$

Now use the vector identities

$$\begin{aligned}\nabla^2\mathbf{M}&=\nabla^2(\nabla\times\mathbf{M})=\nabla\times(\nabla^2\mathbf{M})\\&=\nabla\times(\nabla^2\mathbf{c}\psi)=\nabla\times(\mathbf{c}\nabla^2\psi)\end{aligned} \tag{3}$$

$$k^2\mathbf{M}=k^2\nabla\times(\mathbf{c}\psi)=\nabla\times(\mathbf{c}\nabla^2\psi), \tag{4}$$

so

$$\nabla^2\mathbf{M} + k^2\mathbf{M} = \nabla \times [\mathbf{c}(\nabla^2\psi + k^2\psi)], \tag{5}$$

and $\mathbf{M}$ satisfies the vector HELMHOLTZ DIFFERENTIAL EQUATION if ψ satisfies the scalar HELMHOLTZ DIFFERENTIAL EQUATION

$$\nabla^2\psi + k^2\psi = 0. \tag{6}$$

Construct another vector function

$$\mathbf{N} \equiv \frac{\nabla \times \mathbf{M}}{k}, \tag{7}$$

which also satisfies the vector HELMHOLTZ DIFFERENTIAL EQUATION since

$$\begin{aligned}\nabla^2\mathbf{N} &= \frac{1}{k}\nabla^2(\nabla \times \mathbf{M}) = \frac{1}{k}\nabla \times (\nabla^2\mathbf{M})\\ &= \frac{1}{k}\nabla \times (-k^2\mathbf{M}) = -k\nabla \times \mathbf{M} = -k^2\mathbf{N},\end{aligned} \tag{8}$$

which gives

$$\nabla^2\mathbf{N} + k^2\mathbf{N} = 0. \tag{9}$$

We have the additional identity

$$\begin{aligned}\nabla \times \mathbf{N} &= \frac{1}{k}\nabla \times (\nabla \times \mathbf{M}) = \frac{1}{k}\nabla(\nabla \cdot \mathbf{M})\\ &= \frac{1}{k}\nabla^2\mathbf{M} - \frac{1}{k}\nabla^2\mathbf{M} = \frac{-\nabla^2\mathbf{M}}{k} = k\mathbf{M}.\end{aligned} \tag{10}$$

In this formalism, ψ is called the generating function and $\mathbf{c}$ is called the PILOT VECTOR. The choice of generating function is determined by the symmetry of the scalar equation, i.e., it is chosen to solve the desired scalar differential equation. If $\mathbf{M}$ is taken as

$$\mathbf{M} = \nabla \times (\mathbf{r}\psi), \tag{11}$$

where $\mathbf{r}$ is the radius vector, then $\mathbf{M}$ is a solution to the vector wave equation in spherical coordinates. If we want vector solutions which are tangential to the radius vector,

$$\mathbf{M} \cdot \mathbf{r} = \mathbf{r} \cdot (\nabla\psi \times \mathbf{c}) = (\nabla\psi)(\mathbf{c} \times \mathbf{r}) = 0, \tag{12}$$

so

$$\mathbf{c} \times \mathbf{r} = \mathbf{0} \tag{13}$$

and we may take

$$\mathbf{c} = \mathbf{r} \tag{14}$$

(Arfken 1985, pp. 707–711; Bohren and Huffman 1983, p. 88).

A number of conventions are in use. Hill (1954) defines

$$\begin{aligned}\mathbf{V}_l^m &\equiv -\sqrt{\frac{l+1}{2l+1}}Y_l^m\hat{\mathbf{r}} + \frac{1}{\sqrt{(l+1)(2l+1)}}\frac{\partial Y_l^m}{\partial\theta}\hat{\boldsymbol{\theta}}\\ &\quad + iM\sqrt{(l+1)(2l+1)}\sin\theta Y_l^m\hat{\boldsymbol{\phi}}\end{aligned} \tag{15}$$

$$\begin{aligned}\mathbf{W}_l^m &= \sqrt{\frac{l}{2l+1}}Y_l^m\hat{\mathbf{r}} + \frac{1}{\sqrt{l(2l+1)}}\frac{\partial Y_l^m}{\partial\theta}\hat{\boldsymbol{\theta}}\\ &\quad + \frac{iM}{\sqrt{l(2l+1)}\sin\theta}Y_l^m\hat{\boldsymbol{\phi}}\end{aligned} \tag{16}$$

$$\mathbf{X}_l^m = -\frac{M}{\sqrt{l(l+1)}\sin\theta}Y_l^m\hat{\boldsymbol{\theta}} - \frac{i}{\sqrt{l(l+1)}}\frac{\partial Y_l^m}{\partial\theta}\hat{\boldsymbol{\phi}}. \tag{17}$$

Morse and Feshbach (1953) define vector harmonics called $\mathbf{B}$, $\mathbf{C}$, and $\mathbf{P}$ using rather complicated expressions.

Vector Transformation Law

The set of n quantities v_j are components of an n-D VECTOR $\mathbf{v}$ IFF, under ROTATION,

$$v_i' = a_{ij}v_j$$

for $i = 1, 2, \ldots, n$. The DIRECTION COSINES between x_i' and x_j are

$$a_{ij} \equiv \frac{\partial x_i'}{\partial x_j} = \frac{\partial x_j}{\partial x_i'}.$$

They satisfy the orthogonality condition

$$a_{ij}a_{ik} = \frac{\partial x_j}{\partial x_i'}\frac{\partial x_i'}{\partial x_k} = \frac{\partial x_j}{\partial x_k} = \delta_{jk},$$

where δ_{jk} is the KRONECKER DELTA.

see also TENSOR, VECTOR

Vector Triple Product

The triple product can be written in terms of the Levi-Civita Symbol ϵ_{ijk} as

$$\mathbf{A}\cdot(\mathbf{B}\times\mathbf{C})=\epsilon_{ijk}A^iB^jC^k. \tag{1}$$

The BAC-CAB Rule can be written in the form

$$\mathbf{A}\times(\mathbf{B}\times\mathbf{C})=\mathbf{B}(\mathbf{A}\cdot\mathbf{C})-\mathbf{C}(\mathbf{A}\cdot\mathbf{B}) \tag{2}$$

$$\begin{aligned}(\mathbf{A}\times\mathbf{B})\times\mathbf{C}&=-\mathbf{C}\times(\mathbf{A}\times\mathbf{B})\\&=-\mathbf{A}(\mathbf{B}\cdot\mathbf{C})+\mathbf{B}(\mathbf{A}\cdot\mathbf{C}).\end{aligned} \tag{3}$$

Addition identities are

$$\mathbf{A}\cdot(\mathbf{B}\times\mathbf{C})=\mathbf{B}\cdot(\mathbf{C}\times\mathbf{A})=\mathbf{C}\cdot(\mathbf{A}\times\mathbf{B}) \tag{4}$$

$$[\mathbf{A},\mathbf{B},\mathbf{C}]\mathbf{D}=[\mathbf{D},\mathbf{B},\mathbf{C}]\mathbf{A}+[\mathbf{A},\mathbf{D},\mathbf{C}]\mathbf{B}+[\mathbf{A},\mathbf{B},\mathbf{D}]\mathbf{C} \tag{5}$$

$$[\mathbf{q},\mathbf{q}',\mathbf{q}''][\mathbf{r},\mathbf{r}',\mathbf{r}'']=\begin{vmatrix}\mathbf{q}\cdot\mathbf{r} & \mathbf{q}\cdot\mathbf{r}' & \mathbf{q}\cdot\mathbf{r}''\\ \mathbf{q}'\cdot\mathbf{r} & \mathbf{q}'\cdot\mathbf{r}' & \mathbf{q}'\cdot\mathbf{r}''\\ \mathbf{q}''\cdot\mathbf{r} & \mathbf{q}''\cdot\mathbf{r}' & \mathbf{q}''\cdot\mathbf{r}''\end{vmatrix}. \tag{6}$$

Vee

The symbol $\vee$ variously means "disjunction" (in Logic) or "join" (for a Lattice).

see also Wedge

Velocity

$$\mathbf{v}\equiv\frac{d\mathbf{r}}{dt},$$

where $\mathbf{r}$ is the Position Vector and d/dt is the derivative with respect to time. Expressed in terms of the Arc Length,

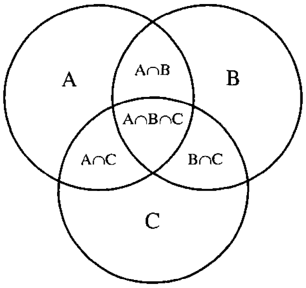
$$\mathbf{v}=\frac{ds}{dt}\hat{\mathbf{T}},$$

where $\hat{\mathbf{T}}$ is the unit Tangent Vector, so the Speed (which is the magnitude of the velocity) is

$$v\equiv|\mathbf{v}|=\frac{ds}{dt}=|\mathbf{r}'(t)|.$$

see also Angular Velocity, Position Vector, Speed

Venn Diagram



The simplest Venn diagram consists of three symmetrically placed mutually intersecting Circles. It is used in Logic theory to represent collections of sets. The region of intersection of the three Circles $A\cap B\cap C$, in the special case of the center of each being located at the intersection of the other two, is called a Reuleaux Triangle.

In general, an order n Venn diagram is a collection of n simple closed curves in the Plane such that

1. The curves partition the Plane into 2^n connected regions, and
2. Each Subset S of $\{1, 2, \ldots, n\}$ corresponds to a unique region formed by the intersection of the interiors of the curves in S (Ruskey).

Verhulst Model

see Logistic Map

Veronese Surface

A smooth 2-D surface given by embedding the Projective Plane into projective 5-space by the homogeneous parametric equations

$$v(x,y,z)=(x^2,y^2,z^2,xy,xz,yz).$$

The surface can be projected smoothly into 4-space, but all 3-D projections have singularities (Coffman). The projections of these surfaces in 3-D are called Steiner Surfaces. The Volume of the Veronese surface is $2\pi^2$.

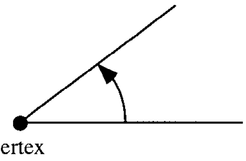
Vertex Angle



The point about which an Angle is measured is called the angle's vertex, and the angle associated with a given vertex is called the vertex angle.

see also Angle

Vertex Coloring

Brelaz's Heuristic Algorithm can be used to find a good, but not necessarily minimal, Vertex coloring of a Graph.

see also Brelaz's Heuristic Algorithm, Coloring

Vertex Connectivity

The minimum number of Vertices whose deletion from a Graph disconnects it.

see also Edge Connectivity

Vertex Cover

see Hitting Set

Vertex Degree

The degree of a Vertex of a Graph is the number of Edges which touch the Vertex, also called the Local Degree. The Vertex degree of a point A in a Graph, denoted $\rho(A)$, satisfies

$$\sum_{i=1}^{n} \rho(A_i) = 2E,$$

where E is the total number of Edges. Directed Graphs have two types of degrees, known as the Indegree and the Outdegree.

see also Directed Graph, Indegree, Local Degree, Outdegree

Vertex Enumeration

A Convex Polyhedron is defined as the set of solutions to a system of linear inequalities

$$\mathsf{m}\mathbf{x} \leq \mathbf{b},$$

where m is a Real $s \times d$ Matrix and $\mathbf{b}$ is a Real s-Vector. Given m and $\mathbf{b}$, vertex enumeration is the determination of the polyhedron's Vertices.

see also Convex Polyhedron, Polyhedron

Vertex Figure

The line joining the Midpoints of adjacent sides in a Polygon is called the polygon's vertex figure. For a regular n-gon with side length s,

$$v = s\cos\left(\frac{\pi}{n}\right).$$

For a Polyhedron, the faces that join at a Vertex form a solid angle whose section by the plane is the vertex figure.

see also Truncation

Vertex (Graph)

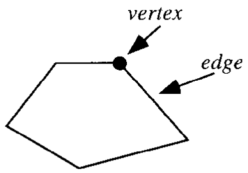
A point of a Graph, also called a Node.

see also Edge (Graph), Null Graph, Tait Coloring, Tait Cycle, Tait's Hamiltonian Graph Conjecture, Vertex (Polygon)

Vertex (Parabola)

For a Parabola oriented vertically and opening upwards, the vertex is the point where the curve reaches a minimum.

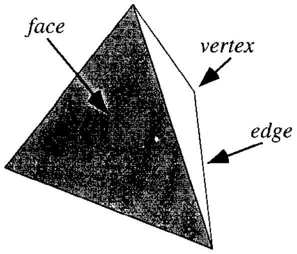
Vertex (Polygon)



A point at which two EDGES of a POLYGON meet.

see also PRINCIPAL VERTEX, VERTEX (GRAPH), VERTEX (POLYHEDRON)

Vertex (Polyhedron)



A point at which three of more EDGES of a POLYHEDRON meet. The concept can also be generalized to a POLYTOPE.

see also VERTEX (GRAPH), VERTEX (POLYGON)

Vertex (Polytope)

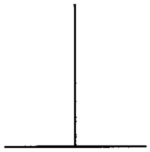
The vertex of a POLYTOPE is a point where edges of the POLYTOPE meet.

Vertical

Oriented in an up-down position.

see also HORIZONTAL

Vertical-Horizontal Illusion



The HORIZONTAL line segment in the above figure appears to be shorter than the VERTICAL line segment, despite the fact that it has the same length.

Snyder, J. P. *Map Projections—A Working Manual.* U. S. Geological Survey Professional Paper 1395. Washington, DC: U. S. Government Printing Office, pp. 173–178, 1987.

Vertical Tangent

A function $f(x)$ has a vertical tangent line at x_0 if f is continuous at x_0 and

$$\lim_{x \to x_0} f'(x) = \pm\infty.$$

Vesica Piscis

see LENS

Vibration Problem

Solution of a system of second-order homogeneous ordinary differential equations with constant COEFFICIENTS of the form

$$\frac{d^2\mathbf{x}}{dt^2} + \mathsf{B}\mathbf{x} = 0,$$

where B is a POSITIVE DEFINITE MATRIX. To solve the vibration problem,

1. Solve the CHARACTERISTIC EQUATION of B to get EIGENVALUES $\lambda_1, \ldots, \lambda_n$. Define $\omega_i \equiv \sqrt{\lambda_i}$.
2. Compute the corresponding EIGENVECTORS $\mathbf{e}_1, \ldots, \mathbf{e}_n$.
3. The normal modes of oscillation are given by $\mathbf{x}_1 = A_1 \sin(\omega_1 t + \alpha_1)\mathbf{e}_1, \ldots, \mathbf{x}_n = A_n \sin(\omega_n t + \alpha_n)\mathbf{e}_n$, where $A_1, \ldots, A_n$ and $\alpha_1, \ldots, \alpha_n$ are arbitrary constants.
4. The general solution is $\mathbf{x} = \sum_{i=1}^n \mathbf{x}_i$.

Vickery Auction

An AUCTION in which the highest bidder wins but pays only the second-highest bid. This variation over the normal bidding procedure is supposed to encourage bidders to bid the largest amount they are willing to pay.

see also AUCTION

Viergruppe

The mathematical group $Z_4 \otimes Z_4$, also denoted D_2. Its multiplication table is

V	I	V_1	V_2	V_3
I	V_1	V_2	V_3	V_4
V_1	V_1	I	V_3	V_2
V_2	V_2	V_3	I	V_1
V_3	V_3	V_2	V_1	I

Vieta's Substitution

The substitution of

$$x = w - \frac{p}{3w}$$

into the standard form CUBIC EQUATION

$$x^3 + px = q,$$

which reduces the cubic to a QUADRATIC EQUATION in w^3,

$$(w^3)^2 - \tfrac{1}{27}p^3(w^3) - q = 0.$$

see also CUBIC EQUATION

Vigesimal

The base-20 notational system for representing REAL NUMBERS. The digits used to represent numbers using vigesimal NOTATION are 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F, G, H, I, and J. A base-20 number system was used by the Aztecs and Mayans. The Mayans compiled extensive observations of planetary positions in base-20 notation.

Vinculum

A horizontal line placed above multiple quantities to indicate that they form a unit. It is most commonly used to denote ROOTS ($\sqrt{12345}$) and repeating decimals ($0.\overline{111}$).

Vinogradov's Theorem

Every sufficiently large ODD number is a sum of three PRIMES. Proved in 1937.

see also GOLDBACH CONJECTURE

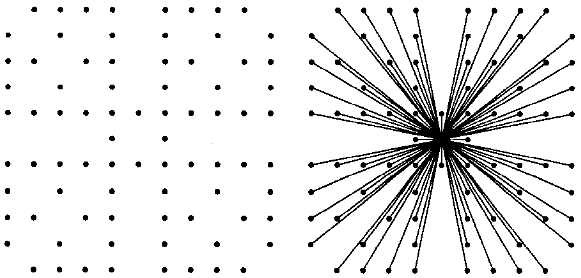
Virtual Group

see GROUPOID

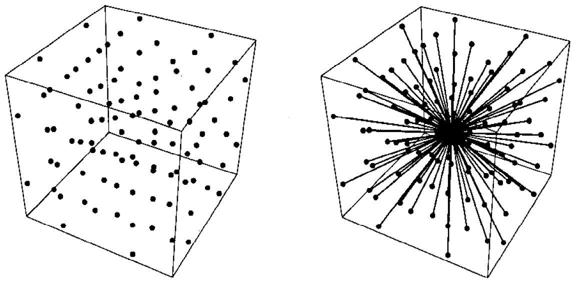
Visibility

see VISIBLE POINT

Visible Point



Two LATTICE POINTS (x, y) and (x', y') are mutually visible if the line segment joining them contains no further LATTICE POINTS. This corresponds to the requirement that $(x' - x, y' - y) = 1$, where (m, n) denotes the GREATEST COMMON DIVISOR. The plots above show the first few points visible from the ORIGIN.



If a LATTICE POINT is selected at random in 2-D, the probability that it is visible from the origin is $6/\pi^2$. This is also the probability that two INTEGERS picked at random are RELATIVELY PRIME. If a LATTICE POINT is picked at random in n-D, the probability that it is visible from the ORIGIN is $1/\zeta(n)$, where $\zeta(n)$ is the RIEMANN ZETA FUNCTION.

An invisible figure is a POLYGON all of whose corners are invisible. There are invisible sets of every finite shape. The lower left-hand corner of the invisible squares with smallest x coordinate of AREAS 2 and 3 are (14, 20) and (104, 6200).

Visible Point Vector Identity

A set of identities involving n-D visible lattice points was discovered by Campbell (1994). Examples include

$$\prod_{\substack{(a,b)=1\\ a\geq 0,b\leq 1}} (1-y^a z^b)^{-1/b} = (1-z)^{-1/(1-y)}$$

for $|yz|, |z| < 1$ and

$$\prod_{\substack{(a,b,c)=1\\ a,b\geq 0,c\leq 1}} (1-x^a y^b z^c)^{-1/c} = (1-z)^{-1/[(1-x)(1-y)]}$$

for $|xyz|, |xz|, |yz|, |z| < 1$.

Vitali's Convergence Theorem

Let $f_n(z)$ be a sequence of functions, each regular in a region D, let $|f_n(z)| \leq M$ for every n and z in D, and let $f_n(z)$ tend to a limit as $n \to \infty$ at a set of points having a LIMIT POINT inside D. Then $f_n(z)$ tends uniformly to a limit in any region bounded by a contour interior to D, the limit therefore being an analytic function of z.

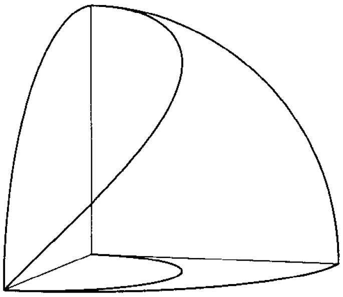
Viviani's Curve



The SPACE CURVE giving the intersection of the CYLINDER

$$(x-a)^2 + y^2 = a^2 \tag{1}$$

and the SPHERE

$$x^2 + y^2 + z^2 = 4^2. \tag{2}$$

It is given by the parametric equations

$$x = a(1+\cos t) \tag{3}$$
$$y = a\sin t \tag{4}$$
$$z = 2a\sin(\tfrac{1}{2}t). \tag{5}$$

The CURVATURE and TORSION are given by

$$\kappa(t) = \frac{\sqrt{13+3\cos t}}{a(3+\cos t)^{3/2}} \tag{6}$$
$$\tau(t) = \frac{6\cos(\frac{1}{2}t)}{a(13+3\cos t)}. \tag{7}$$

Viviani's Theorem

For a point P inside an EQUILATERAL TRIANGLE ΔABC, the sum of the perpendiculars p_i from P to the sides of the TRIANGLE is equal to the ALTITUDE h. This result is simply proved as follows,

$$\Delta ABC = \Delta PBC + \Delta PCA + \Delta PAB. \tag{1}$$

With s the side length,

$$\tfrac{1}{2}sh = \tfrac{1}{2}sp_a + \tfrac{1}{2}sp_b + \tfrac{1}{2}sp_c, \tag{2}$$

so

$$h = p_a + p_b + p_c. \tag{3}$$

see also ALTITUDE, EQUILATERAL TRIANGLE

Vojta's Conjecture

A conjecture which treats the heights of points relative to a canonical class of a curve defined over the INTEGERS.

Volume

The volume of a solid body is the amount of "space" it occupies. Volume has units of LENGTH cubed (i.e., cm^3, m^3, in^3, etc.) For example, the volume of a box (RECTANGULAR PARALLELEPIPED) of LENGTH L, WIDTH W, and HEIGHT H is given by

$$V=L\times W\times H.$$

The volume can also be computed for irregularly-shaped and curved solids such as the CYLINDER and CUBE. The volume of a SURFACE OF REVOLUTION is particularly simple to compute due to its symmetry.

The following table gives volumes for some common SURFACES. Here r denotes the RADIUS, h the height, A the base AREA, and s the SLANT HEIGHT (Beyer 1987).

Surface	V
cone	$\frac{1}{3}\pi r^2 h$
conical frustum	$\frac{1}{3}\pi h({R_1}^2+{R_2}^2+R_1R_2)$
cube	a^3
cylinder	$\pi r^2 h$
ellipsoid	$\frac{4}{3}\pi abc$
oblate spheroid	$\frac{4}{3}\pi a^2 b$
prolate spheroid	$\frac{4}{3}\pi ab^2$
pyramid	$\frac{1}{3}Ah$
pyramidal frustum	$\frac{1}{3}h(A_1+A_2+\sqrt{A_1A_2})$
sphere	$\frac{4}{3}\pi r^3$
spherical sector	$\frac{2}{3}\pi r^2 h$
spherical segment	$\frac{1}{3}\pi h^2 r(3r-h)$
torus	$2\pi^2 Rr^2$

Even simple SURFACES can display surprisingly counterintuitive properties. For instance, the SURFACE OF REVOLUTION of $y=1/x$ around the x-axis for $x\geq 1$ is called GABRIEL'S HORN, and has finite volume, but infinite SURFACE AREA.

The generalization of volume to n DIMENSIONS for $n\geq 4$ is known as CONTENT.

see also ARC LENGTH, AREA, CONTENT, HEIGHT, LENGTH (SIZE), SURFACE AREA, SURFACE OF REVOLUTION, VOLUME ELEMENT, WIDTH (SIZE)

References

Beyer, W. H. *CRC Standard Mathematical Tables, 28th ed.* Boca Raton, FL: CRC Press, pp. 127–132, 1987.

Volume Element

A volume element is the differential element dV whose VOLUME INTEGRAL over some range in a given coordinate system gives the VOLUME of a solid,

$$V=\iiint_G dx\,dy\,dz. \tag{1}$$

In $\mathbb{R}^n$, the volume of the infinitesimal n-HYPERCUBE bounded by dx_1, ..., dx_n has volume given by the WEDGE PRODUCT

$$dV=dx_1\wedge\ldots\wedge dx_n \tag{2}$$

(Gray 1993).

The use of the antisymmetric WEDGE PRODUCT instead of the symmetric product $dx_1\ldots dx_n$ is a technical refinement often omitted in informal usage. Dropping the wedges, the volume element for CURVILINEAR COORDINATES in $\mathbb{R}^3$ is given by

$$\begin{aligned} dV &= |(h_1\hat{\mathbf{u}}_1\,du_1)\cdot(h_2\hat{\mathbf{u}}_2\,du_2)\times(h_3\hat{\mathbf{u}}_3\,du_3)| && (3)\\ &= h_1h_2h_3\,du_1\,du_2\,du_3 && (4)\\ &= \left|\frac{\partial\mathbf{r}}{\partial u_1}\cdot\frac{\partial\mathbf{r}}{\partial u_2}\times\frac{\partial\mathbf{r}}{\partial u_3}\right| du_1\,du_2\,du_3 && (5)\\ &= \begin{vmatrix} \frac{\partial x}{\partial u_1} & \frac{\partial x}{\partial u_2} & \frac{\partial x}{\partial u_3}\\ \frac{\partial y}{\partial u_1} & \frac{\partial y}{\partial u_2} & \frac{\partial y}{\partial u_3}\\ \frac{\partial z}{\partial u_1} & \frac{\partial z}{\partial u_2} & \frac{\partial z}{\partial u_3} \end{vmatrix} du_1\,du_2\,du_3 && (6)\\ &= \left|\frac{\partial(x,y,z)}{\partial(u_1,u_2,u_3)}\right| du_1\,du_2\,du_3, && (7) \end{aligned}$$

where the latter is the JACOBIAN and the h_i are SCALE FACTORS.

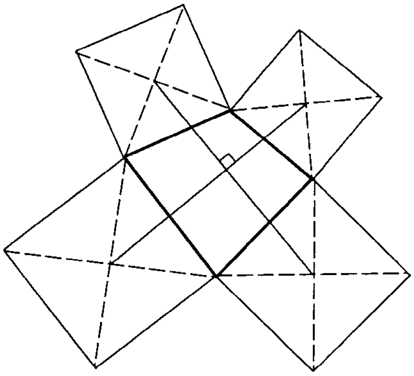
von Aubel's Theorem



Given an arbitrary QUADRILATERAL, place a SQUARE outwardly on each side, and connect the centers of opposite SQUARES. Then the two lines are of equal length and cross at a RIGHT ANGLE.

see also QUADRILATERAL, RIGHT ANGLE, SQUARE

References

Kitchen, E. "Dörrie Tiles and Related Miniatures." *Math. Mag.* **67**, 128–130, 1994.

von Dyck's Theorem

Let a GROUP G have a presentation

$$G = (x_1,\ldots,x_n | r_j(x_1,\ldots,x_n), j \in J)$$

so that $G = F/R$, where F is the FREE GROUP with basis $\{x_1,\ldots,x_n\}$ and R is the NORMAL SUBGROUP generated by the r_j. If H is a GROUP with $H = \langle y_1,\ldots,y_n\rangle$ and if $r_j(y_1,\ldots,y_n) = 1$ for all j, then there is a surjective homomorphism $G \to H$ with $x_i \mapsto y_i$ for all i.

von Staudt-Clausen Theorem

$$B_{2n} = A_n - \sum_{\substack{p_k\\ p_k-1|2n}} \frac{1}{p_k},$$

where B_{2n} is a BERNOULLI NUMBER, A_n is an INTEGER, and the p_ks are the PRIMES satisfying $p_k - 1|2k$. For example, for $k = 1$, the primes included in the sum are 2 and 3, since $(2-1)|2$ and $(3-1)|2$. Similarly, for $k = 6$, the included primes are (2, 3, 5, 7, 13), since (1, 2, 3, 6, 12) divide $12 = 2 \cdot 6$. The first few values of A_n for $n = 1, 2, \ldots$ are 1, 1, 1, 1, 1, 1, 2, -6, 56, -528, ... (Sloane's A000164).

The theorem was rediscovered by Ramanujan (Hardy 1959, p. 11) and can be proved using p-ADIC NUMBERS.

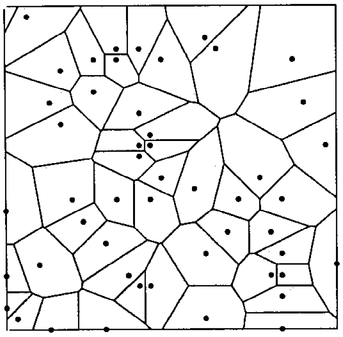
von Staudt Theorem

see VON STAUDT-CLAUSEN THEOREM

Voronoi Cell

The generalization of a VORONOI POLYGON to n-D, for $n > 2$.

Voronoi Diagram



The partitioning of a plane with n points into n convex POLYGONS such that each POLYGON contains exactly one point and every point in a given POLYGON is closer to its central point than to any other. A Voronoi diagram is sometimes also known as a DIRICHLET TESSELLATION. The cells are called DIRICHLET REGIONS, THIESSEN POLYTOPES, or VORONOI POLYGONS.

Voronoi Polygon

A POLYGON whose interior consists of all points in the plane which are closer to a particular LATTICE POINT than to any other. The generalization to n-D is called a DIRICHLET REGION, THIESSEN POLYTOPE, or VORONOI CELL.

Voting

It is possible to conduct a secret ballot even if the votes are sent in to a central polling station (Lipton and Widgerson, Honsberger 1985).

VR Number

A "visual representation" number which is a sum of some simple function of its digits. For example,

$$1233 = 12^2 + 33^2$$

$$2661653 = 1653^2 - 266^2$$

$$221859 = 22^3 + 18^3 + 59^3$$

$$40585 + 4! + 0! + 5! + 8! + 5!$$

$$148349 = !1+!4+!8+!3+!4+!9$$

$$4913 = (4 + 9 + 1 + 3)^3$$

are all VR numbers given by Madachy (1979).

Walk

A sequence of VERTICES and EDGES such that the VERTICES and EDGES are adjacent. A walk is therefore equivalent to a graph CYCLE, but with the VERTICES along the walk enumerated as well as the EDGES.

see also CIRCUIT, CYCLE (GRAPH), PATH, RANDOM WALK

Wallace-Bolyai-Gerwein Theorem

Two POLYGONS are congruent by DISSECTION IFF they have the same AREA. In particular, any POLYGON is congruent by DISSECTION to a SQUARE of the same AREA. Laczkovich (1988) also proved that a CIRCLE is congruent by DISSECTION to a SQUARE (furthermore, the DISSECTION can be accomplished using TRANSLATIONS only).

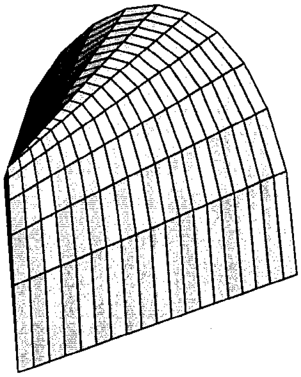
Wallis's Conical Edge



The RIGHT CONOID surface given by the parametric equations

$$\begin{aligned} x(u,v) &= v\cos u \\ y(u,v) &= v\sin u \\ z(u,v) &= c\sqrt{a^2 - b^2\cos^2 u}. \end{aligned}$$

see also RIGHT CONOID

References
Gray, A. *Modern Differential Geometry of Curves and Surfaces.* Boca Raton, FL: CRC Press, pp. 354–355, 1993.

Wallis Cosine Formula

$$\int_0^{\pi/2} \cos^n x\,dx = \begin{cases} \frac{\pi}{2}\frac{1\cdot3\cdot5\cdots(n-1)}{2\cdot4\cdot6\cdots n} & \text{for } n = 2, 4, \ldots \\ \frac{2\cdot4\cdot6\cdots(n-1)}{1\cdot3\cdot5\cdots n} & \text{for } n = 3, 5, \ldots. \end{cases}$$

see also WALLIS FORMULA, WALLIS SINE FORMULA

Wallis Formula

The Wallis formula follows from the INFINITE PRODUCT representation of the SINE

$$\sin x = x\prod_{n=1}^\infty \left(1 - \frac{x^2}{\pi^2 n^2}\right). \tag{1}$$

Taking $x = \pi/2$ gives

$$1 = \frac{\pi}{2}\prod_{n=1}^\infty \left[1 - \frac{1}{(2n)^2}\right] = \frac{\pi}{2}\prod_{n=1}^\infty \left[\frac{(2n)^2 - 1}{(2n)^2}\right], \tag{2}$$

so

$$\frac{\pi}{2} = \prod_{n=1}^\infty \left[\frac{(2n)^2}{(2n-1)(2n+1)}\right] = \frac{2\cdot2}{1\cdot3}\frac{4\cdot4}{3\cdot5}\frac{6\cdot6}{5\cdot7}\cdots. \tag{3}$$

A derivation due to Y. L. Yung uses the RIEMANN ZETA FUNCTION. Define

$$F(s) \equiv -\operatorname{Li}_s(-1) = \sum_{n=1}^{\infty} \frac{(-1)^n}{n^s}$$

$$= (1-2^{1-s})\zeta(s) \qquad (4)$$

$$F'(s) = \sum_{n=1}^{\infty} \frac{(-1)^n \ln n}{n^s}, \qquad (5)$$

so

$$F'(0) = \sum_{n=1}^{\infty} (-1)^n \ln n = -\ln 1 + \ln 2 - \ln 3 + \ldots$$

$$= \ln\left(\frac{2\cdot 4\cdot 6\cdots}{1\cdot 3\cdot 5\cdots}\right). \qquad (6)$$

Taking the derivative of the zeta function expression gives

$$\frac{d}{ds}(1-2^{1-s})\zeta(s) = 2^{1-s}(\ln 2)\zeta(s) + (1-2^{1-s})\zeta'(s) \quad (7)$$

$$\left[\frac{d}{ds}(1-2^{1-s})\zeta(s)\right]_{s=0} = -\ln 2 - \zeta'(0)$$

$$= -\ln 2 + \tfrac{1}{2}\ln(2\pi) = \ln\left(\frac{\sqrt{2\pi}}{2}\right) = \ln\left(\sqrt{\frac{\pi}{2}}\right). \quad (8)$$

Equating and squaring then gives the Wallis formula, which can also be expressed

$$\frac{\pi}{2} = \left[4^{\zeta(0)} e^{-\zeta'(0)}\right]^2. \qquad (9)$$

The q-ANALOG of the Wallis formula for $q = 2$ is

$$\prod_{k=1}^{\infty} (1-q^{-k})^{-1} = 3.4627466194\ldots \qquad (10)$$

(Finch).

Walsh Function

Functions consisting of a number of fixed-amplitude square pulses interposed with zeros. Following Harmuth (1969), designate those with EVEN symmetry $\operatorname{Cal}(k, t)$ and those with ODD symmetry $\operatorname{Sal}(k, t)$. Define the SEQUENCY k as half the number of zero crossings in the time base. Walsh functions with nonidentical SEQUENCIES are ORTHOGONAL, as are the functions $\operatorname{Cal}(k, t)$ and $\operatorname{Sal}(k, t)$. The product of two Walsh functions is also a Walsh function. The Walsh functions

$$\operatorname{Wal}(k, t) = \begin{cases} \operatorname{Cal}(k/2, t) & \text{for } k = 0,\ 2,\ 4,\ \ldots \\ \operatorname{Sal}((k+1)/2, t) & \text{for } k = 1,\ 3,\ 5,\ \ldots. \end{cases}$$

The Walsh functions $\operatorname{Cal}(k, t)$ for $k = 0, 1, \ldots, n/2 - 1$ and $\operatorname{Sal}(k, t)$ for $k = 1, 2, \ldots, n/2$ are given by the rows of the HADAMARD MATRIX H_n.

Wang's Conjecture

Wang's conjecture states that if a set of tiles can tile the plane, then they can always be arranged to do so periodically (Wang 1961). The CONJECTURE was refuted when Berger (1966) showed that an aperiodic set of tiles existed. Berger used 20,426 tiles, but the number has subsequently been greatly reduced.

Ward's Primality Test

Let N be an ODD INTEGER, and assume there exists a LUCAS SEQUENCE $\{U_n\}$ with associated SYLVESTER CYCLOTOMIC NUMBERS $\{Q_n\}$ such that there is an $n > \sqrt{N}$ (with n and N RELATIVELY PRIME) for which N DIVIDES Q_n. Then N is a PRIME unless it has one of the following two forms:

1. $N = (n-1)^2$, with $n-1$ PRIME and $n > 4$, or
2. $N = n^2 - 1$, with $n-1$ and $n+1$ PRIME.

Waring's Conjecture

see WARING'S PRIME CONJECTURE, WARING'S SUM CONJECTURE

Waring Formula

$$A^n + B^n = \sum_{j=0}^{\lfloor n/2 \rfloor} (-1)^j \frac{n}{n-j} \binom{n-j}{j} (AB)^j (A+B)^{n-2j},$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION and $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

see also FERMAT'S LAST THEOREM

Waring's Prime Conjecture

Every ODD INTEGER is a PRIME or the sum of three PRIMES.

Waring's Problem

Waring proposed a generalization of LAGRANGE'S FOUR-SQUARE THEOREM, stating that every RATIONAL INTEGER is the sum of a fixed number $g(n)$ of nth POWERS of INTEGERS, where n is any given POSITIVE INTEGER and $g(n)$ depends only on n. Waring originally speculated that $g(2) = 4$, $g(3) = 9$, and $g(4) = 19$. In 1909, Hilbert proved the general conjecture using an identity in 25-fold multiple integrals (Rademacher and Toeplitz 1957, pp. 52–61).

In LAGRANGE'S FOUR-SQUARE THEOREM, Lagrange proved that $g(2) = 4$, where 4 may be reduced to 3 except for numbers of the form $4^n(8k+7)$ (as proved by Legendre). In the early twentieth century, Dickson, Pillai, and Niven proved that $g(3) = 9$. Hilbert, Hardy, and Vinogradov proved $g(4) \leq 21$, and this was subsequently reduced to $g(4) = 19$ by Balasubramanian *et al.* (1986). Liouville proved (using LAGRANGE'S FOUR-SQUARE THEOREM and LIOUVILLE POLYNOMIAL IDENTITY) that $g(5) \leq 53$, and this was improved to 47, 45, 41, 39, 38, and finally $g(5) \leq 37$ by Wieferich. See Rademacher and Toeplitz (1957, p. 56) for a simple proof. J.-J. Chen (1964) proved that $g(5) = 37$.

Dickson, Pillai, and Niven also conjectured an explicit formula for $g(s)$ for $s > 6$ (Bell 1945), based on the relationship

$$\left(\frac{3}{2}\right)^n - \left\lfloor \left(\frac{3}{2}\right)^n \right\rfloor = 1 - \left(\frac{1}{2}\right)^n \left\{ \left\lfloor \left(\frac{3}{2}\right)^n + 2 \right\rfloor \right\}. \quad (1)$$

If the DIOPHANTINE (i.e., n is restricted to being an INTEGER) inequality

$$\left\{\left(\frac{3}{2}\right)^n\right\} \le 1 - \left(\frac{3}{4}\right)^n \tag{2}$$

is true, then

$$g(n) = 2^n + \left\lfloor\left(\frac{3}{2}\right)^n\right\rfloor - 2. \tag{3}$$

This was given as a lower bound by Euler, and has been verified to be correct for $6 \le n \le 200,000$. Since 1957, it has been known that at most a FINITE number of k exceed Euler's lower bound.

There is also a related problem of finding the least INTEGER n such that every POSITIVE INTEGER beyond a certain point (i.e., all but a FINITE number) is the SUM of $G(n)$ nth POWERS. From 1920–1928, Hardy and Littlewood showed that

$$G(n) \le (n-2)2^{n-1} + 5 \tag{4}$$

and conjectured that

$$G(k) < \begin{cases} 2k+1 & \text{for } k \text{ not a power of 2} \\ 4k & \text{for } k \text{ a power of 2.} \end{cases} \tag{5}$$

The best currently known bound is

$$G(k) < ck \ln k \tag{6}$$

for some constant c. Heilbronn (1936) improved Vinogradov's results to obtain

$$G(n) \le 6n \ln n + \left[4 + 3 \ln\left(3 + \frac{2}{n}\right)\right] n + 3. \tag{7}$$

It has long been known that $G(2) = 4$. Dickson and Landau proved that the only INTEGERS requiring nine CUBES are 23 and 239, thus establishing $G(3) \le 8$. Wieferich proved that only 15 INTEGERS require eight CUBES: 15, 22, 50, 114, 167, 175, 186, 212, 213, 238, 303, 364, 420, 428, and 454, establishing $G(3) \le 7$. The largest number known requiring seven CUBES is 8042. In 1933, Hardy and Littlewood showed that $G(4) \le 19$, but this was improved in 1936 to 16 or 17, and shown to be exactly 16 by Davenport (1939b). Vaughan (1986) greatly improved on the method of Hardy and Littlewood, obtaining improved results for $n \ge 5$. These results were then further improved by Brüdern (1990), who gave $G(5) \le 18$, and Wooley (1992), who gave $G(n)$ for $n = 6$ to 20. Vaughan and Wooley (1993) showed $G(8) \le 42$.

Let $G^+(n)$ denote the smallest number such that *almost all* sufficiently large INTEGERS are the sum of $G^+(n)$ nth POWERS. Then $G^+(3) = 4$ (Davenport 1939a), $G^+(4) = 15$ (Hardy and Littlewood 1925), $G^+(8) = 32$ (Vaughan 1986), and $G^+(16) = 64$ (Wooley 1992). If the negatives of POWERS are permitted in addition to the powers themselves, the largest number of nth POWERS needed to represent an aribtrary integer are denoted $eg(n)$ and $EG(n)$ (Wright 1934, Hunter 1941, Gardner 1986). In general, these values are much harder to calculate than are $g(n)$ and $G(n)$.

The following table gives $g(n)$, $G(n)$, $G^+(n)$, $eg(n)$, and $EG(n)$ for $n \le 20$. The sequence of $g(n)$ is Sloane's A002804.

n	$g(n)$	$G(n)$	$G^+(n)$	$eg(n)$	$EG(n)$

Waring's Sum Conjecture

see WARING'S PROBLEM

Waring's Theorem

If each of two curves meets the LINE AT INFINITY in distinct, nonsingular points, and if all their intersections are finite, then if to each common point there is attached a weight equal to the number of intersections absorbed therein, the CENTER OF MASS of these points is the center of gravity of the intersections of the asymptotes.

Watchman Theorem

see ART GALLERY THEOREM

Watson's Formula

Let $J_\nu(z)$ be a BESSEL FUNCTION OF THE FIRST KIND, $Y_\nu(z)$ a BESSEL FUNCTION OF THE SECOND KIND, and $K_\nu(z)$ a MODIFIED BESSEL FUNCTION OF THE FIRST KIND. Also let $\Re[z] > 0$ and require $\Re[\mu - \nu] < 1$. Then

$$\begin{aligned} J_\mu(z)Y_\nu(z) - J_\nu(z)Y_\mu(z) \\ = \frac{4\sin[(\mu-\nu)\pi]}{\pi^2} \int_0^\infty K_{\nu-\mu}(2z\sinh t)e^{-(\mu+\nu)t}\,dt. \end{aligned}$$

The fourth edition of Gradshteyn and Ryzhik (1979), Iyanaga and Kawada (1980), and Ito (1987) erroneously give the exponential with a PLUS SIGN. A related integral is given by

$$\begin{aligned} J_\nu(z)\frac{\partial Y_\nu(z)}{\partial \nu} - Y_\nu(z)\frac{\partial J_\nu(z)}{\partial \nu} \\ = -\frac{4}{\pi}\int_0^\infty K_0(2z\sinh t)e^{-2\nu t}\,dt \end{aligned}$$

for $\Re[z] > 0$.

Watson-Nicholson Formula

Let $H_\nu^{(\iota)}$ be a HANKEL FUNCTION OF THE FIRST or SECOND KIND, let $x, \nu > 0$, and define

$$w = \sqrt{\left(\frac{x}{\nu}\right)^2 - 1}.$$

Then

$$\begin{aligned} H_\nu^{(\iota)}(x) = 3^{-1/2} w \exp\{(-1)^{\iota+1} i[\pi/6 + \nu(w - \tfrac{1}{3}w^3 \\ - \tan^{-1} w)]\} H_{1/3}^{(\iota)}(\tfrac{1}{3}\nu w) + \mathcal{O}|\nu^{-1}|. \end{aligned}$$

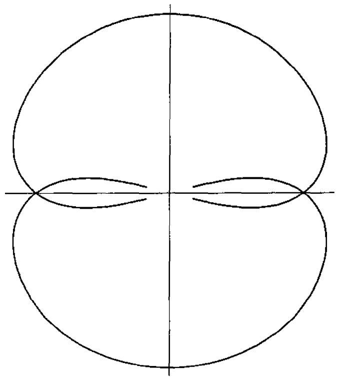
Watson's Theorem

$$\begin{aligned} {}_3F_2\left[\begin{matrix} a, b, c \\ \frac{1}{2}(a+b+1), c \end{matrix}\right] \\ = \frac{\Gamma(\frac{1}{2})\Gamma(\frac{1}{2}+c)\Gamma[\frac{1}{2}(1+a+b)]\Gamma(\frac{1}{2}-\frac{1}{2}a-\frac{1}{2}b+c)}{\Gamma[\frac{1}{2}(1+a)]\Gamma[\frac{1}{2}(1+b)]\Gamma(\frac{1}{2}-\frac{1}{2}a+c)\Gamma(\frac{1}{2}-\frac{1}{2}b+c)}, \end{aligned}$$

where ${}_3F_2(a, b, c; d, e; z)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION and $\Gamma(z)$ is the GAMMA FUNCTION.

Watt's Curve



A curve named after James Watt (1736–1819), the Scottish engineer who developed the steam engine (MacTutor Archive). The curve is produced by a LINKAGE of rods connecting two wheels of equal diameter. Let the two wheels have RADIUS b and let their centers be located a distance $2a$ apart. Further suppose that a rod of length $2c$ is fixed at each end to the CIRCUMFERENCE of the two wheels. Let P be the MIDPOINT of the rod. Then Watt's curve C is the LOCUS of P.

The POLAR equation of Watt's curve is

$$r^2 = b^2 - (a\sin\theta \pm \sqrt{c^2 - a^2\cos^2\theta}\,)^2.$$

If $a = c$, then C is a CIRCLE of RADIUS b with a figure of eight inside it.

Wave Equation

The wave equation is

$$\nabla^2\psi = \frac{1}{v^2}\frac{\partial^2\psi}{\partial t^2}, \tag{1}$$

where ∇^2 is the LAPLACIAN.

The 1-D wave equation is

$$\frac{\partial^2\psi}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2\psi}{\partial t^2}. \tag{2}$$

In order to specify a wave, the equation is subject to boundary conditions

$$\psi(0,t) = 0 \tag{3}$$

$$\psi(L,t) = 0, \tag{4}$$

and initial conditions

$$\psi(x,0) = f(x) \tag{5}$$

$$\frac{\partial\psi}{\partial t}(x,0) = g(x). \tag{6}$$

The wave equation can be solved using the so-called d'Alembert's solution, a FOURIER TRANSFORM method, or SEPARATION OF VARIABLES.

d'Alembert devised his solution in 1746, and Euler subsequently expanded the method in 1748. Let

$$\xi \equiv x - at \tag{7}$$

$$\eta \equiv x + at. \tag{8}$$

By the CHAIN RULE,

$$\frac{\partial^2\psi}{\partial x^2} = \frac{\partial^2\psi}{\partial\xi^2} + 2\frac{\partial^2\psi}{\partial\xi\partial\eta} + \frac{\partial 2\psi}{\partial\eta^2} \tag{9}$$

$$\frac{1}{v^2}\frac{\partial^2\psi}{\partial t^2} = \frac{\partial^2\psi}{\partial\xi^2} - 2\frac{\partial^2\psi}{\partial\xi\partial\eta} + \frac{\partial^2\psi}{\partial\eta^2}. \tag{10}$$

The wave equation then becomes

$$\frac{\partial^2\psi}{\partial\xi\partial\eta} = 0. \tag{11}$$

Any solution of this equation is of the form

$$\psi(\xi,\eta) = f(\eta) + g(\xi) = f(x+vt) + g(x-vt), \tag{12}$$

where f and g are *any* functions. They represent two waveforms traveling in opposite directions, f in the NEGATIVE x direction and g in the POSITIVE x direction.

The 1-D wave equation can also be solved by applying a FOURIER TRANSFORM to each side,

$$\int_{-\infty}^{\infty}\frac{\partial^2\psi(x,t)}{\partial x^2}e^{-2\pi ikx}\,dx = \frac{1}{v^2}\int_{-\infty}^{\infty}\frac{\partial^2\psi(x,t)}{\partial t^2}e^{-2\pi ikx}\,dx, \tag{13}$$

which is given, with the help of the FOURIER TRANSFORM DERIVATIVE identity, by

$$(2\pi ik)^2\Psi(k,t) = \frac{1}{v^2}\frac{\partial^2\Psi(k,t)}{\partial t^2}, \tag{14}$$

where

$$\Psi(k,t) \equiv \mathcal{F}[\psi(x,t)] = \int_{-\infty}^{\infty}\psi(x,t)e^{-2\pi ikx}\,dx. \tag{15}$$

This has solution

$$\Psi(k,t) = A(k)e^{2\pi ikvt} + B(k)e^{-2\pi ikvt}. \tag{16}$$

Taking the inverse FOURIER TRANSFORM gives

$$\begin{aligned}\psi(x,t) &\equiv \int_{-\infty}^{\infty} \Psi(k,t)e^{2\pi ikx}\,dx \\ &= \int_{-\infty}^{\infty} [A(k)e^{2\pi ikvt} \\ &\quad + B(k)e^{-2\pi ikvt}]e^{-2\pi ikx}\,dk \\ &= \int_{-\infty}^{\infty} A(k)e^{-2\pi ik(x-vt)}\,dk \\ &\quad + \int_{-\infty}^{\infty} B(k)e^{-2\pi ik(x+vt)}\,dk \\ &= f_1(x-vt) + b(k)f_2(x+vt),\end{aligned} \tag{17}$$

where

$$f_1(u) \equiv \mathcal{F}[A(k)] = \int_{-\infty}^{\infty} A(k)e^{-2\pi iku}\,dk \tag{18}$$

$$f_2(u) \equiv \mathcal{F}[B(k)] = \int_{-\infty}^{\infty} B(k)e^{-2\pi iku}\,dk. \tag{19}$$

This solution is still subject to all other initial and boundary conditions.

The 1-D wave equation can be solved by SEPARATION OF VARIABLES using a trial solution

$$\psi(x,t) = X(x)T(t). \tag{20}$$

This gives

$$T\frac{d^2X}{dx^2} = \frac{1}{v^2}X\frac{d^2T}{dt^2} \tag{21}$$

$$\frac{1}{X}\frac{d^2X}{dx^2} = \frac{1}{v^2}\frac{1}{T}\frac{d^2T}{dt^2} = -k^2. \tag{22}$$

So the solution for X is

$$X(x) = C\cos(kx) + D\sin(kx). \tag{23}$$

Rewriting (22) gives

$$\frac{1}{T}\frac{d^2T}{dt^2} = -v^2k^2 \equiv -\omega^2, \tag{24}$$

so the solution for T is

$$T(t) = E\cos(\omega t) + F\sin(\omega t), \tag{25}$$

where $v \equiv \omega/k$. Applying the boundary conditions $\psi(0,t) = \psi(L,t) = 0$ to (23) gives

$$C = 0 \qquad kL = m\pi, \tag{26}$$

where m is an INTEGER. Plugging (23), (25) and (26) back in for ψ in (21) gives, for a particular value of m,

$$\begin{aligned}\psi_m(x,t) &= [E_m\sin(\omega_m t) + F_m\cos(\omega_m t)]D_m\sin\left(\frac{m\pi x}{L}\right) \\ &\equiv [A_m\cos(\omega_m t) + B_m\sin(\omega_m t)]\sin\left(\frac{m\pi x}{L}\right).\end{aligned} \tag{27}$$

The initial condition $\dot\psi(x,0) = 0$ then gives $B_m = 0$, so (27) becomes

$$\psi_m(x,t) = A_m\cos(\omega_m t)\sin\left(\frac{m\pi x}{L}\right). \tag{28}$$

The general solution is a sum over all possible values of m, so

$$\psi(x,t) = \sum_{m=1}^{\infty} A_m\cos(\omega_m t)\sin\left(\frac{m\pi x}{L}\right). \tag{29}$$

Using ORTHOGONALITY of sines again,

$$\int_0^L \sin\left(\frac{l\pi x}{L}\right)\sin\left(\frac{m\pi x}{L}\right)dx = \tfrac{1}{2}L\delta_{lm}, \tag{30}$$

where δ_{lm} is the KRONECKER DELTA defined by

$$\delta_{mn} \equiv \begin{cases}1 & m = n \\ 0 & m \neq n\end{cases}, \tag{31}$$

gives

$$\begin{aligned}\int_0^L &\psi(x,0)\sin\left(\frac{m\pi x}{L}\right)dx \\ &= \sum_{l=1}^{\infty} A_l\sin\left(\frac{l\pi x}{L}\right)\sin\left(\frac{m\pi x}{L}\right)dx \\ &\qquad = \sum_{l=1}^{\infty} A_l\tfrac{1}{2}L\delta_{lm} = \tfrac{1}{2}LA_m,\end{aligned} \tag{32}$$

so we have

$$A_m = \frac{2}{L}\int_0^L \psi(x,0)\sin\left(\frac{m\pi x}{L}\right)dx. \tag{33}$$

The computation of A_ms for specific initial distortions is derived in the FOURIER SINE SERIES section. We already have found that $B_m = 0$, so the equation of motion for the string (29), with

$$\omega_m \equiv vk_m = \frac{vm\pi}{L}, \tag{34}$$

is

$$\psi(x,t) = \sum_{m=1}^{\infty} A_m\cos\left(\frac{vm\pi t}{L}\right)\sin\left(\frac{m\pi x}{L}\right), \tag{35}$$

where the A_m COEFFICIENTS are given by (33).

A damped 1-D wave

$$\frac{\partial^2\psi}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2\psi}{\partial t^2} + b\frac{\partial\psi}{\partial t}, \tag{36}$$

given boundary conditions

$$\psi(0,t) = 0 \tag{37}$$

$$\psi(L,t) = 0, \tag{38}$$

initial conditions

$$\psi(x,0) = f(x) \tag{39}$$

$$\frac{\partial\psi}{\partial t}(x,0) = g(x), \tag{40}$$

and the additional constraint

$$0 < b < \frac{2\pi}{Lv}, \tag{41}$$

can also be solved as a FOURIER SERIES.

$$\psi(x,t) = \sum_{n=1}^{\infty} \sin\left(\frac{n\pi x}{L}\right) e^{-v^2bt/2}[a_n \sin(\mu_n t) + b_n \cos(\mu_n t)], \tag{42}$$

where

$$\mu_n \equiv \frac{\sqrt{4v^2n^2\pi^2 - b^2L^2v^4}}{2L} = \frac{v\sqrt{4n^2\pi^2 - b^2L^2v^2}}{2L} \tag{43}$$

$$b_n = \frac{2}{L}\int_0^L \sin\left(\frac{n\pi x}{L}\right) f(x)\,dx \tag{44}$$

$$a_n = \frac{2}{L\mu_n}\left\{\int_0^L \sin\left(\frac{n\pi x}{L}\right)\left[g(x) + \frac{v^2b}{2}f(x)\right]\right\} dx. \tag{45}$$

To find the motion of a rectangular membrane with sides of length L_x and L_y (in the absence of gravity), use the 2-D wave equation

$$\frac{\partial^2 z}{\partial x^2} + \frac{\partial^2 z}{\partial y^2} = \frac{1}{v^2}\frac{\partial^2 z}{\partial t^2}, \tag{46}$$

where $z(x,y,t)$ is the vertical displacement of a point on the membrane at position (x,y) and time t. Use SEPARATION OF VARIABLES to look for solutions of the form

$$z(x,y,t) = X(x)Y(y)T(t). \tag{47}$$

Plugging (47) into (46) gives

$$YT\frac{d^2X}{dx^2} + XT\frac{d^2Y}{dy^2} = \frac{1}{v^2}XY\frac{d^2T}{dt^2}, \tag{48}$$

where the partial derivatives have now become complete derivatives. Multiplying (48) by v^2/XYT gives

$$\frac{v^2}{X}\frac{d^2X}{dx^2} + \frac{v^2}{Y}\frac{d^2Y}{dy^2} = \frac{1}{T}\frac{d^2T}{dt^2}. \tag{49}$$

The left and right sides must both be equal to a constant, so we can separate the equation by writing the right side as

$$\frac{1}{T}\frac{d^2T}{dt^2} = -\omega^2. \tag{50}$$

This has solution

$$T(t) = C_\omega \cos(\omega t) + D_\omega \sin(\omega t). \tag{51}$$

Plugging (50) back into (49),

$$\frac{v^2}{X}\frac{d^2X}{dx^2} + \frac{v^2}{Y}\frac{d^2Y}{dy^2} = -\omega^2, \tag{52}$$

which we can rewrite as

$$\frac{1}{X}\frac{d^2X}{dx^2} = -\frac{1}{Y}\frac{d^2Y}{dy^2} - \frac{\omega^2}{v^2} = -{k_x}^2 \tag{53}$$

since the left and right sides again must both be equal to a constant. We can now separate out the $Y(y)$ equation

$$\frac{1}{Y}\frac{d^2Y}{dy^2} = {k_x}^2 - \frac{\omega^2}{v^2} \equiv -{k_y}^2, \tag{54}$$

where we have defined a new constant k_y satisfying

$${k_x}^2 + {k_y}^2 = \frac{\omega^2}{v^2}. \tag{55}$$

Equations (53) and (54) have solutions

$$X(x) = E\cos(k_x x) + F\sin(k_x x) \tag{56}$$

$$Y(y) = G\cos(k_y y) + H\sin(k_y y). \tag{57}$$

We now apply the boundary conditions to (56) and (57). The conditions $z(0,y,t) = 0$ and $z(x,0,t) = 0$ mean that

$$E = 0 \qquad G = 0. \tag{58}$$

Similarly, the conditions $z(L_x,y,t) = 0$ and $z(x,L_y,t) = 0$ give $\sin(k_xL_x) = 0$ and $\sin(k_yL_y) = 0$, so $L_xk_x = p\pi$ and $L_yk_y = q\pi$, where p and q are INTEGERS. Solving for the allowed values of k_x and k_y then gives

$$k_x = \frac{p\pi}{L_x} \qquad k_y = \frac{q\pi}{L_y}. \tag{59}$$

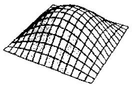
Plugging (52), (56), (57), (58), and (59) back into (22) gives the solution for particular values of p and q,

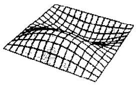
$$z_{pq}(x,y,t) = [C_\omega \cos(\omega t) + D_\omega \sin(\omega t)] \times \left[F_p \sin\left(\frac{p\pi x}{L_x}\right)\right]\left[H_q \sin\left(\frac{q\pi y}{L_y}\right)\right]. \tag{60}$$

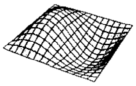
Lumping the constants together by writing $A_{pq} \equiv C_\omega F_p H_q$ (we can do this since ω is a function of p and q, so C_ω can be written as C_{pq}) and $B_{pq} \equiv D_\omega F_p H_q$, we obtain

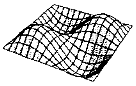
$$z_{pq}(x,y,t) = [A_{pq}\cos(\omega_{pq}t) + B_{pq}\sin(\omega_{pq}t)] \times \sin\left(\frac{p\pi x}{L_x}\right)\sin\left(\frac{q\pi y}{L_y}\right). \quad (61)$$

Plots of the spatial part for modes (1, 1), (1, 2), (2, 1), and (2, 2) follow.









The general solution is a sum over all possible values of p and q, so the final solution is

$$z(x,y,t) = \sum_{p=1}^{\infty}\sum_{q=1}^{\infty}[A_{pq}\cos(\omega_{pq}t) + B_{pq}\sin(\omega_{pq}t)] \times \sin\left(\frac{p\pi x}{L_x}\right)\sin\left(\frac{q\pi y}{L_y}\right), \quad (62)$$

where ω is defined by combining (55) and (59) to yield

$$\omega_{pq} \equiv \pi v\sqrt{\left(\frac{p}{L_x}\right)^2 + \left(\frac{q}{L_y}\right)^2}. \quad (63)$$

Given the initial conditions $z(x,y,0)$ and $\frac{\partial z}{\partial t}(x,y,0)$, we can compute the A_{pq}s and B_{pq}s explicitly. To accomplish this, we make use of the orthogonality of the SINE function in the form

$$I \equiv \int_0^L \sin\left(\frac{m\pi x}{L}\right)\sin\left(\frac{n\pi x}{L}\right)dx = \tfrac{1}{2}L\delta_{mn}, \quad (64)$$

where δ_{mn} is the KRONECKER DELTA. This can be demonstrated by direct INTEGRATION. Let $u \equiv \pi x/L$ so $du = (\pi/L)\,dx$ in (64), then

$$I = \frac{L}{\pi}\int_0^\pi \sin(mu)\sin(nu)\,du. \quad (65)$$

Now use the trigonometric identity

$$\sin\alpha\sin\beta = \tfrac{1}{2}[\cos(\alpha-\beta) - \cos(\alpha+\beta)] \quad (66)$$

to write

$$I = \frac{L}{2\pi}\int_0^\pi \cos[(m-n)u]\,du + \int_0^\pi \cos[(m+n)u]\,du. \quad (67)$$

Note that for an INTEGER $l \neq 0$, the following INTEGRAL vanishes

$$\int_0^\pi \cos(lu)\,du = \frac{1}{l}[\sin(lu)]_0^\pi = \frac{1}{l}[\sin(l\pi) - \sin 0] = \frac{1}{l}\sin(l\pi) = 0, \quad (68)$$

since $\sin(l\pi) = 0$ when l is an INTEGER. Therefore, $I = 0$ when $l \equiv m - n \neq 0$. However, I does *not* vanish when $l = 0$, since

$$\int_0^\pi \cos(0\cdot u)\,du = \int_0^\pi du = \pi. \quad (69)$$

We therefore have that $I = L\delta_{mn}/2$, so we have derived (64). Now we multiply $z(x,y,0)$ by two sine terms and integrate between 0 and L_x and between 0 and L_y,

$$I = \int_0^{L_y}\left[\int_0^{L_x} z(x,y,0)\sin\left(\frac{p\pi x}{L_x}\right)dx\right] \times \sin\left(\frac{q\pi y}{L_y}\right)dy. \quad (70)$$

Now plug in $z(x,y,t)$, set $t = 0$, and prime the indices to distinguish them from the p and q in (70),

$$I = \sum_{q'=1}^{\infty}\int_0^{L_y}\left[\sum_{p'=1}^{\infty}A_{p'q'}\int_0^{L_x}\sin\left(\frac{p\pi x}{L_x}\right)\sin\left(\frac{p'\pi x}{L_x}\right)dx\right] \times \sin\left(\frac{q\pi y}{L_y}\right)\sin\left(\frac{q'\pi y}{L_y}\right)dy. \quad (71)$$

Making use of (64) in (71),

$$I = \sum_{q'=1}^{\infty}\int_0^{L_y}\sum_{p'=1}^{\infty}A_{p'q'}\frac{L_x}{2}\delta_{p,p'} \times \sin\left(\frac{q\pi y}{L_y}\right)\sin\left(\frac{q'\pi y}{L_y}\right)dy, \quad (72)$$

so the sums over p' and q' collapse to a single term

$$I = \frac{L_x}{2}\sum_{q=1}^{\infty}A_{pq'}\frac{L_y}{2}\delta_{q,q'} = \frac{L_xL_y}{4}A_{pq}. \quad (73)$$

Equating (72) and (73) and solving for A_{pq} then gives

$$A_{pq} = \frac{4}{L_xL_y}\int_0^{L_y}\left[\int_0^{L_x} z(x,y,0)\sin\left(\frac{p\pi x}{L_x}\right)dx\right] \times \sin\left(\frac{q\pi y}{L_y}\right)dy. \quad (74)$$

An analogous derivation gives the B_{pq}s as

$$B_{pq} = \frac{4}{\omega_{pq} L_x L_y} \int_0^{L_y} \left[\int_0^{L_x} \frac{\partial z}{\partial t}(x,y,0) \sin\left(\frac{p\pi x}{L_x}\right) dx \right] \times \sin\left(\frac{q\pi y}{L_y}\right) dy. \quad (75)$$

The equation of motion for a membrane shaped as a RIGHT ISOSCELES TRIANGLE of length c on a side and with the sides oriented along the POSITIVE x and y axes is given by

$$\psi(x,y,t) = [C_{pq}\cos(\omega_{pq}t) + D_{pq}\sin(\omega_{pq}t)] \times \left[\sin\left(\frac{p\pi x}{c}\right)\sin\left(\frac{q\pi y}{c}\right) - \sin\left(\frac{q\pi x}{c}\right)\sin\left(\frac{p\pi y}{c}\right)\right], \quad (76)$$

where

$$\omega_{pq} = \frac{\pi v}{c}\sqrt{p^2+q^2} \quad (77)$$

and p, q INTEGERS with $p > q$. This solution can be obtained by subtracting two wave solutions for a square membrane with the indices reversed. Since points on the diagonal which are equidistant from the center must have the same wave equation solution (by symmetry), this procedure gives a wavefunction which will vanish along the diagonal *as long as* p *and* q *are both* EVEN *or* ODD. We must further restrict the modes since those with $p < q$ give wavefunctions which are just the NEGATIVE of (q,p) and (p,p) give an identically zero wavefunction. The following plots show (3, 1), (4, 2), (5, 1), and (5,3).

Wave Operator

An OPERATOR relating the asymptotic state of a DYNAMICAL SYSTEM governed by the Schrödinger equation

$$i\frac{d}{dt}\psi(t) = H\psi(t)$$

to its original asymptotic state.

see also SCATTERING OPERATOR

Wave Surface

A SURFACE represented parametrically by ELLIPTIC FUNCTIONS.

Wavelet

Wavelets are a class of a functions used to localize a given function in both space and scaling. A family of wavelets can be constructed from a function $\psi(x)$, sometimes known as a "mother wavelet," which is confined in a finite interval. "Daughter wavelets" $\psi^{a,b}(x)$ are then formed by translation (b) and contraction (a). Wavelets are especially useful for compressing image data, since a WAVELET TRANSFORM has properties which are in some ways superior to a conventional FOURIER TRANSFORM.

An individual wavelet can be defined by

$$\psi^{a,b}(x) = |a|^{-1/2}\psi\left(\frac{x-b}{a}\right). \quad (1)$$

Then

$$W_\psi(f)(a,b) = \frac{1}{\sqrt{a}}\int_{-\infty}^{\infty} f(t)\psi\left(\frac{t-b}{a}\right) dt, \quad (2)$$

and CALDERÓN'S FORMULA gives

$$f(x) = C_\psi \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \left\langle f, \psi^{a,b}\right\rangle \psi^{a,b}(x) a^{-2}\, da\, db. \quad (3)$$

A common type of wavelet is defined using HAAR FUNCTIONS.

Wavelet Matrix

A MATRIX composed of HAAR FUNCTIONS which is used in the WAVELET TRANSFORM. The fourth-order wavelet matrix is given by

$$\begin{aligned} W_4 &= \begin{bmatrix} 1 & 1 & 1 & 0 \\ 1 & 1 & -1 & 0 \\ 1 & -1 & 0 & 1 \\ 1 & -1 & 0 & -1 \end{bmatrix} \\ &= \begin{bmatrix} 1 & 1 & & \\ 1 & -1 & & \\ & & 1 & 1 \\ & & 1 & -1 \end{bmatrix} \begin{bmatrix} 1 & & & \\ & & 1 & \\ & 1 & & \\ & & & 0 \end{bmatrix} \\ &\quad \times \begin{bmatrix} 1 & 1 & & \\ 1 & -1 & & \\ & & 1 & \\ & & & 1 \end{bmatrix}. \end{aligned}$$

A wavelet matrix can be computed in $\mathcal{O}(n)$ steps, compared to $\mathcal{O}(n \lg 2)$ for the FOURIER MATRIX.

see also FOURIER MATRIX, WAVELET, WAVELET TRANSFORM

Wavelet Transform

A transform which localizes a function both in space and scaling and has some desirable properties compared to the FOURIER TRANSFORM. The transform is based on a WAVELET MATRIX, which can be computed more quickly than the analogous FOURIER MATRIX.

Weak Convergence

Weak convergence is usually either denoted $x_n \overset{w}{\to} x$ or $x_n \rightharpoonup x$. A SEQUENCE $\{x_n\}$ of VECTORS in an INNER PRODUCT SPACE E is called weakly convergent to a VECTOR in E if

$$\langle x_n, y\rangle \to \langle x, y\rangle \quad \text{as } n \to \infty, \quad \text{for all } y \in E.$$

Every STRONGLY CONVERGENT sequence is also weakly convergent (but the opposite does not usually hold). This can be seen as follows. Consider the sequence $\{x_n\}$ that converges strongly to x, i.e., $\|x_n - x\| \to 0$ as $n \to \infty$. SCHWARZ'S INEQUALITY now gives

$$|\langle x_n - x, y\rangle| \leq \|x_n - x\| \, \|y\| \quad \text{as } n \to \infty.$$

The definition of weak convergence is therefore satisfied.

see also INNER PRODUCT SPACE, SCHWARZ'S INEQUALITY, STRONG CONVERGENCE

Weak Law of Large Numbers

Also known as BERNOULLI'S THEOREM. Let $x_1, \ldots, x_n$ be a sequence of independent and identically distributed random variables, each having a MEAN $\langle xi\rangle = \mu$ and STANDARD DEVIATION σ. Define a new variable

$$x \equiv \frac{x_1 + \ldots + x_n}{n}. \tag{1}$$

Then, as $n \to \infty$, the sample mean $\langle x\rangle$ equals the population MEAN μ of each variable.

$$\langle x\rangle = \left\langle \frac{x_1 + \ldots + x_n}{n} \right\rangle = \frac{1}{n}(\langle x_1\rangle + \ldots + \langle x_n\rangle) = \frac{n\mu}{n} = \mu \tag{2}$$

$$\begin{aligned} \operatorname{var}(x) &= \operatorname{var}\left(\frac{x_1 + \ldots + x_2}{n}\right) \\ &= \operatorname{var}\left(\frac{x_1}{n}\right) + \ldots + \operatorname{var}\left(\frac{x_n}{n}\right) \\ &= \frac{\sigma^2}{n^2} + \ldots + \frac{\sigma^2}{n^2} = \frac{\sigma^2}{n}. \end{aligned} \tag{3}$$

Therefore, by the CHEBYSHEV INEQUALITY, for all $\epsilon > 0$,

$$P(|x - \mu| \geq \epsilon) \leq \frac{\operatorname{var}(x)}{\epsilon^2} = \frac{\sigma^2}{n\epsilon^2}. \tag{4}$$

As $n \to \infty$, it then follows that

$$\lim_{n\to\infty} P(|x-\mu| \geq \epsilon) = 0 \tag{5}$$

for ϵ arbitrarily small; i.e., as $n \to \infty$, the sample MEAN is the same as the population MEAN.

Stated another way, if an event occurs x times in s TRIALS and if p is the probability of success in a single TRIAL, then the probability that the relative frequency of successes is x/s differs from p by less than any arbitrary POSITIVE quantity ϵ which approaches 1 as $s \to \infty$.

see also LAW OF TRULY LARGE NUMBERS, STRONG LAW OF LARGE NUMBERS

Weakly Binary Tree

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

A ROOTED TREE for which the ROOT is adjacent to at most two VERTICES, and all nonroot VERTICES are adjacent to at most three VERTICES. Let $b(n)$ be the number of weakly binary trees of order n, then $b(5) = 6$. Let

$$g(z) = \sum_{i=0}^{\infty} g_i z^i, \tag{1}$$

where

$$g_0 = 0 \tag{2}$$

$$g_1 = g_2 = g_3 = 1 \tag{3}$$

$$g_{2i+1} = \sum_{j=1}^{i} g_{2i+1-j} g_j \tag{4}$$

$$g_{2i} = \tfrac{1}{2} g_i(g_i+1) + \sum_{j=1}^{i-1} g_{2i-j} g_j. \tag{5}$$

Otter (Otter 1948, Harary and Palmer 1973, Knuth 1969) showed that

$$\lim_{n\to\infty} \frac{b(n) n^{3/2}}{\xi^n} = \eta, \tag{6}$$

where

$$\xi = 2.48325\ldots \tag{7}$$

is the unique POSITIVE ROOT of

$$g\left(\frac{1}{x}\right) = 1,$$

and

$$\eta = 0.7916032\ldots. \tag{8}$$

ξ is also given by

$$\xi = \lim_{n\to\infty} (c_n)^{2^{-n}}, \tag{9}$$

where c_n is given by

$$c_0 = 2 \tag{10}$$

$$c_n = (c_{n-1})^2 + 2, \tag{11}$$

giving

$$\eta = \frac{1}{2}\sqrt{\frac{\xi}{\pi}}\sqrt{3 + \frac{1}{c_1} + \frac{1}{c_1c_2} + \frac{1}{c_1c_2c_3} + \ldots}. \tag{12}$$

Weakly Complete Sequence

A SEQUENCE of numbers $V = \{\nu_n\}$ is said to be weakly complete if every POSITIVE INTEGER n beyond a certain point N is the sum of some SUBSEQUENCE of V (Honsberger 1985). Dropping two terms from the FIBONACCI NUMBERS produces a SEQUENCE which is not even weakly complete. However, the SEQUENCE

$$F_n' \equiv F_n - (-1)^n$$

is weakly complete, even with any finite subsequence deleted (Graham 1964).

Weakly Independent

An infinite sequence $\{a_i\}$ of POSITIVE INTEGERS is called weakly independent if any relation $\sum \epsilon_i a_i$ with $\epsilon_i = 0$ or ± 1 and $\epsilon_i = 0$, except finitely often, IMPLIES $\epsilon_i = 0$ for all i.

Weber Differential Equations

Consider the differential equation satisfied by

$$w = z^{-1/2} W_{k,-1/4}(\tfrac{1}{2}z^2), \tag{1}$$

where W is a WHITTAKER FUNCTION.

$$\frac{d}{z\,dz}\left[\frac{d(wz^{1/2})}{z\,dz}\right] + \left(-\frac{1}{4} + \frac{2k}{z^2} + \frac{3}{4z^4}\right) wz^{1/2} = 0 \tag{2}$$

$$\frac{d^2 w}{dz^2} + (2k - \tfrac{1}{4}z^2)w = 0. \tag{3}$$

This is usually rewritten

$$\frac{d^2 D_n(z)}{dz^2} + (n + \tfrac{1}{2} - \tfrac{1}{4}z^2)D_n(z) = 0. \tag{4}$$

The solutions are PARABOLIC CYLINDER FUNCTIONS.

The equations

$$\frac{d^2 U}{du^2} - (c + k^2 u^2)U = 0 \tag{5}$$

$$\frac{d^2 V}{dv^2} + (c - k^2 v^2)V = 0, \tag{6}$$

which arise by separating variables in LAPLACE'S EQUATION in PARABOLIC CYLINDRICAL COORDINATES, are also known as the Weber differential equations. As above, the solutions are known as PARABOLIC CYLINDER FUNCTIONS.

Weber's Discontinuous Integrals

$$\int_0^\infty J_0(ax)\cos(cx)\,dx = \begin{cases} 0 & a < c \\ \frac{1}{\sqrt{a^2-c^2}} & a > c \end{cases}$$

$$\int_0^\infty J_0(ax)\sin(cx)\,dx = \begin{cases} \frac{1}{\sqrt{c^2-a^2}} & a < c \\ 0 & a > c, \end{cases}$$

where $J_0(z)$ is a zeroth order BESSEL FUNCTION OF THE FIRST KIND.

References

Bowman, F. *Introduction to Bessel Functions.* New York: Dover, pp. 59–60, 1958.

Weber's Formula

$$\frac{1}{2p^2} e^{-(a^2+b^2)/(4p^2)} I_\nu\left(\frac{ab}{2p^2}\right) = \int_0^\infty e^{-p^2t^2} J_\nu(at) J_\nu(bt) t\,dt,$$

where $\Re[\nu] > -1$, $|\arg p| < \pi/4$, and a, $b > 0$, $J_\nu(z)$ is a BESSEL FUNCTION OF THE FIRST KIND, and $I_\nu(z)$ is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND.

Weber Functions

Although BESSEL FUNCTIONS OF THE SECOND KIND are sometimes called Weber functions, Abramowitz and Stegun (1972) define a separate Weber function as

$$\mathcal{E}_\nu(z) = \frac{1}{\pi}\int_0^\pi \sin(\nu\theta - z\sin\theta)\,d\theta. \tag{1}$$

Letting $\zeta_n = e^{2\pi i/m}$ be a ROOT OF UNITY, another set of Weber functions is defined as

$$f(z) = \frac{\eta(\frac{1}{2}(z+1))}{\zeta_{48}\eta(z)} \tag{2}$$

$$f_1(z) = \frac{\eta(\frac{1}{2}z)}{\eta(z)} \tag{3}$$

$$f_2(z) = \sqrt{2}\frac{\eta(2z)}{\eta(z)} \tag{4}$$

$$\gamma_2 = \frac{f^{24}(z) - 16}{f^8(z)} \tag{5}$$

$$\gamma_3 = \frac{[f^{24}(z) + 8][f_1{}^8(z) - f_2{}^8(z)]}{f^8(z)} \tag{6}$$

(Weber 1902, Atkin and Morain 1993), where $\eta(z)$ is the DEDEKIND ETA FUNCTION. The Weber functions satisfy the identities

$$f(z+1) = \frac{f_1(z)}{\zeta_{48}} \tag{7}$$

$$f_1(z+1) = \frac{f(z)}{\zeta_{48}} \tag{8}$$

$$f_2(z+1) = \zeta_{24} f_2(z) \tag{9}$$

$$f\left(-\frac{1}{z}\right) = f(z) \tag{10}$$

$$f_1\left(-\frac{1}{z}\right) = f_2(z) \tag{11}$$

$$f_2\left(-\frac{1}{z}\right) = f_1(z) \tag{12}$$

(Weber 1902, Atkin and Morain 1993).

Wedderburn's Theorem

A FINITE DIVISION RING is a FIELD.

Weddle's Rule

$$\int_{x_1}^{x_{6n}} f(x)\,dx = \tfrac{3}{10}h(f_1 + 5f_2 + f_3$$
$$+6f_4 + 5f_5 + f_6 + \ldots + 5f_{6n-1} + f_{6n})$$

see also BODE'S RULE, HARDY'S RULE, NEWTON-COTES FORMULAS, SIMPSON'S 3/8 RULE, SIMPSON'S RULE, TRAPEZOIDAL RULE, WEDDLE'S RULE

Wedge

A right triangular PRISM turned so that it rests on one of its lateral faces.

see also CONICAL WEDGE, CYLINDRICAL WEDGE, PRISM

Wedge Product

An antisymmetric operation on DIFFERENTIAL FORMS (also called the EXTERIOR DERIVATIVE)

$$dx_i \wedge dx_j = -dx_j \wedge dx_i, \tag{1}$$

which IMPLIES

$$\begin{aligned} dx_i \wedge dx_i &= 0 && (2)\\ b_i \wedge dx_j &= dx_j \wedge b_i = b_i\,dx_j && (3)\\ dx_i \wedge (b_i\,dx_j) &= b_i\,dx_i \wedge dx_j && (4)\\ \theta_1 \wedge \theta_2 &= (b_1\,dx_1 + b_2\,dx_2) \wedge (c_1\,dx_1 + c_2\,dx_2)\\ &= (b_1c_2 - b_2c_1)\,dx_1 \wedge dx_2\\ &= -\theta_2 \wedge \theta_1. && (5) \end{aligned}$$

The wedge product is ASSOCIATIVE

$$(s \wedge t) \wedge u = s \wedge (t \wedge u), \tag{6}$$

and BILINEAR

$$(\alpha_1 s_1 + \alpha_2 s_2) \wedge t = \alpha_1(s_1 \wedge t) + \alpha_2(s_2 \wedge t) \tag{7}$$

$$s \wedge (\alpha_1 t_1 + \alpha_2 t_2) = \alpha_1(s \wedge t_1) + \alpha_2(s \wedge t_2), \tag{8}$$

but not (in general) COMMUTATIVE

$$s \wedge t = (-1)^{pq}(t \wedge s), \tag{9}$$

where s is a p-form and t is a q-form. For a 0-form s and 1-form t,

$$(s \wedge t)_\mu = st_\mu. \tag{10}$$

For a 1-form s and 1-form t,

$$(s \wedge t)_{\mu\nu} = \tfrac{1}{2}(s_\mu t_\nu - s_\nu t_\mu). \tag{11}$$

The wedge product is the "correct" type of product to use in computing a VOLUME ELEMENT

$$dV = dx_1 \wedge \ldots \wedge dx_n. \tag{12}$$

see also DIFFERENTIAL FORM, EXTERIOR DERIVATIVE, INNER PRODUCT, VOLUME ELEMENT

Weekday

The day of the week W for a given day of the month D, month M, and year $100C + Y$ can be determined from the simple equation

$$W \equiv D + \lfloor 2.6M - 0.2 \rfloor + \left\lfloor \tfrac{1}{4}Y \right\rfloor + \left\lfloor \tfrac{1}{4}C \right\rfloor - 2C \pmod 7,$$

where *months are numbered beginning with March* and $W = 0$ for Sunday, $W = 1$ for Monday, etc. (Uspensky and Heaslet 1939, Vardi 1991).

A more complicated form is given by

$$W \equiv D + M + C + Y \pmod 7,$$

where $W = 1$ for Sunday, $W = 2$ for Monday, etc. and the numbers assigned to months, centuries, and years are given in the tables below (Kraitchik 1942, pp. 110–111).

Weibull Distribution

The Weibull distribution is given by

$$P(x) = \alpha\beta^{-\alpha}x^{\alpha-1}e^{-(x/\beta)^\alpha} \tag{1}$$

$$D(x) = 1 - e^{-(x/\beta)^\alpha} \tag{2}$$

for $x \in [0, \infty)$ (*Mathematica*® `Statistics'ContinuousDistributions'WeibullDistribution[a,b]`, Wolfram Research, Champaign, IL). The MEAN, VARIANCE, SKEWNESS, and KURTOSIS of this distribution are

$$\mu = \beta\Gamma(1+\alpha^{-1}) \tag{3}$$

$$\sigma^2 = \beta^2[\Gamma(1+2\alpha^{-1}) - \Gamma^2(1+\alpha^{-1})] \tag{4}$$

$$\gamma_1 = \frac{2\Gamma^3(1+\alpha^{-1}) - 3\Gamma(1+\alpha^{-1})\Gamma(1+2\alpha^{-1})}{[\Gamma(1+2\alpha^{-1}) - \Gamma^2(1+\alpha^{-1})]^{3/2}} + \frac{\Gamma(1+3\alpha^{-1})}{[\Gamma(1+2\alpha^{-1}) - \Gamma^2(1+\alpha^{-1})]^{3/2}} \tag{5}$$

$$\gamma_2 = \frac{f(a)}{[\Gamma(1+2\alpha^{-1}) - \Gamma^2(1+\alpha^{-1})]^2}, \tag{6}$$

where $\Gamma(z)$ is the GAMMA FUNCTION and

$$\begin{aligned} f(a) \equiv -6\Gamma^4(1+\alpha^{-1}) + 12\Gamma^2(1+\alpha^{-1})\Gamma(1+2\alpha^{-1}) \\ -3\Gamma^2(1+2\alpha^{-1}) - 4\Gamma(1+\alpha^{-1})\Gamma(1+3\alpha^{-1}) \\ +\Gamma(1+4\alpha^{-1}). \end{aligned} \tag{7}$$

A slightly different form of the distribution is

$$P(x) = \frac{\alpha}{\beta}x^{\alpha-1}e^{-x^\alpha/\beta} \tag{8}$$

$$D(x) = 1 - e^{-x^\alpha/\beta} \tag{9}$$

(Mendenhall and Sincich 1995). The MEAN and VARIANCE for this form are

$$\mu = \beta^{1/\alpha}\Gamma(1+\alpha^{-1}) \tag{10}$$

$$\sigma^2 = \beta^{2/\alpha}[\Gamma(1+2\alpha^{-1}) - \Gamma^2(1+\alpha^{-1})]. \tag{11}$$

The Weibull distribution gives the distribution of lifetimes of objects. It was originally proposed to quantify fatigue data, but it is also used in analysis of systems involving a "weakest link."

Weierstraß Approximation Theorem

If f is continuous on $[a, b]$, then there exists a POLYNOMIAL p on $[a, b]$ such that

$$|f(x) - P(x)| < \epsilon$$

for all $x \in [a, b]$ and $\epsilon > 0$. In words, any continuous function on a closed and bounded interval can be uniformly approximated on that interval by POLYNOMIALS to any degree of accuracy.

see also MÜNTZ'S THEOREM

Weierstraß-Casorati Theorem

An ANALYTIC FUNCTION approaches any given value arbitrarily closely in any ϵ-NEIGHBORHOOD of an ESSENTIAL SINGULARITY.

Weierstraß Constant

$$\sigma(\tfrac{1}{2}) = \tfrac{1}{2} \prod_{\substack{(m,n)\neq\\(0,0)}} \left[1 - \frac{1}{2(m+ni)}\right] \times e^{1/[2(m+ni)]+1/[8(m+ni)^2]}$$
$$= \frac{2^{5/4}\sqrt{\pi}\, e^{\pi/8}}{\Gamma^2(\frac{1}{4})} = 0.4749493799\ldots.$$

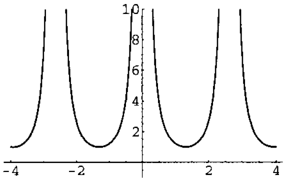
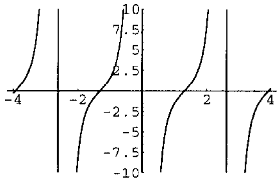
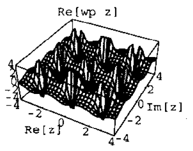
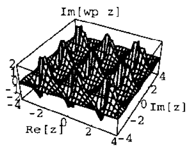
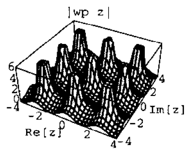
Weierstraß Elliptic Function

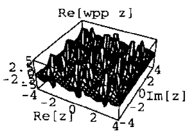


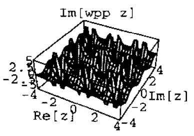


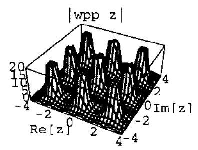












The Weierstraß elliptic functions are elliptic functions which, unlike the JACOBI ELLIPTIC FUNCTIONS, have a second-order POLE at $z = 0$. The above plots show the Weierstraß elliptic function $\wp(z)$ and its derivative $\wp'(z)$ for invariants (defined below) of $g_2 = 0$ and $g_3 = 0$. Weierstraß elliptic functions are denoted $\wp(z)$ and can be defined by

$$\wp(z) = \frac{1}{z^2} + \sum_{m,n=-\infty}^{\infty}{}' \left[\frac{1}{(z - 2m\omega_1 - 2n\omega_2)^2} - \frac{1}{(2m\omega_1 + 2n\omega_2)^2}\right]. \quad (1)$$

Write $\Omega_{mn} \equiv 2m\omega_1 + 2n\omega_2$. Then this can be written

$$\wp(z) = z^{-2} + \sum_{m,n}{}' [(z - \Omega_{mn})^{-2} - \Omega_{mn}^{-2}]. \quad (2)$$

An equivalent definition which converges more rapidly is

$$\wp(z) = \left(\frac{\pi}{2\omega_1}\right)^2 \left[-\frac{1}{3} + \sum_{-\infty}^{\infty} \csc^2\left(\frac{z - 2n\omega_2}{2\omega_1}\pi\right) - \sum_{n=-\infty}^{\infty}{}' \csc^2\left(\frac{n\omega_2}{n_1}\pi\right)\right]. \quad (3)$$

$\wp(z)$ is an EVEN FUNCTION since $\wp(-z)$ gives the same terms in a different order. To specify $\wp$ completely, its periods or invariants, written $\wp(z|\omega_1, \omega_2)$ and $\wp(z; g_2, g_3)$, respectively, must also be specified.

The differential equation from which Weierstraß elliptic functions arise can be found by expanding about the origin the function $f(z) \equiv \wp(z) - z^{-2}$.

$$\wp(z) - z^{-2} = f(0) + f'(0)z + \tfrac{1}{2!}f''(0)z^2 + \tfrac{1}{3!}f'''(0)z^3 + \tfrac{1}{4}f^{(4)}(0)z^4 + \ldots. \quad (4)$$

But $f(0) = 0$ and the function is even, so $f'(0) = f'''(0) = 0$ and

$$f(z) = \wp(z) - z^{-2} = \tfrac{1}{2!}f''(0)z^2 + \tfrac{1}{4}f^{(4)}(0)z^4 + \ldots. \quad (5)$$

Taking the derivatives

$$f' = -2\Sigma'[(z - \Omega_{mn})^{-3}] \quad (6)$$
$$f'' = 6\Sigma'(z - \Omega_{mn})^{-4} \quad (7)$$
$$f''' = -24\Sigma'(z - \Omega_{mn})^{-5} \quad (8)$$
$$f^{(4)} = 120\Sigma'(z - \Omega_{mn})^{-6}. \quad (9)$$

So

$$f''(0) = 6\Sigma'\Omega_{mn}^{-4} \quad (10)$$
$$f^{(4)}(0) = 120\Sigma'\Omega_{mn}^{-6}. \quad (11)$$

Plugging in,

$$\wp(z) - z^{-2} = 3\Sigma'\Omega_{mn}^{-4}z^2 + 5\Sigma'\Omega_{mn}^{-6}z^4 + \mathcal{O}(z^6). \quad (12)$$

Define the INVARIANTS

$$g_2 \equiv 60\Sigma'\Omega_{mn}^{-4} \quad (13)$$
$$g_3 \equiv 140\Sigma'\Omega_{mn}^{-6}, \quad (14)$$

then

$$\wp(z) = z^{-2} + \tfrac{1}{20}g_2z^2 + \tfrac{1}{28}g_3z^4 + \mathcal{O}(z^6) \quad (15)$$

$$\wp'(z) = -2z^{-3} + \tfrac{1}{10}g_2z + \tfrac{1}{7}g_3z^3 + \mathcal{O}(z^5). \quad (16)$$

Now cube (15) and square (16)

$$\wp^3(z) = z^{-6} + \tfrac{3}{20}g_2z^{-2} + \tfrac{3}{28}g_3 + \mathcal{O}(z^2) \quad (17)$$

$$\wp'^2(z) = 4z^{-6} - \tfrac{2}{5} g_2 z^{-2} - \tfrac{4}{7} g_3 + \mathcal{O}(z^2). \tag{18}$$

Taking (18) – 4 × (17) cancels out the z^{-6} term, giving

$$\begin{aligned} \wp'^2(z) - 4\wp^3(z) & \\ &= \left(-\tfrac{2}{5} - \tfrac{3}{5}\right) g_2 z^{-2} + \left(-\tfrac{4}{7} - \tfrac{3}{7}\right) g_3 + \mathcal{O}(z^2) \\ &= -g_2 z^{-2} - g_3 + \mathcal{O}(z^2) \end{aligned} \tag{19}$$

$$\wp'^2(z) - 4\wp^3(z) + g_2 z^{-2} + g_3 = \mathcal{O}(z^2). \tag{20}$$

But, from (5)

$$\wp(z) = z^{-2} + \tfrac{1}{2!} f''(0) z^2 + \tfrac{1}{4} f^{(4)}(0) z^4 + \ldots, \tag{21}$$

so $\wp(z) = z^{-2} + \mathcal{O}(z^2)$ and (20) can be written

$$\wp'^2(z) - 4\wp^3(z) + g_2 \wp(z) + g_3 = \mathcal{O}(z^2). \tag{22}$$

The Weierstraß elliptic function is analytic at the origin and therefore at all points congruent to the origin. There are no other places where a singularity can occur, so this function is an ELLIPTIC FUNCTION with no SINGULARITIES. By LIOUVILLE'S ELLIPTIC FUNCTION THEOREM, it is therefore a constant. But as $z \to 0$, $\mathcal{O}(z^2) \to 0$, so

$$\wp'^2(z) = 4\wp^3(z) - g_2 \wp(z) - g_3. \tag{23}$$

The solution to the differential equation

$$y'^2 = 4y^3 - g_2 y - g_3 \tag{24}$$

is therefore given by $y = \wp(z + \alpha)$, providing that numbers ω_1 and ω_2 exist which satisfy the equations defining the INVARIANTS. Writing the differential equation in terms of its roots e_1, e_2, and e_3,

$$y'^2 = 4y^3 - g_2 y - g_3 = 4(y - e_1)(y - e_2)(y - e_3) \tag{25}$$

$$2\ln(y') = \ln 4 + \sum_{r=1}^{3} \ln(y - e_r) \tag{26}$$

$$\frac{2y''}{y'} = y' \sum_{r=1}^{3} (y - e_r)^{-1} \tag{27}$$

$$\frac{2y''}{y'^2} = \sum_{r=1}^{3} (y - e_r)^{-1} \tag{28}$$

$$2\frac{y'^2 y''' - y''(2y'y'')}{y'^4} = -y' \sum_{r=1}^{3} (y - e_r)^{-2} \tag{29}$$

$$\frac{2y'''}{y'^3} - \frac{4y''^2}{y'^4} = -\sum_{r=1}^{3} (y - e_r)^{-2}. \tag{30}$$

Now take $(30)/4 + [(30)/4]^2$,

$$\begin{aligned} \left[\frac{y'''}{2y'^3} - \frac{y''^2}{y'^4}\right] + \left[\frac{y''^2}{4y'^4}\right] & \\ &= -\frac{1}{4} \sum_{r=1}^{3} (y - e_r)^{-2} + \frac{1}{16} \left[\sum_{r=1}^{3} (y - e_r)^{-1}\right]^2 \end{aligned} \tag{31}$$

$$\frac{3y''^2}{4y'^4} - \frac{y'''}{2y'^3} = \tfrac{3}{16} \sum_{r=1}^{3} (y - e_r)^{-2} - \tfrac{3}{8} y \prod_{r=1}^{3} (y - e_r)^{-1}. \tag{32}$$

The term on the right is half the SCHWARZIAN DERIVATIVE.

The DERIVATIVE of the Weierstraß elliptic function is given by

$$\begin{aligned} \wp'(z) &= \frac{d}{dz} \wp(z) = -2 \sum_{m,n} \frac{1}{(z - \Omega_{mn})^3} \\ &= -2z^{-3} - 2 \sum_{m,n}{}' (z - \Omega_{mn})^{-3}. \end{aligned} \tag{33}$$

This is an ODD FUNCTION which is itself an elliptic function with pole of order 3 at $z = 0$. The INTEGRAL is given by

$$z = \int_{\wp(z)}^{\infty} (4t^3 - g_2 t - g_3)^{-1/2} \, dt. \tag{34}$$

A duplication formula is obtained as follows.

$$\begin{aligned} \wp(2z) &= \lim_{y \to z} \wp(y + z) = \frac{1}{4} \lim_{y \to z} \left[\frac{\wp'(z) - \wp'(y)}{\wp(z) - \wp(y)}\right]^2 \\ &\quad - \wp(z) - \lim_{y \to z} \wp(y) \\ &= \frac{1}{4} \lim_{h \to 0} \left[\frac{\wp(z) - \wp'(z + h)}{\wp(z) - \wp(z + h)}\right]^2 - 2\wp(z) \\ &= \frac{1}{4} \left\{ \left[\lim_{h \to 0} \frac{\wp'(z) - \wp'(z + h)}{h}\right] \left[\lim_{h \to 0} \frac{h}{\wp(z) - \wp(z + h)}\right] \right\}^2 \\ &\quad - 2\wp(z) \\ &= \frac{1}{4} \left[\frac{\wp''(z)}{\wp'(z)}\right]^2 - 2\wp(z). \end{aligned} \tag{35}$$

A general addition theorem is obtained as follows. Given

$$\wp'(z) = A\wp(z) + B \tag{36}$$

$$\wp'(y) = A\wp(y) + B \tag{37}$$

with zero y and z where $z \not\equiv \pm y \pmod{2\omega_1, 2\omega_2}$, find the third zero ζ. Consider $\wp'(\zeta) - A\wp(\zeta) - B$. This has a pole of order three at $\zeta = 0$, but the sum of zeros (= 0) equals the sum of poles for an ELLIPTIC FUNCTION, so $z + y + \zeta = 0$ and $\zeta = -z - y$.

$$\wp'(-z - y) = A\wp(-z - y) + B \tag{38}$$

$$-\wp'(z+y) = A\wp(z+y)+B. \tag{39}$$

Combining (36), (37), and (39) gives

$$\begin{bmatrix} \wp(z) & \wp'(z) & 1 \\ \wp(y) & \wp'(y) & 1 \\ \wp(z+y) & -\wp(z+y) & 1 \end{bmatrix} \begin{bmatrix} A \\ -1 \\ B \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}, \tag{40}$$

so

$$\begin{vmatrix} \wp(z) & \wp'(z) & 1 \\ \wp(y) & \wp'(y) & 1 \\ \wp(z+y) & -\wp(z+y) & 1 \end{vmatrix} = 0. \tag{41}$$

Defining $u+v+w=0$ where $u \equiv z$ and $v \equiv y$ gives the symmetric form

$$\begin{vmatrix} \wp(u) & \wp'(u) & 1 \\ \wp(v) & \wp'(v) & 1 \\ \wp(w) & \wp(w) & 1 \end{vmatrix} = 0. \tag{42}$$

To get the expression explicitly, start again with

$$\wp'(\zeta) - A\wp(\zeta) - B = 0, \tag{43}$$

where $\zeta = z, y, -z-y$.

$$\wp'^2(\zeta) - [A\wp(\zeta)+B]^2 = 0. \tag{44}$$

But $\wp^2(\zeta) = 4\wp^4(\zeta) - g_2\wp(\zeta) - g_3$, so

$$4\wp^3(\zeta) - A^2\wp^2(\zeta) - (2AB+g_2)\wp(\zeta) - (B^2+g_3) = 0. \tag{45}$$

The solutions $\wp(\zeta) \equiv z$ are given by

$$4z^3 - A^2z^2 - (2AB+g_2)z - (B^2+g_3) = 0. \tag{46}$$

But the sum of roots equals the COEFFICIENT of the squared term, so

$$\wp(z)+\wp(y)+\wp(z+y) = \tfrac{1}{4}A^2 \tag{47}$$

$$\wp'(z) - \wp'(y) = A[\wp(z)-\wp(y)] \tag{48}$$

$$A = \frac{\wp'(z)-\wp'(y)}{\wp(z)-\wp(y)} \tag{49}$$

$$\wp(z+y) = \frac{1}{4}\left[\frac{\wp(z)-\wp'(y)}{\wp(z)-\wp(y)}\right]^2 - \wp(z) - \wp(y). \tag{50}$$

Half-period identities include

$$\begin{aligned} x \equiv \wp(\tfrac{1}{2}\omega_1) = \wp(-h\omega_1+\omega_1) &= e_1 + \frac{(e_1-e_2)(e_1-e_3)}{\wp(-\tfrac{1}{2}\omega_1)-e_1} \\ &= e_1 + \frac{(e_1-e_2)(e_1-e_3)}{x-e_1}. \end{aligned} \tag{51}$$

Multiplying through,

$$x^2 - e_1x = e_1x - e_1{}^2 + (e_1-e_2)(e_1-e_3) \tag{52}$$

$$x^2 - 2e_1 + [e_1{}^2 - (e_1-e_2)(e_1-e_3)] = 0, \tag{53}$$

which gives

$$\begin{aligned} \wp(\tfrac{1}{2}\omega_1) &= \tfrac{1}{2}\left\{2e_1 \pm \sqrt{4e_1{}^2 - 4[e_1{}^2-(e_1-e_2)(e_1-e_3)]}\right\} \\ &= e_1 \pm \sqrt{(e_1-e_2)(e_1-e_3)}. \end{aligned} \tag{54}$$

From Whittaker and Watson (1990, p. 445),

$$\begin{aligned} \wp'(\tfrac{1}{2}\omega_1) = -2\sqrt{(e_1-e_2)(e_1-e_3)} \\ \times(\sqrt{e_1-e_2}+\sqrt{e_1-e_3}). \end{aligned} \tag{55}$$

The function is HOMOGENEOUS,

$$\wp(\lambda z|\lambda\omega_1, \lambda\omega_2) = \lambda^{-2}\wp(z|\omega_1,\omega_2) \tag{56}$$

$$\wp(\lambda z; \lambda^{-4}g_2, \lambda^{-6}g_3) = \lambda^{-2}\wp(z;g_2,g_3). \tag{57}$$

To invert the function, find $2\omega_1$ and $2\omega_2$ of $\wp(z|\omega_1,\omega_2)$ when given $\wp(z;g_2,g_3)$. Let e_1, e_2, and e_3 be the roots such that $(e_1-e_2)/(e_1-e_3)$ is not a REAL NUMBER > 1 or < 0. Determine the PARAMETER τ from

$$\frac{e_1-e_2}{e_1-e_3} = \frac{\vartheta_4{}^4(0|\tau)}{\vartheta_3{}^4(0|\tau)}. \tag{58}$$

Now pick

$$A \equiv \frac{\sqrt{e_1-e_2}}{\vartheta_4{}^2(0|\tau)}. \tag{59}$$

As long as $g_2{}^3 \neq 27g_3$, the periods are then

$$2\omega_1 = \pi A \tag{60}$$

$$2\omega_2 = \frac{\pi\tau}{A}. \tag{61}$$

Weierstraß elliptic functions can be expressed in terms of JACOBI ELLIPTIC FUNCTIONS by

$$\begin{aligned} \wp(u;g_2,g_3) = e_3 + (e_1-e_3) \\ \times \mathrm{ns}^2\left(u\sqrt{e_1-e_3}, \sqrt{\frac{e_2-e_3}{e_1-e_3}}\right), \end{aligned} \tag{62}$$

where

$$\wp(\omega_1) = e_1 \tag{63}$$

$$\wp(\omega_2) = e_2 \tag{64}$$

$$\wp(\omega_3) = -\wp(-\omega_1-\omega_2) = e_3, \tag{65}$$

and the INVARIANTS are

$$g_2 \equiv 60\Sigma'\Omega_{mn}^{-4} \tag{66}$$

$$g_3 \equiv 140\Sigma'\Omega_{mn}^{-6}. \tag{67}$$

Here, $\Omega_{mn} \equiv 2m\omega_1 - 2n\omega_2$.

An addition formula for the Weierstraß elliptic function can be derived as follows.

$$\wp(z+\omega_1)+\wp(z)+\wp(\omega_1)$$
$$=\frac{1}{4}\left[\frac{\wp'(z)-\wp'(\omega_1)}{\wp(z)-\wp(\omega_1)}\right]^2=\frac{1}{4}\frac{\wp'^2(z)}{[\wp(z)-e_1]^2}. \quad (68)$$

Use

$$\wp'(z)=4\prod_{r=1}^{3}[\wp(z)-e_r], \quad (69)$$

so

$$\begin{aligned}\wp(z+\omega_1)&=-\wp(z)-e_1+\frac{1}{4}\frac{4\prod_{r=1}^{3}[\wp(z)-e_r]}{[\wp(z)-e_1]^2}\\&=-\wp(z)-e_1+\frac{[\wp(z)-e_2][\wp(z)-e_3]}{\wp(z)-e_1}.\end{aligned} \quad (70)$$

Use $\sum_{r=1}^{3}e_r=0$,

$$\begin{aligned}\wp(z+\omega_1)&=e_1+\frac{[-2e_1-\wp(z)][\wp(z)-e_1]}{\wp(z)-e_1}\\&\quad+\frac{\wp^2(z)-\wp(z)(e_2+e_3)+e_2e_3}{\wp(z)-e_1}\\&=e_1+\frac{-\wp(z)(e_1+e_2+e_3)+e_2e_3+2{e_1}^2}{\wp(z)-e_1}.\end{aligned} \quad (71)$$

But $\sum_{r=1}^{3}e_r=0$ and

$$2{e_1}^2+e_2e_3={e_1}^2-e_1(e_2+e_3)+e_2e_3=(e_1-e_2)(e_1-e_3), \quad (72)$$

so

$$\wp(z+\omega_1)=e_1+\frac{(e_1-e_2)(e_1-e_3)}{\wp(z)-e_1}. \quad (73)$$

The periods of the Weierstraß elliptic function are given as follows. When g_2 and g_3 are REAL and ${g_2}^3-27{g_3}^2>0$, then e_1, e_2, and e_3 are REAL and defined such that $e_1>e_2>e_3$.

$$\omega_1=\int_{e_1}^{\infty}(4t^3-g_2t-g_3)^{-1/2}\,dt \quad (74)$$

$$\omega_3=-i\int_{-\infty}^{e_3}(g_3+g_2t-4t^3)^{-1/2}\,dt \quad (75)$$

$$\omega_2=-\omega_1-\omega_3. \quad (76)$$

The roots of the Weierstraß elliptic function satisfy

$$e_1=\wp(\omega_1) \quad (77)$$

$$e_2=\wp(\omega_2) \quad (78)$$

$$e_3=\wp(\omega_3), \quad (79)$$

where $\omega_3\equiv-\omega_1-\omega_2$. The e_is are ROOTS of $4t^3-g_2t-g_3$ and are unequal so that $e_1\neq e_2\neq e_3$. They can be found from the relationships

$$e_1+e_2+e_3=-a_2=0 \quad (80)$$

$$e_2e_3+e_3e_1+e_1e_2=a_1=-\tfrac{1}{4}g_2 \quad (81)$$

$$e_1e_2e_3=-a_0=\tfrac{1}{4}g_3. \quad (82)$$

Weierstraß-Erdman Corner Condition

In the CALCULUS OF VARIATIONS, the condition

$$f_{y'}(x,y,y'(x_-))=f_{y'}(x,y,y'(x_+))$$

must hold at a corner (x,y) of a minimizing arc E_{12}.

Weierstraß Extreme Value Theorem

see EXTREME VALUE THEOREM

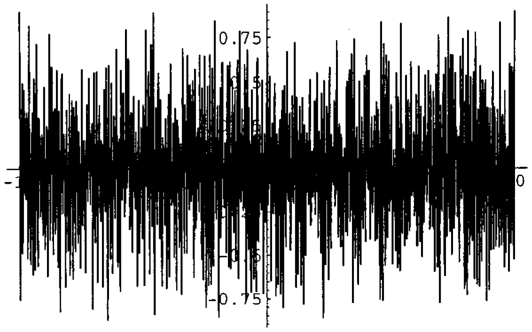
Weierstraß Form

A general form into which an ELLIPTIC CURVE over any FIELD K can be transformed is called the Weierstraß form, and is given by

$$y^2+ay=x^3+bx^2+cxy+dx+e,$$

where a, b, c, d, and e are elements of K.

Weierstraß Function



A CONTINUOUS FUNCTION which is nowhere DIFFERENTIABLE. It is given by

$$f(x) = \sum_{n=1}^{\infty} b^n \cos(a^n \pi x)$$

where n is an ODD INTEGER, $b \in (0,1)$, and $ab > 1 + 3\pi/2$. The above plot is for $a = 10$ and $b = 1/2$.

Weierstraß's Gap Theorem

Given a succession of nonsingular points which are on a nonhyperelliptic curve of GENUS p, but are not a group of the canonical series, the number of groups of the first k which cannot constitute the group of simple POLES of a RATIONAL FUNCTION is p. If points next to each other are taken, then the theorem becomes: Given a nonsingular point of a nonhyperelliptic curve of GENUS p, then the orders which it cannot possess as the single pole of a RATIONAL FUNCTION are p in number.

Weierstraß Sigma Function

The QUASIPERIODIC FUNCTION defined by

$$\frac{d}{dz} \ln \sigma(z) = \zeta(z), \tag{1}$$

where $\zeta(z)$ is the WEIERSTRAß ZETA FUNCTION and

$$\lim_{z \to 0} \frac{\sigma(z)}{z} = 1. \tag{2}$$

Then

$$\sigma(z) = z \prod_{mn}{}' \left[\left(1 - \frac{z}{\Omega_{mn}}\right) \exp\left(\frac{z}{\Omega_{mn}} + \frac{z^2}{2\Omega_{mn}^2}\right) \right] \tag{3}$$

$$\sigma(z + 2\omega_1) = -e^{2\eta_1(z+\omega_1)} \sigma(z) \tag{4}$$

$$\sigma(z + 2\omega_2) = -e^{2\eta_2(z+\omega_2)} \sigma(z) \tag{5}$$

$$\sigma_r(z) = \frac{e^{-\eta_r z}\sigma(z+\omega_r)}{\sigma(\omega_r)} \tag{6}$$

for $r = 1, 2, 3$.

$$\sigma(z|\omega_1,\omega_2) = \frac{2\omega_1}{\pi\vartheta_1'}\exp\left(-\frac{\nu^2\vartheta_1'''}{6\vartheta_1'}\right)\vartheta_1\left(\nu\,\middle|\,\frac{\omega_2}{\omega_1}\right), \tag{7}$$

where $\nu \equiv \pi z/(2\omega_1)$, and

$$\eta_1 = -\frac{\pi^2\vartheta_1'''}{12\omega_1\vartheta_1'} \tag{8}$$

$$\eta_2 = -\frac{\pi^2\omega_2\vartheta_1'''}{12{\omega_1}^2\vartheta_1'} - \frac{\pi i}{2\omega_1}. \tag{9}$$

Weierstraß's Theorem

The only hypercomplex number systems with commutative multiplication and addition are the algebra with one unit such that $e = e^2$ and the GAUSSIAN INTEGERS.

see also GAUSSIAN INTEGER, PEIRCE'S THEOREM

Weierstraß Zeta Function

The QUASIPERIODIC FUNCTION defined by

$$\frac{d\zeta(z)}{dz} \equiv -\wp(z) \tag{1}$$

with

$$\lim_{z\to 0}[\zeta(z) - z^{-1}] = 0. \tag{2}$$

Then

$$\begin{aligned}\zeta(z) - z^{-1} &= -\int_0^z [\wp(z) - z^{-2}]\,dz\\ &= -\Sigma'\int_0^z [(z-\Omega_{mn})^{-2} - \Omega_{mn}^{-2}]\,dz \end{aligned} \tag{3}$$

$$\zeta(z) = z^{-1} + \sum_{m,n=-\infty}^{\infty}{}' [(z-\Omega_{mn})^{-1} + \Omega_{mn}^{-1} + z\Omega_{mn}^{-2}] \tag{4}$$

so $\zeta(z)$ is an ODD FUNCTION. Integrating $\wp(z+2\omega_1) = \wp(z)$ gives

$$\zeta(z+2\omega_1) = \zeta(z) + 2\eta_1. \tag{5}$$

Letting $z = -\omega_1$ gives $\zeta(-\omega_1) + 2\eta_1 = -\zeta(\omega_1) + 2\eta_1$, so $\eta_1 = \zeta(\omega_1)$. Similarly, $\eta_2 = \zeta(\omega_2)$. From Whittaker and Watson (1990),

$$\eta_1\omega_2 - \eta_2\omega_1 = \tfrac{1}{2}\pi i. \tag{6}$$

If $x + y + z = 0$, then

$$[\zeta(x) + \zeta(y) + \zeta(z)]^2 + \zeta'(x) + \zeta'(y)\zeta'(z) = 0. \tag{7}$$

Also,

$$2\frac{\begin{vmatrix} 1 & \wp(x) & \wp^2(x)\\ 1 & \wp(y) & \wp^2(y)\\ 1 & \wp(z) & \wp^2(z)\end{vmatrix}}{\begin{vmatrix} 1 & \wp(x) & \wp'(x)\\ 1 & \wp(y) & \wp'(y)\\ 1 & \wp(z) & \wp'(z)\end{vmatrix}} = \zeta(x+y+z) - \zeta(x) - \zeta(y) - \zeta(z) \tag{8}$$

(Whittaker and Watson 1990, p. 446).

Weighings

n weighings are SUFFICIENT to find a bad COIN among $(3^n - 1)/2$ COINS. vos Savant (1993) gives an algorithm for finding a bad ball among 12 balls in three weighings (which, in addition, determines if the bad ball is heavier or lighter than the other 11).

Bachet's weights problem asks for the *minimum number* of weights (which can be placed in *either* pan of a two-arm balance) required to weigh any integral number of pounds from 1 to 40. The solution is 1, 3, 9, and 27: 1, $2 = -1 + 3$, 3, $4 = 1 + 3$, $5 = -1 - 3 + 9$, $6 = -3 + 9$, $7 = 1 - 3 + 9$, $8 = -1 + 9$, 9, $10 = 1 + 9$, $11 = -1 + 3 + 9$, $12 = 3 + 9$, $13 = 1 + 3 + 9$, $14 = -1 - 3 - 9 + 27$, $15 = -3 - 9 + 27$, $16 = 1 - 3 - 9 + 27$, $17 = -1 - 9 + 27$, and so on.

Weight

The word weight has many uses in mathematics. It can refer to a function $w(x)$ (also called a WEIGHTING FUNCTION or WEIGHT FUNCTION) used to normalize ORTHONORMAL FUNCTIONS. It can also be used to indicate one of a set of a multiplicative constants placed in front of terms in a MOVING AVERAGE, NEWTON-COTES FORMULAS, edge or vertex of a GRAPH or TREE, etc.

see also WEIGHTED TREE, WEIGHTING FUNCTION

Weight Function

see WEIGHTING FUNCTION

Weighted Tree

A TREE in which each branch is given a numerical WEIGHT (i.e., a labelled TREE).

see also LABELLED GRAPH, TAYLOR'S CONDITION, TREE

Weighting Function

A function $w(x)$ used to normalize ORTHONORMAL FUNCTIONS

$$\int [f_n(x)]^2\, w(x)\, dx = N_n.$$

see also WEIGHT

Weingarten Equations

The Weingarten equations express the derivatives of the NORMAL using derivatives of the position vector. Let $\mathbf{x} : U \to \mathbb{R}^3$ a REGULAR PATCH, then the SHAPE OPERATOR S of $\mathbf{x}$ is given in terms of the basis $\{\mathbf{x}_u, \mathbf{x}_v\}$ by

$$-S(\mathbf{x}_u) = \mathbf{N}_u = \frac{fF - eG}{EG - F^2}\mathbf{x}_u + \frac{eF - fE}{EG - F^2}\mathbf{x}_v \qquad (1)$$

$$-S(\mathbf{x}_v) = \mathbf{N}_v = \frac{gF - fG}{EG - F^2}\mathbf{x}_u + \frac{fF - gE}{EG - F^2}\mathbf{x}_v, \qquad (2)$$

where $\mathbf{N}$ is the NORMAL VECTOR, E, F, and G the coefficients of the first FUNDAMENTAL FORM

$$ds^2 = E\, du^2 + 2F\, du\, dv + G\, dv^2, \qquad (3)$$

and e, f, and g the coefficients of the second FUNDAMENTAL FORM given by

$$e = -\mathbf{N}_u \cdot \mathbf{x}_u = \mathbf{N} \cdot \mathbf{x}_{uu} \qquad (4)$$

$$\begin{aligned} f &= -\mathbf{N}_v \cdot \mathbf{x}_u = \mathbf{N} \cdot \mathbf{x}_{uv} \\ &= \mathbf{N}_{vu} \cdot \mathbf{x}_{vu} = -\mathbf{N}_u \cdot \mathbf{x}_v \qquad (5) \end{aligned}$$

$$g = -\mathbf{N}_v \cdot \mathbf{x}_v = \mathbf{N} \cdot \mathbf{x}_{vv}. \qquad (6)$$

Weird Number

A number which is ABUNDANT without being SEMIPERFECT. (A SEMIPERFECT NUMBER is the sum of any set of its own DIVISORS.) The first few weird numbers are 70, 836, 4030, 5830, 7192, 7912, 9272, 10430, ... (Sloane's A006037). No ODD weird numbers are known, but an infinite number of weird numbers are known to exist. The SEQUENCE of weird numbers has POSITIVE SCHNIRELMANN DENSITY.

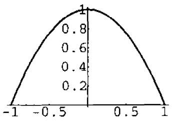
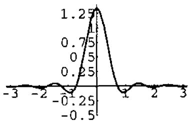
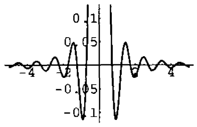
Welch Apodization Function







The APODIZATION FUNCTION

$$A(x) = 1 - \frac{x^2}{a^2}.$$

Its FULL WIDTH AT HALF MAXIMUM is $\sqrt{2}\,a$. Its INSTRUMENT FUNCTION is

$$\begin{aligned} I(k) &= a2\sqrt{2\pi}\,\frac{J_{3/2}(2\pi ka)}{(2\pi ka)^{3/2}} \\ &= a\frac{\sin(2\pi ka) - 2\pi ak\cos(2\pi ak)}{2a^3k^3\pi^3}, \end{aligned}$$

where $J_\nu(z)$ is a BESSEL FUNCTION OF THE FIRST KIND. It has a width of 1.59044, a maximum of $\frac{4}{3}$, maximum NEGATIVE sidelobe of -0.0861713 times the peak, and maximum POSITIVE sidelobe of 0.356044 times the peak.

see also APODIZATION FUNCTION, INSTRUMENT FUNCTION

Well-Defined

An expression is called well-defined (or UNAMBIGUOUS) if its definition assigns it a unique interpretation or value. Otherwise, the expression is said to not be well defined or to be AMBIGUOUS.

For example, the expression *abc* (the PRODUCT) is well-defined if a, b, and c are integers. Because integers are ASSOCIATIVE, *abc* has the same value whether it is interpreted to mean $(ab)c$ or $a(bc)$. However, if a, b, and c are MATRICES or CAYLEY NUMBERS, then the expression *abc* is *not* well-defined, since MATRICES and CAYLEY NUMBER are not, in general, ASSOCIATIVE, so that the two interpretations $(ab)c$ and $a(bc)$ can be different.

Sometimes, ambiguities are implicitly resolved by notational convention. For example, the conventional interpretation of $a \wedge b \wedge c = a^{b^c}$ is $a^{(b^c)}$, never $(a^b)^c$, so that the expression $a \wedge b \wedge c$ is well-defined even though exponentiation is nonassociative.

Well-Ordered Set

A SET having the property that every nonempty SUBSET has a least member.

see also AXIOM OF CHOICE, HILBERT'S PROBLEMS, SUBSET, WELL-ORDERING PRINCIPLE

Well-Ordering Principle

Every nonempty set of POSITIVE integers contains a smallest member.

see also WELL-ORDERED SET

Weyl Tensor

The TENSOR

$$C^{ij}{}_{kl} = R^i j_{kl} - 2\delta^{[i}{}_{[k} R^{j]}{}_{l]} + \tfrac{1}{3}\delta^{[i}{}_{[k}\delta^{j]}{}_{l]} R,$$

where $R^i j_{kl}$ is the RIEMANN TENSOR and R is the CURVATURE SCALAR. The Weyl tensor is defined so that every CONTRACTION between indices gives 0. In particular, $C^\lambda{}_{\mu\lambda\kappa} = 0$. The number of independent components for a Weyl tensor in N-D is given by

$$C_N = \tfrac{1}{12} N(N+1)(N+2)(N-3).$$

Wheat and Chessboard Problem

Let one grain of wheat be placed on the first square of a CHESSBOARD, two on the second, three on the third, etc. How many grains total are placed on an 8 × 8 CHESSBOARD? Since this is a GEOMETRIC SERIES, the answer for n squares is

$$\sum_{i=0}^{n-1} 2^i = 2^n - 1.$$

Plugging in $n = 8 \times 8 = 64$ then gives $2^{64} - 1 = 18446744073709551615$.

Whitney-Graustein Theorem

A 1937 theorem which classified planar regular closed curves up to regular HOMOTOPY by their WINDING NUMBERS. In his thesis, S. Smale generalized this result to regular closed curves on an n-MANIFOLD.

Whitney-Mikhlin Extension Constants

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Let $B_n(r)$ be the n-D closed BALL of RADIUS $r > 1$ centered at the ORIGIN. A function which is defined on $B(r)$ is called an extension to $B(r)$ of a function f defined on $B(1)$ if

$$F(x) = f(x) \forall\ x \in B(1). \tag{1}$$

Given 2 BANACH SPACES of functions defined on $B(1)$ and $B(r)$, find the extension operator from one to the other of minimal norm. Mikhlin (1986) found the best constants χ such that this condition, corresponding to the Sobolev $W(1,2)$ integral norm, is satisfied,

$$\sqrt{\int_{B(1)} \left[[f(x)]^2 + \sum_{j=1}^n \left(\frac{\partial f}{\partial x_j}\right)^2 \right] dx} \leq \chi \sqrt{\int_{B(r)} \left[[F(x)]^2 + \sum_{j=1}^n \left(\frac{\partial F}{\partial x_j}\right)^2 \right] dx}. \tag{2}$$

$\chi(1,r) = 1$. Let

$$\nu = \tfrac{1}{2}(n-2), \tag{3}$$

then for $n > 2$,

$$\chi(n,r) = \sqrt{1 + \frac{I_\nu(1)}{I_{\nu+1}(1)} \frac{I_\nu(r)K_{\nu+1}(1) + K_\nu(r)I_{\nu+1}(1)}{I_\nu(r)K_\nu(1) - K_\nu(r)I_\nu(1)}}, \tag{4}$$

where $I_\nu(z)$ is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND and $K_\nu(z)$ is a MODIFIED BESSEL FUNCTION OF THE SECOND KIND. For $n = 2$,

$$\chi(2,r) = \max \left\{ \sqrt{1 + \frac{I_\nu(1)}{I_{\nu+1}(1)} \frac{I_\nu(r)K_{\nu+1}(1) + K_\nu(r)I_{\nu+1}(1)}{I_\nu(r)K_\nu(1) - K_\nu(r)I_\nu(1)}} \sqrt{1 + \frac{I_1(1)}{I_1(1) + I_2(1)} \left[1 + \frac{I_1(r)K_0(1) + K_1(r)I_0(1)}{I_1(r)K_1(1) - K_1(r)I_1(1)} \right]} \right\}. \tag{5}$$

For $r \to \infty$,

$$\chi(n,\infty) = \sqrt{1 + \frac{I_\nu(1)}{I_{\nu+1}(1)} \frac{K_\nu(1)}{K_\nu(1)}}, \tag{6}$$

which is bounded by

$$n - 1 < \chi(n,\infty) < \sqrt{(n-1)^2 + 4}. \tag{7}$$

For ODD n, the RECURRENCE RELATIONS

$$a_{k+1} = a_{k-1} - (2k-1)a_k \tag{8}$$

$$b_{k+1} = b_{k-1} + (2k-1)b_k \tag{9}$$

with

$$a_0 = e + e^{-1} \tag{10}$$

$$a_1 = e - e^{-1} \tag{11}$$

$$b_0 = e^{-1} \tag{12}$$

$$b_1 = e^{-1} \tag{13}$$

where e is the constant 2.71828..., give

$$\chi(2k+1,\infty) = \sqrt{1 + \frac{a_k}{a_{k+1}} \frac{b_{k+1}}{b_k}}. \tag{14}$$

The first few are

$$\chi(3,\infty) = e \tag{15}$$

$$\chi(5,\infty) = \sqrt{\frac{e^2}{e^2 - 7}} \tag{16}$$

$$\chi(7,\infty) = \sqrt{\frac{2}{7}} \sqrt{\frac{e^2}{37 - 5e^2}} \tag{17}$$

$$\chi(9,\infty) = \frac{1}{\sqrt{37}} \sqrt{\frac{e^2}{18e^2 - 133}} \tag{18}$$

$$\chi(11,\infty) = \frac{1}{\sqrt{133}} \sqrt{\frac{e^2}{2431 - 329e^2}} \tag{19}$$

$$\chi(13,\infty) = \sqrt{\frac{2}{2431}} \sqrt{\frac{e^2}{3655e^2 - 27007}}. \tag{20}$$

Similar formulas can be given for even n in terms of $I_0(1)$, $I_1(1)$, $K_0(1)$, $K_1(1)$.

Whitney Singularity

see PINCH POINT

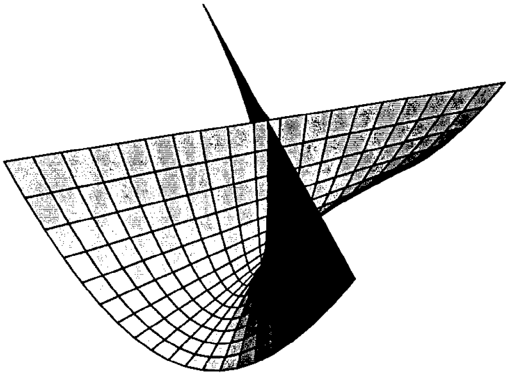
Whitney Sum

An operation that takes two VECTOR BUNDLES over a fixed SPACE and produces a new VECTOR BUNDLE over the same SPACE. If E_1 and E_2 are VECTOR BUNDLES over B, then the Whitney sum $E_1 \oplus E_2$ is the VECTOR BUNDLE over B such that each FIBER over B is naturally the direct sum of the E_1 and E_2 FIBERS over B.

The Whitney sum is therefore the FIBER for FIBER direct sum of the two BUNDLES E_1 and E_2. An easy formal definition of the Whitney sum is that $E_1 \oplus E_2$ is the pull-back BUNDLE of the diagonal map from B to $B \times B$, where the BUNDLE over $B \times B$ is $E_1 \times E_2$.

see also BUNDLE, FIBER, VECTOR BUNDLE

Whitney Umbrella



A surface which can be interpreted as a self-intersecting RECTANGLE in 3-D. It is given by the parametric equations

$$x = uv \qquad (1)$$

$$y = u \qquad (2)$$

$$z = v^2 \qquad (3)$$

for $u, v \in [-1, 1]$. The center of the "plus" shape which is the end of the line of self-intersection is a PINCH POINT. The coefficients of the first FUNDAMENTAL FORM are

$$E = 0 \qquad (4)$$

$$F = \frac{2v}{\sqrt{u^2 + 4v^2 + 4v^4}} \qquad (5)$$

$$G = -\frac{2u}{\sqrt{u^2 + 4v^2 + 4v^4}}, \qquad (6)$$

and the coefficients of the second FUNDAMENTAL FORM are

$$e = 1 + v^2 \qquad (7)$$

$$f = uv \qquad (8)$$

$$g = u^2 + 4v^2, \qquad (9)$$

giving GAUSSIAN CURVATURE and MEAN CURVATURE

$$K = -\frac{4v^2}{(u^2 + 4v^2 + 4v^4)^2} \qquad (10)$$

$$H = -\frac{u(1 + 3v^2)}{(u^2 + 4v^2 + 4v^4)^{3/2}}. \qquad (11)$$

Whittaker Differential Equation

$$\frac{d^2u}{dz^2} + \frac{du}{dz} + \left(\frac{k}{z} + \frac{\frac{1}{4} - m^2}{z^2}\right) u = 0. \qquad (1)$$

Let $u \equiv e^{-z/2} W_{k,m}(z)$, where $W_{k,m}(z)$ denotes a WHITTAKER FUNCTION. Then (1) becomes

$$\frac{d}{dz}(-\tfrac{1}{2}e^{-z/2}W + e^{-z/2}W') + (-\tfrac{1}{2}e^{-z/2}W + e^{-z/2}W') + \left(\frac{k}{z} + \frac{\frac{1}{4} - m^2}{z^2}\right) e^{-z/2}W = 0. \qquad (2)$$

Rearranging,

$$(\tfrac{1}{4}e^{-z/2}W - \tfrac{1}{2}e^{-z/2}W' - \tfrac{1}{2}e^{-z/2}W' + e^{-z/2}W'')p + (-\tfrac{1}{2}e^{-z/2}W + e^{-z/2}W') + \left(\frac{k}{z} + \frac{\frac{1}{4} - m^2}{z^2}\right) e^{-z/2}W = 0 \qquad (3)$$

$$-\tfrac{1}{4}e^{-z/2}W + e^{-z/2}W'' + \left(\frac{k}{z} + \frac{\frac{1}{4} - m^2}{z^2}\right) e^{-z/2}W = 0, \qquad (4)$$

so

$$W'' + \left(-\frac{1}{4} + \frac{k}{z} + \frac{\frac{1}{4} - m^2}{z^2}\right) W = 0, \qquad (5)$$

where $W' \equiv dW/dz$. The solutions are known as WHITTAKER FUNCTIONS.

Abramowitz, M. and Stegun, C. A. (Eds.). *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, 9th printing.* New York: Dover, p. 505, 1972.

Whittaker Function

Solutions to the Whittaker Differential Equation. The linearly independent solutions are

$$M_{k,m}(z) \equiv z^{1/2+m}e^{-z/2} \times \left(1+\frac{\frac{1}{2}+m-k}{1!(2m+1)}+\frac{(\frac{1}{2}+m-k)(\frac{3}{2}+m-k)}{2!(2m+1)(2m+2)}z^2+\ldots\right), \quad (1)$$

and $M_{k,-m}(z)$, where $M_{k,m}(z)$ is a Confluent Hypergeometric Function. In terms of Confluent Hypergeometric Functions, the Whittaker functions are

$$M_{k,m}(z) = e^{-z/2}z^{m+1/2}{}_1F_1(\tfrac{1}{2}+m-k, 1+2m; z) \quad (2)$$

$$W_{k,m}(z) = e^{-z/2}z^{m+1/2}U(\tfrac{1}{2}+m-k, 1+2m; z) \quad (3)$$

(see Whittaker and Watson 1990, pp. 339–351). However, the Confluent Hypergeometric Function disappears when $2m$ is an Integer, so Whittaker functions are often defined instead. The Whittaker functions are related to the Parabolic Cylinder Functions. When $|\arg z| < 3\pi/2$ and $2m$ is not an Integer,

$$W_{k,m}(z) = \frac{\Gamma(-2m)}{\Gamma(\frac{1}{2}-m-k)}M_{k,m}(z) + \frac{\Gamma(2m)}{\Gamma(\frac{1}{2}+m-k)}M_{k,-m}(z). \quad (4)$$

When $|\arg(-z)| < 3\pi/2$ and $2m$ is not an Integer,

$$W_{-k,m}(-z) = \frac{\Gamma(-2m)}{\Gamma(\frac{1}{2}-m-k)}M_{-k,m}(-z) + \frac{\Gamma(2m)}{\Gamma(\frac{1}{2}+m+k)}M_{-k,-m}(-z). \quad (5)$$

Whittaker functions satisfy the Recurrence Relations

$$W_{k,m}(z) = z^{1/2}W_{k-1/2,m-1/2}(z)+(\tfrac{1}{2}-k+m)W_{k-1,m}(z) \quad (6)$$

$$W_{k,m}(z) = z^{1/2}W_{k-1/2,m+1/2}(z)+(\tfrac{1}{2}-k-m)W_{k-1,m}(z) \quad (7)$$

$$zW'_{k,m}(z) = (k-\tfrac{1}{2}z)W_{k,m}(z)-[m^2-(k-\tfrac{1}{2})^2]W_{k-1,m}(z). \quad (8)$$

Whole Number

One of the numbers 1, 2, 3, ... (Sloane's A000027), also called the Counting Numbers or Natural Numbers. 0 is sometimes included in the list of "whole" numbers (Bourbaki 1968, Halmos 1974), but there seems to be no general agreement. Some authors also interpret "whole number" to mean "a number having Fractional Part of zero," making the whole numbers equivalent to the integers.

Due to lack of standard terminology, the following terms are recommended in preference to "Counting Number," "Natural Number," and "whole number."

Set	Name	Symbol
..., −2, −1, 0, 1, 2, ...	integers	$\mathbb{Z}$
1, 2, 3, 4, ...	positive integers	$\mathbb{Z}^+$
0, 1, 2, 3, 4 ...	nonnegative integers	$\mathbb{Z}^*$
−1, −2, −3, −4, ...	negative integers	$\mathbb{Z}^-$

Wiedersehen Manifold

The only Wiedersehen manifolds are the standard round spheres, as was established by proof of the Blaschke Conjecture.

see also Blaschke Conjecture

Wieferich Prime

A Wieferich prime is a Prime p which is a solution to the Congruence equation

$$2^{p-1} \equiv 1 \pmod{p^2}.$$

Note the similarity of this expression to the special case of FERMAT'S LITTLE THEOREM

$$2^{p-1} \equiv 1 \pmod{p},$$

which holds for *all* ODD PRIMES. However, the only Wieferich primes less than 4×10^{12} are $p = 1093$ and 3511 (Lehmer 1981, Crandall 1986, Crandall *et al.* 1997). Interestingly, one less than these numbers have suggestive periodic BINARY representations

$$\begin{aligned} 1092 &= 10001000100_2 \\ 3510 &= 110110110110_2. \end{aligned}$$

A PRIME factor p of a MERSENNE NUMBER $M_q = 2^q - 1$ is a Wieferich prime IFF $p^2 | 2^q - 1$. Therefore, MERSENNE PRIMES are *not* Wieferich primes.

If the first case of FERMAT'S LAST THEOREM is false for exponent p, then p must be a Wieferich prime (Wieferich 1909). If $p | 2^n \pm 1$ with p and n RELATIVELY PRIME, then p is a Wieferich prime IFF p^2 also divides $2^n \pm 1$. The CONJECTURE that there are no three POWERFUL NUMBERS implies that there are infinitely many Wieferich primes (Granville 1986, Vardi 1991). In addition, the ABC CONJECTURE implies that there are at least $C \ln x$ Wieferich primes $\leq x$ for some constant C (Silverman 1988, Vardi 1991).

Wielandt's Theorem

Let the $n \times n$ MATRIX A satisfy the conditions of the PERRON-FROBENIUS THEOREM and the $n \times n$ MATRIX $\mathsf{C} = c_{ij}$ satisfy

$$|c_{ij}| \leq a_{ij}$$

for $i, j = 1, 2, \ldots, n$. Then any EIGENVALUE λ_0 of C satisfies the inequality $|\lambda_0| \leq R$ with the equality sign holding only when there exists an $n \times n$ MATRIX $\mathsf{D} = \delta_{ij}$ (where δ_{ij} is the KRONECKER DELTA) and

$$\mathsf{C} = \frac{\lambda_0}{R} \mathsf{DAD}^{-1}.$$

Wiener Function

see BROWN FUNCTION

Wiener-Khintchine Theorem

Recall the definition of the AUTOCORRELATION function $C(t)$ of a function $E(t)$,

$$C(t) \equiv \int_{-\infty}^{\infty} E^*(\tau) E(t+\tau)\, d\tau. \qquad (1)$$

Also recall that the FOURIER TRANSFORM of $E(t)$ is defined by

$$E(\tau) = \int_{-\infty}^{\infty} E_\nu e^{-2\pi i \nu \tau}\, d\nu, \qquad (2)$$

giving a COMPLEX CONJUGATE of

$$E^*(\tau) = \int_{-\infty}^{\infty} E_\nu^* e^{2\pi i \nu \tau}\, d\nu. \qquad (3)$$

Plugging $E^*(\tau)$ and $E(t+\tau)$ into the AUTOCORRELATION function therefore gives

$$\begin{aligned} C(t) &= \int_{-\infty}^{\infty}\left[\int_{-\infty}^{\infty} E_\nu^* e^{2\pi i\nu\tau}\,d\nu\right] \\ &\quad\times\left[\int_{-\infty}^{\infty} E_{\nu'} e^{-2\pi i\nu'(t+\tau)}\,d\nu'\right] d\tau \\ &= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} E_\nu^* E_{\nu'} e^{-2\pi i\tau(\nu'-\nu)} e^{-2\pi i\nu' t}\,d\tau\,d\nu\,d\nu' \\ &= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} E_\nu^* E_{\nu'}\delta(\nu'-\nu) e^{-2\pi i\nu' t}\,d\nu\,d\nu' \\ &= \int_{-\infty}^{\infty} E_\nu^* E_\nu e^{-2\pi i\nu t}\,d\nu \\ &= \int_{-\infty}^{\infty} |E_\nu|^2 e^{-2\pi i\nu t}\,d\nu \\ &= \mathcal{F}[\,|E_\nu|^2], \end{aligned} \tag{4}$$

so, amazingly, the AUTOCORRELATION is simply given by the FOURIER TRANSFORM of the ABSOLUTE SQUARE of $E(\nu)$,

$$C(t) = \mathcal{F}[|E(\nu)|^2]. \tag{5}$$

The Wiener-Khintchine theorem is a special case of the CROSS-CORRELATION THEOREM with $f = g$.

Wiener Measure

The distribution which arises whenever a central limit scaling procedure is carried out on path-space valued random variables.

Wiener Space

see MALLIAVIN CALCULUS

Wigner 3j-Symbol

The Wigner $3j$ symbols are written

$$\begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & m \end{pmatrix} \tag{1}$$

and are sometimes expressed using the related CLEBSCH-GORDON COEFFICIENTS

$$C^j_{m_1 m_2} = (j_1 j_2 m_1 m_2 | j_1 j_2 j m) \tag{2}$$

(Condon and Shortley 1951, pp. 74–75; Wigner 1959, p. 206), or RACAH V-COEFFICIENTS

$$V(j_1 j_2 j; m_1 m_2 m). \tag{3}$$

Connections among the three are

$$(j_1 j_2 m_1 m_2 | j_1 j_2 m) = (-1)^{-j_1+j_2-m}\sqrt{2j+1}\begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix} \tag{4}$$

$$(j_1 j_2 m_1 m_2 | j_1 j_2 j m) = (-1)^{j+m}\sqrt{2j+1}V(j_1 j_2 j; m_1 m_2\ -m) \tag{5}$$

$$V(j_1 j_2 j; m_1 m_2 m) = (-1)^{-j_1+j_2+j}\begin{pmatrix} j_1 & j_2 & j_1 \\ m_2 & m_1 & m_2 \end{pmatrix}. \tag{6}$$

The Wigner $3j$-symbols have the symmetries

$$\begin{aligned} \begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & m \end{pmatrix} &= \begin{pmatrix} j_2 & j & j_1 \\ m_2 & m & m_1 \end{pmatrix} \\ &= \begin{pmatrix} j & j_1 & j_2 \\ m & m_1 & m_2 \end{pmatrix} = (-1)^{j_1+j_2+j}\begin{pmatrix} j_2 & j_1 & j \\ m_2 & m_1 & m \end{pmatrix} \\ &= (-1)^{j_1+j_2+j}\begin{pmatrix} j_1 & j & j_2 \\ m_1 & m & m_2 \end{pmatrix} \\ &= (-1)^{j_1+j_2+j}\begin{pmatrix} j & j_2 & j_1 \\ m & m_2 & m_1 \end{pmatrix} \\ &= (-1)^{j_1+j_2+j}\begin{pmatrix} j_1 & j_2 & j \\ -m_1 & -m_2 & -m \end{pmatrix}. \end{aligned} \tag{7}$$

The symbols obey the orthogonality relations

$$\sum_{j,m}(2j+1)\begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & m \end{pmatrix}\begin{pmatrix} j_1 & j_2 & j \\ m_1' & m_2' & m \end{pmatrix} = \delta_{m_1 m_1'}\delta_{m_2 m_2'} \tag{8}$$

$$\sum_{m_1, m_2}\begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & m \end{pmatrix}\begin{pmatrix} j_1 & j_2 & j' \\ m_1 & m_2 & m' \end{pmatrix} = \delta_{jj'}\delta_{m_1 m_1'}, \tag{9}$$

where δ_{ij} is the KRONECKER DELTA.

General formulas are very complicated, but some specific cases are

$$\begin{aligned} \begin{pmatrix} j_1 & j_2 & j_1+j_2 \\ m_1 & m_2 & -m_1-m_2 \end{pmatrix} &= (-1)^{j_1-j_2+m_1+m_2} \\ &\quad\times\left[\frac{(2j_1)!(2j_2)!}{(2j_1+2j_2+1)!(j_1+m_1)!}\right. \\ &\quad\left.\times\frac{(j_1+j_2+m_1+m_2)!(j_1+j_2-m_1-m_2)!}{(j_1-m_1)!(j_2+m_2)!(j_2-m_2)!}\right]^{1/2} \end{aligned} \tag{10}$$

$$\begin{aligned} \begin{pmatrix} j_1 & j_2 & j \\ j_1 & -j_1- & m \end{pmatrix} &= (-1)^{-j_1+j_2+m} \\ &\quad\times\left[\frac{(2j_1)!(-j_1+j_2+j)!}{(j_1+j_2+j+1)!(j_1-j_2+j)!}\right. \\ &\quad\left.\frac{(j_1+j_2+m)!(j-m)!}{(j_1+j_2-j)!(-j_1+j_2-m)!(j+m)!}\right]^{1/2} \end{aligned} \tag{11}$$

$$\begin{pmatrix} j_1 & j_2 & j \\ 0 & 0 & 0 \end{pmatrix} = \begin{cases} (-1)^g \sqrt{\frac{(2g-2j_1)!(2g-2j_2)!(2g-2j)!}{(2g+1)!}} \frac{g!}{(g-j_1)!(g-j_2)!(g-j)!} \\ \quad \text{if } J = 2g \\ 0 \\ \quad \text{if } J = 2g+1, \end{cases} \tag{12}$$

for $J \equiv j_1 + j_2 + j$.

For SPHERICAL HARMONICS $Y_{lm}(\theta, \phi)$,

$$Y_{l_1 m_1}(\theta,\phi) Y_{l_2 m_2}(\theta,\phi) = \sum_{l,m} \sqrt{\frac{(2l_1+1)(2l_2+1)(2l+1)}{4\pi}} \begin{pmatrix} l_1 & l_2 & l \\ m_1 & m_2 & m \end{pmatrix} \times Y_{lm}^*(\theta,\psi) \begin{pmatrix} l_1 & l_2 & l \\ 0 & 0 & 0 \end{pmatrix}. \tag{13}$$

For values of l_3 obeying the TRIANGLE CONDITION $\Delta(l_1 l_2 l_3)$,

$$\int Y_{l_1 m_1}(\theta,\phi) Y_{l_2 m_2}(\theta,\phi) Y_{l_3 m_3}(\theta,\phi) \sin\theta \, d\theta \, d\phi = \sqrt{\frac{(2l_1+1)(2l_2+1)(2l_3+1)}{4\pi}} \times \begin{pmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \tag{14}$$

and

$$\frac{1}{2} \int P_{l_1}(\cos\theta) P_{l_2}(\cos\theta) P_{l_3}(\cos\theta) \sin\theta \, d\theta = \begin{pmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{pmatrix}^2. \tag{15}$$

Wigner $6j$-Symbol

A generalization of CLEBSCH-GORDON COEFFICIENTS and WIGNER $3j$-SYMBOL which arises in the coupling of three angular momenta. Let tensor operators $T^{(k)}$ and $U^{(k)}$ act, respectively, on subsystems 1 and 2 of a system, with subsystem 1 characterized by angular momentum $\mathbf{j}_1$ and subsystem 2 by the angular momentum $\mathbf{j}_2$. Then the matrix elements of the scalar product of these two tensor operators in the coupled basis $\mathbf{J} = \mathbf{j}_1 + \mathbf{j}_2$ are given by

$$(\tau_1' j_1' \tau_2' j_2' J' M' | T^{(k)} \cdot U^{(k)} | \tau_1 j_1 \tau_2 j_2 J M) = \delta_{JJ'} \delta_{MM'} (-1)^{j_1 + j_2' + J} \begin{Bmatrix} J & j_2' & j_1' \\ k & j_1 & j_2 \end{Bmatrix} \times (\tau_1' j_1' || T^{(k)} || \tau_1 j_1)(\tau_2' j_2' || U^{(k)} || \tau_2 j_2), \tag{1}$$

where $\begin{Bmatrix} J & j_2' & j_1' \\ k & j_1 & j_2 \end{Bmatrix}$ is the Wigner $6j$-symbol and τ_1 and τ_2 represent additional pertinent quantum numbers characterizing subsystems 1 and 2 (Gordy and Cook 1984).

Edmonds (1968) gives analytic forms of the $6j$-symbol for simple cases, and Shore and Menzel (1968) and Gordy and Cook (1984) give

$$\begin{Bmatrix} a & b & c \\ 0 & c & b \end{Bmatrix} = \frac{(-1)^s}{\sqrt{(2b+1)(2c+1)}} \tag{2}$$

$$\begin{Bmatrix} a & b & c \\ 1 & c & b \end{Bmatrix} = \frac{2(-1)^{s+1} X}{\sqrt{2b(2b+1)(2b+2)2c(2c+1)(2c+2)}} \tag{3}$$

$$\begin{Bmatrix} a & b & c \\ 2 & c & b \end{Bmatrix} = \frac{2(-1)^s [3X(X-1) - 4b(b+1)c(c+1)]}{\sqrt{(2b-1)2b(2b+1)(2b+2)(2b+3)}} \times \frac{1}{\sqrt{(2c-1)2c(2c+1)(2c+2)(2c+3)}}, \tag{4}$$

where

$$s \equiv a + b + c \tag{5}$$

$$X \equiv b(b+1) + c(c+1) - a(a+1). \tag{6}$$

Wigner $9j$-Symbol

A generalization of CLEBSCH-GORDON COEFFICIENTS and WIGNER $3j$- and $6j$-SYMBOLS which arises in the coupling of four angular momenta and can be written in terms of the WIGNER $3j$- and $6j$-SYMBOLS. Let tensor operators $T^{(k_1)}$ and $U^{(k_2)}$ act, respectively, on subsystems 1 and 2. Then the reduced matrix element of the product $T^{(k_1)} \times U^{(k_2)}$ of these two irreducible operators in the coupled representation is given in terms of the reduced matrix elements of the individual operators in the uncoupled representation by

$$\begin{aligned}(\tau'\tau_1'j_1'\tau_2'j_2'J'||[T^{(k_1)} \times U^{(k_2)}]^{(k)}||\tau\tau_1j_1\tau_2j_2J) \\ = \sqrt{(2J+1)(2J'+1)(2k+1)}\sum_{\tau''}\begin{Bmatrix} j_1' & j_1 & k_1 \\ j_2' & j_2 & k_2 \\ J' & J & k \end{Bmatrix} \\ (\tau'\tau_1'j_1'||T^{(k_1)}||\tau''\tau_1j_1)(\tau''\tau_2'j_2'||U^{(k_2)}||\tau\tau_2j_2), \quad (1)\end{aligned}$$

where $\begin{Bmatrix} j_1' & j_1 & k_1 \\ j_2' & j_2 & k_2 \\ J' & J & k \end{Bmatrix}$ is a Wigner $9j$-symbol (Gordy and Cook 1984).

Shore and Menzel (1968) give the explicit formulas

$$\begin{Bmatrix} a & b & C \\ d & e & F \\ G & H & J \end{Bmatrix} = \sum_x (-1)^{2x}(2x+1) \times \begin{Bmatrix} a & b & C \\ F & J & x \end{Bmatrix}\begin{Bmatrix} d & e & F \\ b & x & H \end{Bmatrix}\begin{Bmatrix} G & H & J \\ x & a & d \end{Bmatrix} \quad (2)$$

$$\begin{Bmatrix} a & b & J \\ c & d & J \\ K & K & 0 \end{Bmatrix} = \frac{(-1)^{b+c+J+K}}{\sqrt{(2J+1)(2K+1)}}\begin{Bmatrix} a & b & J \\ d & c & K \end{Bmatrix} \quad (3)$$

$$\begin{Bmatrix} S & S & 1 \\ L & L & 2 \\ J & J & 1 \end{Bmatrix} = \frac{\begin{Bmatrix} S & L & J \\ L & S & 1 \end{Bmatrix}\begin{Bmatrix} J & L & S \\ L & J & 1 \end{Bmatrix}}{5\begin{Bmatrix} 2 & L & L \\ L & 1 & 1 \end{Bmatrix}} + \frac{(-1)^{S+L+J+1}}{15(2L+1)}\frac{\begin{Bmatrix} S & J & L \\ J & S & 1 \end{Bmatrix}}{\begin{Bmatrix} 2 & L & L \\ L & 1 & 1 \end{Bmatrix}}. \quad (4)$$

Wigner-Eckart Theorem

A theorem of fundamental importance in spectroscopy and angular momentum theory which provides both (1) an explicit form for the dependence of all matrix elements of irreducible tensors on the projection quantum numbers and (2) a formal expression of the conservation laws of angular momentum (Rose 1995).

The theorem states that the dependence of the matrix element $(j'm'|T_{LM}|jm)$ on the projection quantum numbers is entirely contained in the WIGNER $3j$-SYMBOL (or, equivalently, the CLEBSCH-GORDON COEFFICIENT), given by

$$(j'm'|T_{LM}|jm) = C(jLj'; mMm')(j'||T_L||j),$$

where $C(jLj'; mMm')$ is a CLEBSCH-GORDON COEFFICIENT and T_{LM} is a set of tensor operators (Rose 1995, p. 85).

Wilbraham-Gibbs Constant

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Let a piecewise smooth function f with only finitely many discontinuities (which are all jumps) be defined on $[-\pi, \pi]$ with FOURIER SERIES

$$a_k = \frac{1}{\pi}\int_{-\pi}^{\pi} f(t)\cos(kt)\,dt \tag{1}$$

$$b_k = \frac{1}{\pi}\int_{-\pi}^{\pi} f(t)\sin(kt)\,dt, \tag{2}$$

$$S_n(f,x) = \tfrac{1}{2}a_0 + \left\{\sum_{k=1}^{n}[a_k\cos(kx) + b_k\sin(kx)]\right\}. \tag{3}$$

Let a discontinuity be at $x = c$, with

$$\lim_{x\to c^-} f(x) > \lim_{x\to c^+} f(x), \tag{4}$$

so

$$D \equiv \left[\lim_{x\to c^-} f(x)\right] - \left[\lim_{x\to c^+} f(x)\right] > 0. \tag{5}$$

Define

$$\phi(c) = \frac{1}{2}\left[\lim_{x\to c^-} f(x) + \lim_{x\to c^+} f(x)\right], \tag{6}$$

and let $x = x_n < c$ be the first local minimum and $x = \xi_n > c$ the first local maximum of $S_n(f,x)$ on either side of x_n. Then

$$\lim_{n\to\infty} S_n(f, x_n) = \phi(c) + \frac{D}{\pi}G' \tag{7}$$

$$\lim_{n\to\infty} S_n(f, \xi_n) = \phi(c) - \frac{D}{\pi}G', \tag{8}$$

where

$$G' \equiv \int_0^{\pi} \operatorname{sinc}\theta\,d\theta = 1.851937052\ldots. \tag{9}$$

Here, $\operatorname{sinc} x \equiv \sin x/x$ is the SINC FUNCTION. The FOURIER SERIES of $y = x$ therefore does not converge to $-\pi$ and π at the ends, but to $-2G'$ and $2G'$. This phenomenon was observed by Wilbraham (1848) and Gibbs (1899). Although Wilbraham was the first to note the phenomenon, the constant G' is frequently (and unfairly) credited to Gibbs and known as the GIBBS CONSTANT. A related constant sometimes also called the GIBBS CONSTANT is

$$G \equiv \frac{2}{\pi}G' = \frac{2}{\pi}\int_0^{\pi} \operatorname{sinc} x\,dx = 1.17897974447216727\ldots \tag{10}$$

(Le Lionnais 1983).

Wilcoxon Rank Sum Test

A nonparametric alternative to the two-sample t-test.

see also PAIRED t-TEST, PARAMETRIC TEST

Wilcoxon Signed Rank Test

A nonparametric alternative to the PAIRED t-TEST which is similar to the FISHER SIGN TEST. This test assumes that there is information in the magnitudes of the differences between paired observations, as well as the signs. Take the paired observations, calculate the differences, and rank them from smallest to largest by ABSOLUTE VALUE. Add all the ranks associated with POSITIVE differences, giving the T_+ statistic. Finally, the P-VALUE associated with this statistic is found from an appropriate table. The Wilcoxon test is an R-ESTIMATE.

Wild Point

For any point P on the boundary of an ordinary BALL, find a NEIGHBORHOOD of P in which the intersection with the BALL's boundary cuts the NEIGHBORHOOD into two parts, each HOMEOMORPHIC to a BALL. A wild point is a point on the boundary that has no such NEIGHBORHOOD.

see also BALL, HOMEOMORPHIC, NEIGHBORHOOD

Wilf-Zeilberger Pair

A pair of CLOSED FORM functions (F, G) is said to be a Wilf-Zeilberger pair if

$$F(n+1,k) - F(n,k) = G(n,k+1) - G(n,k). \tag{1}$$

The Wilf-Zeilberger formalism provides succinct proofs of *known* identities and allows new identities to be discovered whenever it succeeds in finding a proof certificate for a known identity. However, if the starting point is an unknown hypergeometric sum, then the Wilf-Zeilberger method cannot discover a closed form solution, while ZEILBERGER'S ALGORITHM can.

Wilf-Zeilberger pairs are very useful in proving HYPERGEOMETRIC IDENTITIES of the form

$$\sum_k t(n,k) = \mathrm{rhs}(n) \tag{2}$$

for which the SUMMAND $t(n,k)$ vanishes for all k outside some finite interval. Now divide by the right-hand side to obtain

$$\sum_k F(n,k) = 1, \tag{3}$$

where

$$F(n,k) \equiv \frac{t(n,k)}{\mathrm{rhs}(n)}. \quad (4)$$

Now use a RATIONAL FUNCTION $R(n,k)$ provided by ZEILBERGER'S ALGORITHM, define

$$G(n,k) \equiv R(n,k)F(n,k). \quad (5)$$

The identity (1) then results. Summing the relation over all integers then telescopes the right side to 0, giving

$$\sum_k F(n+1,k) = \sum_k F(n,k). \quad (6)$$

Therefore, $\sum_k F(n,k)$ is independent of n, and so must be a constant. If F is properly normalized, then it will be true that $\sum_k F(0,k) = 1$.

For example, consider the BINOMIAL COEFFICIENT identity

$$\sum_k = \sum_{k=0}^{n} \binom{n}{k} = 2^n, \quad (7)$$

the function $R(n,k)$ returned by ZEILBERGER'S ALGORITHM is

$$R(n,k) = \frac{k}{2(k-n-1)}. \quad (8)$$

Therefore,

$$F(n,k) = \binom{n}{k} 2^{-n} \quad (9)$$

and

$$\begin{aligned} G(n,k) \equiv R(n,k)F(n,k) &= \frac{k}{2(k-n-1)}\binom{n}{k}2^{-n} \\ &= -\frac{kn!2^{-n}}{2(n+1-k)k!(n-k)!} = -\binom{n}{k-1}2^{-n-1}. \end{aligned} \quad (10)$$

Taking

$$F(n+1,k) - F(n,k) = G(n,k+1) - G(n,k) \quad (11)$$

then gives the alleged identity

$$\begin{aligned} &\binom{n+1}{k}2^{-n-1} - \binom{n}{k}2^{-n} \\ &\quad = -\binom{n}{k}2^{-n-1} + \binom{n}{k-1}2^{-n-1}? \end{aligned} \quad (12)$$

Expanding and evaluating shows that the identity does actually hold, and it can also be verified that

$$F(0,k) = \binom{0}{k} = \begin{cases} 1 & \text{for } k=0 \\ 0 & \text{otherwise,} \end{cases} \quad (13)$$

so $\sum_k F(0,k) = 1$ (Petkovšek *et al.* 1996, pp. 25–27).

For any Wilf-Zeilberger pair (F,G),

$$\sum_{n=0}^{\infty} G(n,0) = \sum_{n=1}^{\infty}[F(n,n-1) + G(n-1,n-1)] \quad (14)$$

whenever either side converges (Zeilberger 1993). In addition,

$$\sum_{n=0}^{\infty} G(n,0) = \sum_{n=0}^{\infty}\left[F(s(n+1),n) + \sum_{i=0}^{s-1} G(sn+i,n)\right], \quad (15)$$

$$\sum_{k=0}^{\infty} F(0,k) = \sum_{n=0}^{\infty} G(n,0), \quad (16)$$

and

$$\begin{aligned} \sum_{n=0}^{\infty} G(n,0) = \sum_{n=0}^{\infty}\Bigg[&\sum_{j=0}^{t-1} F(s(n+1),tn+j) \\ &+ \sum_{i=0}^{s-1} G(sn+i,tn)\Bigg], \end{aligned} \quad (17)$$

where

$$F_{s,t}(n,k) = \sum_{j=0}^{t-1} F(sn,tk+j) \quad (18)$$

$$G_{s,t}(n,k) = \sum_{i=0}^{s-1} G(sn+i,tk) \quad (19)$$

(Amdeberhan and Zeilberger 1997). The latter identity has been used to compute APÉRY'S CONSTANT to a large number of decimal places (Plouffe).

Wilkie's Theorem

Let $\phi(x_1, \ldots, x_n)$ be an $\mathcal{L}_{\text{exp}}$ formula, where $\mathcal{L}_{\text{exp}} \equiv \mathcal{L} \cup \{e^x\}$ and $\mathcal{L}$ is the language of ordered rings $\mathcal{L} = \{+, -, \cdot, <, 0, 1\}$. Then there are $n \geq m$ and $f_1, \ldots, f_s \in \mathbb{Z}[x_1, \ldots, x_n, e^{x_1}, \ldots, e^{x_n}]$ such that $\phi(x_1, \ldots, x_n)$ is equivalent to

$$\exists x_{m+1} \cdots \exists x_n f_1(x_1, \ldots, x_n, e^{x_1}, \ldots, e^{x_n}) = \ldots$$
$$= f_s(x_1, \ldots, x_n, e^{x_1}, \ldots, e^{x_n}) = 0$$

(Wilkie 1996). In other words, every formula is equivalent to an existential formula and every definable set is the projection of an exponential variety (Marker 1996).

Wilson Plug

A 3-D surface with constant VECTOR FIELD on its boundary which traps at least one trajectory which enters it.

see also VECTOR FIELD

Wilson's Primality Test

see WILSON'S THEOREM

Wilson Prime

A PRIME satisfying

$$W(p) \equiv 0 \pmod{p},$$

where $W(p)$ is the WILSON QUOTIENT, or equivalently,

$$(p-1)! \equiv -1 \pmod{p^2}.$$

5, 13, and 563 are the only Wilson primes less than 5×10^8 (Crandall *et al.* 1997).

Wilson Quotient

$$W(p) \equiv \frac{(p-1)! - 1}{p}.$$

Wilson's Theorem

IFF p is a PRIME, then $(p-1)! + 1$ is a multiple of p, that is

$$(p-1)! \equiv -1 \pmod{p}.$$

This theorem was proposed by John Wilson in 1770 and proved by Lagrange in 1773. Unlike FERMAT'S LITTLE THEOREM, Wilson's theorem is both NECESSARY and SUFFICIENT for primality. For a COMPOSITE NUMBER, $(n-1)! \equiv 0 \pmod{n}$ except when $n = 4$.

Wilson's Theorem Corollary

Iff a PRIME p is of the form $4x+1$, then

$$[(2x)!]^2 \equiv -1 \pmod{p}.$$

Wilson's Theorem (Gauss's Generalization)

Let P be the product of INTEGERS less than or equal to n and RELATIVELY PRIME to n. Then

$$P \equiv \prod_{\substack{k=2 \\ k \nmid n}}^{n} = \begin{cases} -1 \pmod{n} & \text{for } n = 4, p^\alpha, 2p^\alpha \\ 1 \pmod{n} & \text{otherwise.} \end{cases}$$

When $m = 2$, this reduces to $P \equiv 1 \pmod{2}$ which is equivalent to $P \equiv -1 \pmod{2}$.

see also WILSON'S THEOREM, WILSON'S THEOREM COROLLARY

Winding Number (Contour)

Denoted $n(\gamma, z_0)$ and defined as the number of times a path γ curve passes around a point.

$$n(\gamma, a) = \frac{1}{2\pi i} \int_\gamma \frac{dz}{z-a}.$$

The contour winding number was part of the inspiration for the idea of the DEGREE of a MAP between two COMPACT, oriented MANIFOLDS of the same DIMENSION. In the language of the DEGREE of a MAP, if $\gamma : [0,1] \to \mathbb{C}$

is a closed curve (i.e., $\gamma(0) = \gamma(1)$), then it can be considered as a FUNCTION from $\mathbb{S}^1$ to $\mathbb{C}$. In that context, the winding number of γ around a point p in $\mathbb{C}$ is given by the degree of the MAP

$$\frac{\gamma - p}{|\gamma - p|}$$

from the CIRCLE to the CIRCLE.

Winding Number (Map)

The winding number of a map is defined by

$$W \equiv \lim_{n\to\infty} \frac{f^n(\theta) - \theta}{n},$$

which represents the average increase in the angle θ per unit time (average frequency). A system with a RATIONAL winding number $W = p/q$ is MODE-LOCKED, whereas a system with an IRRATIONAL winding number is QUASIPERIODIC. Note that since the RATIONALS are a set of zero MEASURE on any finite interval, almost all winding numbers will be irrational, so almost all maps will be QUASIPERIODIC.

Windmill

One name for the figure used by Euclid to prove the PYTHAGOREAN THEOREM.

see BRIDE'S CHAIR, PEACOCK'S TAIL

Window Function

see RECTANGLE FUNCTION

Winkler Conditions

Conditions arising in the study of the ROBBINS EQUATION and its connection with BOOLEAN ALGEBRA. Winkler studied Boolean conditions (such as idempotence or existence of a zero) which would make a ROBBINS ALGEBRA become a BOOLEAN ALGEBRA. Winkler showed that each of the conditions

$$\exists C, \exists D, C + D = C$$

$$\exists C, \exists D, n(C + D) = n(C),$$

known as the first and second Winkler conditions, SUFFICES. A computer proof demonstrated that every ROBBINS ALGEBRA satisfies the second Winkler condition, from which it follows immediately that all ROBBINS ALGEBRAS are BOOLEAN.

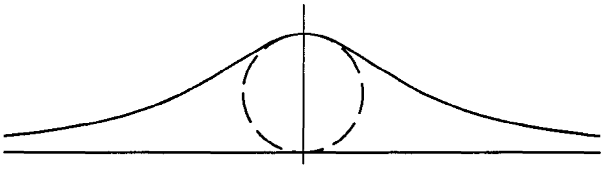
Witch of Agnesi



A curve studied and named "versiera" (Italian for "she-devil" or "witch") by Maria Agnesi in 1748 in her book *Istituzioni Analitiche* (MacTutor Archive). It is also known as CUBIQUE D'AGNESI or AGNÉSIENNE. Some suggest that Agnesi confused an old Italian word meaning "free to move" with another meaning "witch." The curve had been studied earlier by Fermat and Guido Grandi in 1703.

It is the curve obtained by drawing a line from the origin through the CIRCLE of radius $2a$ (OB), then picking the point with the y coordinate of the intersection with the circle and the x coordinate of the intersection of the extension of line OB with the line $y = 2a$. The curve has INFLECTION POINTS at $y = 3a/2$. The line $y = 0$ is an ASYMPTOTE to the curve.

In parametric form,

$$x = 2a \cot \theta \tag{1}$$
$$y = a[1 - \cos(2\theta)], \tag{2}$$

or

$$x = 2at \tag{3}$$
$$y = \frac{2a}{1+t^2}. \tag{4}$$

In rectangular coordinates,

$$y = \frac{8a^3}{x^2 + 4a^2}. \tag{5}$$

Witness

A witness is a number which, as a result of its number theoretic properties, guarantees either the compositeness or primality of a number n. Witnesses are most commonly used in connection with FERMAT'S LITTLE THEOREM CONVERSE. A PRATT CERTIFICATE uses witnesses to prove primality, and MILLER'S PRIMALITY TEST uses witnesses to prove compositeness.

see also ADLEMAN-POMERANCE-RUMELY PRIMALITY TEST, FERMAT'S LITTLE THEOREM CONVERSE, MILLER'S PRIMALITY TEST, PRATT CERTIFICATE, PRIMALITY CERTIFICATE

Witten's Equations

Also called the SEIBERG-WITTEN INVARIANTS. For a connection A and a POSITIVE SPINOR $\phi \in \Gamma(V_+)$,

$$D_A\phi = 0$$
$$F_+^A = i\sigma(\phi, \phi).$$

The solutions are called monopoles and are the minima of the functional

$$\int_X (|F_+^A - i\sigma(\phi,\phi)|^2 + |D_A\phi|^2).$$

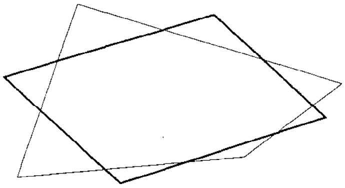
Wittenbauer's Parallelogram



Divide the sides of a QUADRILATERAL into three equal parts. The figure formed by connecting and extending adjacent points on either side of a VERTEX is a PARALLELOGRAM known as Wittenbauer's parallelogram.

see also QUADRILATERAL, WITTENBAUER'S THEOREM

Wittenbauer's Theorem

The CENTROID of a QUADRILATERAL LAMINA is the center of its WITTENBAUER'S PARALLELOGRAM.

see also CENTROID (GEOMETRIC), LAMINA, QUADRILATERAL, WITTENBAUER'S PARALLELOGRAM

Wolstenholme's Theorem

If p is a PRIME > 3, then the NUMERATOR of

$$1 + \tfrac{1}{2} + \tfrac{1}{3} + \ldots + \tfrac{1}{p-1}$$

is divisible by p^2 and the NUMERATOR of

$$1 + \frac{1}{2^2} + \frac{1}{3^2} + \ldots + \frac{1}{(p-1)^2}$$

is divisible by p. These imply that if $p \geq 5$ is PRIME, then

$$\binom{2p-1}{p-1} \equiv 1 \pmod{p^3}.$$

Woodbury Formula

$$(\mathsf{A}+\mathsf{U}\mathsf{V}^{\mathrm{T}})^{-1} = \mathsf{A}^{-1} - [\mathsf{A}^{-1}\mathsf{U}(1+\mathsf{V}^{\mathrm{T}}\mathsf{A}^{-1}\mathsf{U})^{-1}\mathsf{V}^{\mathrm{T}}\mathsf{A}^{-1}].$$

Word

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

A finite sequence of n letters from some ALPHABET is said to be an n-ary word. A "square" word consists of two identical subwords (for example, *acbacb*). A squarefree word contains *no* square words as subwords (for example, *abcacbabcb*). The only squarefree binary words are *a*, *b*, *ab*, *ba*, *aba*, and *bab*. However, there are arbitrarily long ternary squarefree words. The number of ternary squarefree words of length n is bounded by

$$6 \cdot 1.032^n \leq s(n) \leq 6 \cdot 1.379^n \tag{1}$$

(Brandenburg 1983). In addition,

$$S \equiv \lim_{n\to\infty} [s(n)]^{1/n} = 1.302\ldots \tag{2}$$

(Brinkhuis 1983, Noonan and Zeilberger). Binary cubefree words satisfy

$$2 \cdot 1.080^n \leq c(n) \leq 2 \cdot 1.522^n. \tag{3}$$

A word is said to be overlapfree if it has no subwords of the form *xyxyx*. A squarefree word is overlapfree, and an overlapfree word is cubefree. The number $t(n)$ of binary overlapfree words of length n satisfies

$$p \cdot n^{1.155} \leq t(n) \leq q \cdot n^{1.587} \tag{4}$$

for some constants p and q (Restivo and Selemi 1985, Kobayashi 1988). In addition, while

$$\lim_{n\to\infty} \frac{\ln t(n)}{\ln n} \tag{5}$$

does not exist,

$$1.155 < T_L < 1.276 < 1.332 < T_U < 1.587, \tag{6}$$

where

$$T_L \equiv \liminf_{n\to\infty} \frac{\ln t(n)}{\ln n} \tag{7}$$

$$T_U \equiv \limsup_{n\to\infty} \frac{\ln t(n)}{\ln n} \tag{8}$$

(Cassaigne 1993).

Worpitzky's Identity

$$x^n = \sum_{k=0}^{n-1} \left\langle {n \atop k} \right\rangle \binom{n+k}{n},$$

where $\left\langle {n \atop k} \right\rangle$ is an EULERIAN NUMBER and $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

Writhe

Also called the TWIST NUMBER. The sum of crossings p of a LINK L,

$$w(L) = \sum_{p \in C(L)} \epsilon(p),$$

where $\epsilon(p)$ defined to be ± 1 if the overpass slants from top left to bottom right or bottom left to top right and $C(L)$ is the set of crossings of an oriented LINK. If a KNOT K is AMPHICHIRAL, then $w(K) = 0$ (Thistlethwaite). Letting Lk be the LINKING NUMBER of the two components of a ribbon, Tw be the TWIST, and Wr be the writhe, then

$$\mathrm{Lk}(K) = \mathrm{Tw}(K) + \mathrm{Wr}(K).$$

(Adams 1994, p. 187).

Wythoff Symbol

A symbol used to describe UNIFORM POLYHEDRA. For example, the Wythoff symbol for the TETRAHEDRON is $3 \,|\, 2\,3$. There are three types of Wythoff symbols $p \,|\, q\, r$, $p\, q \,|\, r$ and $p\, q\, r \,|$, and one exceptional symbol $|\, \frac{3}{2}\, \frac{5}{3}\, 3\, \frac{5}{2}$ used for the GREAT DIRHOMBICOSIDODECAHEDRON. Some special cases in terms of SCHLÄFLI SYMBOLS are

$$p \,|\, q\, 2 = p \,|\, 2\, q = \{q, p\}$$

$$2 \,|\, p\, q = \begin{Bmatrix} p \\ q \end{Bmatrix}$$

$$p\, q \,|\, 2 = r \begin{Bmatrix} p \\ q \end{Bmatrix}$$

$$2\, q \,|\, p = \mathrm{t}\{p, q\}$$

$$2\, p\, q \,| = \mathrm{t} \begin{Bmatrix} p \\ q \end{Bmatrix}$$

$$|\, 2\, p\, q = \mathrm{s} \begin{Bmatrix} p \\ q \end{Bmatrix}.$$

For the symbol $p\, q\, r \,|$, permuting the letters gives the same POLYHEDRON.

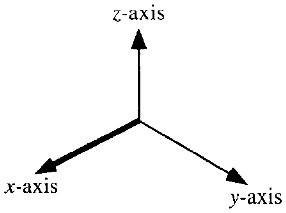
X

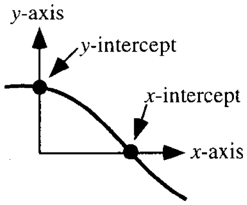
x-Axis



The horizontal axis of a 2-D plot in CARTESIAN COORDINATES, also called the ABSCISSA.

see also ABSCISSA, ORDINATE, y-AXIS, z-AXIS

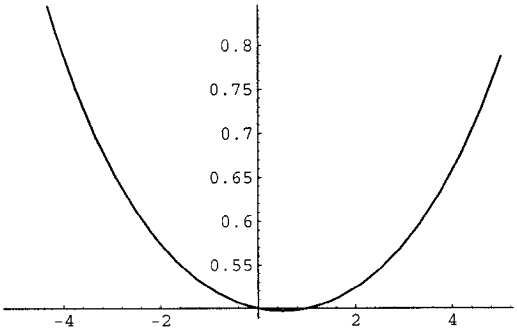
x-Intercept

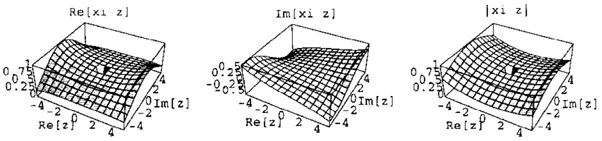


The point at which a curve or function crosses the x-AXIS (i.e., when $y = 0$ in 2-D).

see also LINE, y-INTERCEPT

Xi Function





$$\xi(z) \equiv \tfrac{1}{2}z(z-1)\frac{\Gamma(\frac{1}{2}z)}{\pi^{z/2}}\zeta(z) = \frac{(z-1)\Gamma(\frac{1}{2}z+1)\zeta(z)}{\sqrt{\pi^z}}, \tag{1}$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION and $\Gamma(z)$ is the GAMMA FUNCTION (Gradshteyn and Ryzhik 1980, p. 1076). The ξ function satisfies the identity

$$\xi(1-z) = \xi(z). \tag{2}$$

The zeros of $\xi(z)$ and of its DERIVATIVES are all located on the CRITICAL STRIP $z = \sigma + it$, where $0 < \sigma < 1$. Therefore, the nontrivial zeros of the RIEMANN ZETA FUNCTION exactly correspond to those of $\xi(z)$. The function $\xi(z)$ is related to what Gradshteyn and Ryzhik (1980, p. 1074) call $\Xi(t)$ by

$$\Xi(t) \equiv \xi(z), \tag{3}$$

where $z \equiv \frac{1}{2} + it$. This function can also be defined as

$$\Xi(it) \equiv \tfrac{1}{2}(t^2 - \tfrac{1}{4})\pi^{-t/2-1/4}\Gamma(\tfrac{1}{2}t + \tfrac{1}{4})\zeta(t + \tfrac{1}{2}), \tag{4}$$

giving

$$\Xi(t) = -\tfrac{1}{2}(t^2 + \tfrac{1}{4})\pi^{it/2-1/4}\Gamma(\tfrac{1}{4} - \tfrac{1}{2}it)\zeta(\tfrac{1}{2} - it). \tag{5}$$

The DE BRUIJN-NEWMAN CONSTANT is defined in terms of the $\Xi(t)$ function.

see also DE BRUIJN-NEWMAN CONSTANT

Yanghui Triangle

see PASCAL'S TRIANGLE

Yff Center of Congruence

Let three ISOSCELIZERS, one for each side, be constructed on a TRIANGLE such that the four interior triangles they determine are congruent. Now parallel-displace these ISOSCELIZERS until they concur in a single point. This point is called the Yff center of congruence and has TRIANGLE CENTER FUNCTION

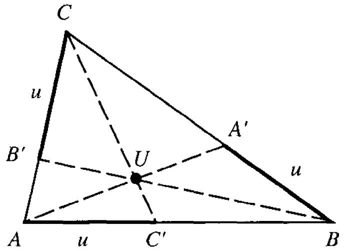
$$\alpha = \sec(\tfrac{1}{2}A).$$

see also CONGRUENT ISOSCELIZERS POINT, ISOSCELIZER

References

Kimberling, C. "Yff Center of Congruence." `http://www.evansville.edu/~ck6/tcenters/recent/yffcc.html`.

Yff Points



Let points A', B', and C' be marked off some fixed distance x along each of the sides BC, CA, and AB. Then the lines AA', BB', and CC' concur in a point U known as the first Yff point if

$$x^3 = (a - x)(b - x)(c - x). \tag{1}$$

This equation has a single real root u, which can by obtained by solving the CUBIC EQUATION

$$f(x) = 2x^3 - px^2 + qx - r = 0, \tag{2}$$

where

$$p = a + b + c \tag{3}$$

$$q = ab + ac + bc \tag{4}$$

$$r = abc. \tag{5}$$

The ISOTOMIC CONJUGATE POINT U' is called the second Yff point. The TRIANGLE CENTER FUNCTIONS of the first and second points are given by

$$\alpha = \frac{1}{a}\left(\frac{c-u}{b-u}\right)^{1/3} \tag{6}$$

and

$$\alpha' = \frac{1}{a}\left(\frac{b-u}{c-u}\right)^{1/3}, \tag{7}$$

respectively. Analogous to the inequality $\omega \leq \pi/6$ for the BROCARD ANGLE ω, $u \leq p/6$ holds for the Yff points, with equality in the case of an EQUILATERAL TRIANGLE. Analogous to

$$\omega < \alpha_i < \pi - 3\omega \tag{8}$$

for $i = 1, 2, 3$, the Yff points satisfy

$$u < a_i < p - 3u. \tag{9}$$

Yff (1963) gives a number of other interesting properties. The line UU' is PERPENDICULAR to the line containing the INCENTER I and CIRCUMCENTER O, and its length is given by

$$\overline{UU'} = \frac{4u\overline{IO}\Delta}{u^3 + abc}, \tag{10}$$

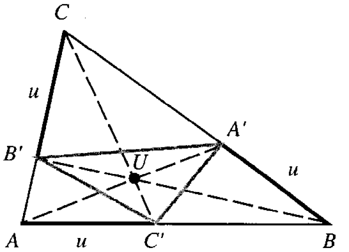
where Δ is the AREA of the TRIANGLE.

see also BROCARD POINTS, YFF TRIANGLES

References

Yff, P. "An Analog of the Brocard Points." *Amer. Math. Monthly* **70**, 495–501, 1963.

Yff Triangles



The TRIANGLE $\Delta A'B'C'$ formed by connecting the points used to construct the YFF POINTS is called the first Yff triangle. The AREA of the triangle is

$$\Delta = \frac{u^3}{2R},$$

where R is the CIRCUMRADIUS of the original TRIANGLE ΔABC. The second Yff triangle is formed by connecting the ISOTOMIC CONJUGATE POINTS of A', B', and C'.

see also YFF POINTS

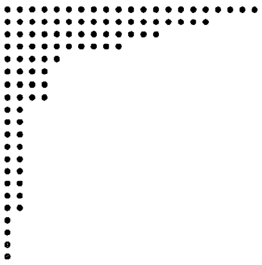
Young Diagram



A Young diagram, also called a FERRERS DIAGRAM, represents PARTITIONS as patterns of dots, with the nth row having the same number of dots as the nth term in the PARTITION. A Young diagram of the PARTITION

$$n = a + b + \ldots + c,$$

for a list $a, b, \ldots, c$ of k POSITIVE INTEGERS with $a \geq b \geq \ldots \geq c$ is therefore the arrangement of n dots or square boxes in k rows, such that the dots or boxes are left-justified, the first row is of length a, the second row is of length b, and so on, with the kth row of length c. The above diagram corresponds to one of the possible partitions of 100.

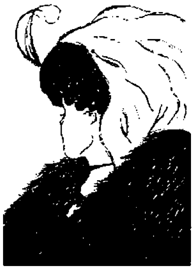
Young Girl-Old Woman Illusion



A perceptual ILLUSION in which the brain switches between seeing a young girl and an old woman.

see also RABBIT-DUCK ILLUSION

References
Pappas, T. *The Joy of Mathematics.* San Carlos, CA: Wide World Publ./Tetra, p. 173, 1989.

Young Inequality

For $0 < p < 1$,

$$ab \leq \frac{a^p}{p} + \left(1 - \frac{1}{p}\right) b^{1/(1-1/p)}.$$

Young's Integral

Let $f(x)$ be a REAL continuous monotonic strictly increasing function on the interval $[0, a]$ with $f(0) = 0$ and $b \leq f(a)$, then

$$ab \leq \int_0^a f(x)\,dx + \int_0^b f^{-1}(y)\,dy,$$

where $f^{-1}(y)$ is the INVERSE FUNCTION. Equality holds IFF $b = f(a)$.

References
Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products, 5th ed.* San Diego, CA: Academic Press, p. 1099, 1979.

Young Tableau

The YOUNG TABLEAU of a YOUNG DIAGRAM is obtained by placing the numbers 1, ..., n in the n boxes of the diagram. A "standard" Young tableau is a Young tableau in which the numbers form a nondecreasing sequence along each line and along each column. The standard Young tableaux of size three are given by $\{\{1,2,3\}\}$, $\{\{1,3\},\{2\}\}$, $\{\{1,2\},\{3\}\}$, and $\{\{1\},\{2\},\{3\}\}$. The number of standard Young tableaux of size 1, 2, 3, ... are 1, 2, 4, 10, 26, 76, 232, 764, 2620, 9496, ... (Sloane's A000085). These numbers can be generated by the RECURRENCE RELATION

$$a(n) = a(n-1) + (n-1)a(n-2)$$

with $a(1) = 1$ and $a(2) = 2$.

There is a correspondence between a PERMUTATION and a pair of Young tableaux, known as the SCHENSTED CORRESPONDENCE. The number of all standard Young tableaux with a given shape (corresponding to a given YOUNG DIAGRAM) is calculated with the HOOK LENGTH FORMULA. The BUMPING ALGORITHM is used to construct a standard Young tableau from a permutation of $\{1, \ldots, n\}$.

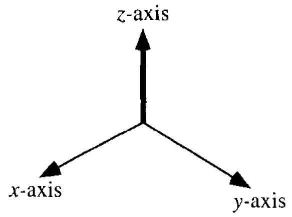
z-Axis



The axis in 3-D CARTESIAN COORDINATES which is usually oriented vertically. CYLINDRICAL COORDINATES are defined such that the *z*-axis is the axis about which the azimuthal coordinate θ is measured.

see also AXIS, *x*-AXIS, *y*-AXIS

z-Distribution

see FISHER'S *z*-DISTRIBUTION, STUDENT'S *z*-DISTRIBUTION

Z-Number

A *Z*-number is a REAL NUMBER ξ such that

$$0 \le \operatorname{frac}\left[\left(\frac{3}{2}\right)^k \xi\right] < \tfrac{1}{2}$$

for all $k = 1, 2, \ldots$, where $\operatorname{frac}(x)$ is the fractional part of x. Mahler (1968) showed that there is at most one *Z*-number in each interval $[n, n+1)$ for integral n. Mahler (1968) therefore concluded that it is unlikely that any *Z*-numbers exist. The *Z*-numbers arise in the analysis of the COLLATZ PROBLEM.

see also COLLATZ PROBLEM

z-Score

The *z*-score associated with the *i*th observation of a random variable x is given by

$$z_i \equiv \frac{x_i - \bar{x}}{\sigma},$$

where $\bar{x}$ is the MEAN and σ the STANDARD DEVIATION of all observations $x_1, \ldots, x_n$.

z-Transform

The discrete *z*-transform is defined as

$$\mathcal{Z}[a] = \sum_{n=0}^{N-1} a_n z^{kn}. \tag{1}$$

The DISCRETE FOURIER TRANSFORM is a special case of the *z*-transform with

$$z \equiv e^{-2\pi i/N}. \tag{2}$$

A *z*-transform with

$$z \equiv e^{-2\pi i\alpha/N} \tag{3}$$

for $\alpha \neq \pm 1$ is called a FRACTIONAL FOURIER TRANSFORM.

see also DISCRETE FOURIER TRANSFORM, FRACTIONAL FOURIER TRANSFORM

References

Arndt, J. "The *z*-Transform (ZT)." Ch. 3 in "Remarks on FFT Algorithms." `http://www.jjj.de/fxt/`.

z-Transform (Population)

see POPULATION COMPARISON

Z-Transform

The *Z*-transform of $F(t)$ is defined by

$$Z[F(t)] = \mathcal{L}[F^*(t)], \tag{1}$$

where

$$F^*(t) = F(t)\delta_T(t) = \sum_{n=0}^{\infty} F(nT)\delta(t - nT), \tag{2}$$

$\delta(t)$ is the DELTA FUNCTION, T is the sampling period, and $\mathcal{L}$ is the LAPLACE TRANSFORM. An alternative definition is

$$Z[F(t)] = \sum_{\text{residues}} \left(\frac{1}{1-e^{Tz}z^{-1}}\right) f(z), \tag{3}$$

where

$$f(z) = \sum_{n=0}^{\infty} F(nT)z^{-n}. \tag{4}$$

The inverse Z-transform is

$$Z^{-1}[f(z)] = F^{*}(t) = \frac{1}{2\pi i}\oint f(z)z^{n-1}\,dz. \tag{5}$$

It satisfies

$$Z[aF(t)+bG(t)] = aZ[F(t)]+bZ[F(t)] \tag{6}$$
$$Z[F(t+T)] = zZ[F(t)] - zF(0) \tag{7}$$
$$Z[F(t+2T)] = z^2Z[F(t)] - z^2F(0) - zF(t) \tag{8}$$
$$Z[F(t+mT)] = z^mZ[F(t)] - \sum_{r=0}^{m-1} z^{m-r}F(rt) \tag{9}$$
$$Z[F(t-mT)] = z^{-m}Z[F(t)] \tag{10}$$
$$Z[e^{at}F(t)] = Z[e^{-aT}z] \tag{11}$$
$$Z[e^{-at}F(t)] = Z[e^{aT}z] \tag{12}$$
$$tF(t) = -Tz\frac{d}{dz}Z[F(t)] \tag{13}$$
$$t^{-1}F(t) = -\frac{1}{T}\int_0^z \frac{f(z)}{z}\,dz. \tag{14}$$

Transforms of special functions (Beyer 1987, pp. 426–427) include

$$Z[\delta(t)] = 1 \tag{15}$$
$$Z[\delta(t-mT)] = z^{-m} \tag{16}$$
$$Z[H(t)] = \frac{z}{z-1} \tag{17}$$
$$Z[H(t-mT)] = \frac{z}{z^m(z-1)} \tag{18}$$
$$Z[t] = \frac{Tz}{(z-1)^2} \tag{19}$$
$$Z[t^2] = \frac{T^2z(z+1)}{(z-1)^3} \tag{20}$$
$$Z[t^3] = \frac{T^3z(z^2+4z+1)}{(z-1)^4} \tag{21}$$
$$Z[a^{\omega t}] = \frac{z}{z-a^{\omega T}} \tag{22}$$
$$Z[\cos(\omega t)] = \frac{z\sin(\omega T)}{z^2-2z\cos(\omega T)+1} \tag{23}$$
$$Z[\sin(\omega t)] = \frac{z[z-\cos(\omega T)]}{z^2-2z\cos(\omega T)+1}, \tag{24}$$

where $H(t)$ is the HEAVISIDE STEP FUNCTION. In general,

$$Z[t^n] = (-1)^n \lim_{x\to 0}\frac{\partial^n}{\partial x^n}\left(\frac{z}{z-e^{-xT}}\right) \tag{25}$$
$$= \frac{T^n z \sum_{k=1}^{n} \left\langle {n \atop k} \right\rangle z^{k-1}}{(z-1)^{n+1}}, \tag{26}$$

where the $\left\langle {n \atop k} \right\rangle$ are EULERIAN NUMBERS. Amazingly, the Z-transforms of t^n are therefore generators for EULER'S TRIANGLE.

see also EULER'S TRIANGLE, EULERIAN NUMBER

Zarankiewicz's Conjecture

The CROSSING NUMBER for a COMPLETE BIGRAPH is

$$\left\lfloor\frac{n}{2}\right\rfloor \left\lfloor\frac{n-1}{2}\right\rfloor \left\lfloor\frac{m}{2}\right\rfloor \left\lfloor\frac{m-1}{2}\right\rfloor,$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION. This has been shown to be true for all $m, n \leq 7$. Zarankiewicz has shown that, in general, the FORMULA provides an upper bound to the actual number.

see also COMPLETE BIGRAPH, CROSSING NUMBER (GRAPH)

Zariski Topology

A TOPOLOGY of an infinite set whose OPEN SETS have finite complements.

Zaslavskii Map

The 2-D map

$$x_{n+1} = [x_n + \nu(1+\mu y_n) + \epsilon\nu\mu\cos(2\pi x_n)] \pmod 1$$
$$y_{n+1} = e^{-\Gamma}[y_n + \epsilon\cos(2\pi x_n)],$$

where

$$\mu \equiv \frac{1-e^{-\Gamma}}{\Gamma}$$

(Zaslavskii 1978). It has CORRELATION EXPONENT $\nu \approx 1.5$ (Grassberger and Procaccia 1983) and CAPACITY DIMENSION 1.39 (Russell *et al.* 1980).

Zassenhaus-Berlekamp Algorithm

A method for factoring POLYNOMIALS.

Zeckendorf Representation

A number written as a sum of nonconsecutive FIBONACCI NUMBERS,

$$n=\sum_{k=0}^{L}\epsilon_k F_k,$$

where ϵ_k are 0 or 1 and

$$\epsilon_k\epsilon_{k+1}=0.$$

Every POSITIVE INTEGER can be written uniquely in such a form.

Zeilberger's Algorithm

An ALGORITHM which finds a POLYNOMIAL recurrence for a terminating HYPERGEOMETRIC IDENTITIES of the form

$$\sum_k \binom{n}{k}\frac{\prod_{i=1}^{A}(a_in+a_i'k+a_i'')!}{\prod_{i=1}^{B}(b_in+b_i'k+b_i'')!}z_k \\ =C\frac{\prod_{i=1}^{\bar A}(\bar a_in+\bar a_i')!}{\prod_{i=1}^{\bar B}(\bar b_in+\bar b_i')}\bar x^n,$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, a_i, a_i', $\bar a_i$, b_i, b_i', $\bar b_i$ are constant integers and a_i'', $\bar a_i'$, b_i'', $\bar b_i'$, C, x, and z are complex numbers (Zeilberger 1990). The method was called CREATIVE TELESCOPING by van der Poorten (1979), and led to the development of the amazing machinery of WILF-ZEILBERGER PAIRS.

Zeisel Number

A number $N = p_1p_2\cdots p_k$ (where the p_is are distinct PRIMES) such that

$$p_n = Ap_{n-1} + B,$$

with A and B constants and $p_0 \equiv 1$. For example, $1885 = 1\cdot 5\cdot 13\cdot 29$ and $114985 = 1\cdot 5\cdot 13\cdot 29\cdot 61$ are Zeisel numbers with $(A, B) = (2, 3)$.

Zeno's Paradoxes

A set of four PARADOXES dealing with counterintuitive aspects of continuous space and time.

1. Dichotomy paradox: Before an object can travel a given distance d, it must travel a distance $d/2$. In order to travel $d/2$, it must travel $d/4$, etc. Since this sequence goes on forever, it therefore appears that the distance d cannot be traveled. The resolution of the paradox awaited CALCULUS and the proof that infinite GEOMETRIC SERIES such as $\sum_{i=1}^{\infty}(1/2)^i = 1$ can converge, so that the infinite number of "half-steps" needed is balanced by the increasingly short amount of time needed to traverse the distances.
2. Achilles and the tortoise paradox: A fleet-of-foot Achilles is unable to catch a plodding tortoise which has been given a head start, since during the time it takes Achilles to catch up to a given position, the tortoise has moved forward some distance. But this is obviously fallacious since Achilles will clearly pass the tortoise! The resolution is similar to that of the dichotomy paradox.
3. Arrow paradox: An arrow in flight has an instantaneous position at a given instant of time. At that instant, however, it is indistinguishable from a motionless arrow in the same position, so how is the motion of the arrow perceived?
4. Stade paradox: A paradox arising from the assumption that space and time can be divided only by a definite amount.

Zermelo's Axiom of Choice

see AXIOM OF CHOICE

Zermelo-Fraenkel Axioms

The Zermelo-Fraenkel axioms are the basis for ZERMELO-FRAENKEL SET THEORY. In the following, $\exists$ stands for EXISTS, $\in$ for "is an element of," $\forall$ for FOR ALL, $\Rightarrow$ for IMPLIES, $\neg$ for NOT (NEGATION), $\land$ for AND, $\lor$ for OR, $\rightleftharpoons$ for "is EQUIVALENT to," and $\mathcal{S}$ denotes the union y of all the sets that are the elements of x.

1. Existence of the empty set: $\exists x\forall u\neg(u\in x)$.
2. Extensionality axiom: $\forall x\forall y(\forall u(u\in x \rightleftharpoons u\in y)\to x=y)$.
3. Unordered pair axiom: $\forall x\forall y\exists z\forall u(u\in z\rightleftharpoons u=x\lor u=y)$.
4. Union (or "sum-set") axiom: $\forall x\exists y\forall u(u\in y\rightleftharpoons \exists v(u\in v\land v\in x))$.
5. Subset axiom: $\forall x\exists y\forall u(u\in y\rightleftharpoons\forall v(v\in u\to v\in x))$.
6. Replacement axiom: For any set-theoretic formula $A(u,v)$,
$$\begin{aligned}&\forall u\forall v\forall w(A(u,v)\land A(u,w)\to v=w)\\&\qquad\to\forall x\exists y\forall v(v\in y\rightleftharpoons\exists u(u\in x\land A(u,v))).\end{aligned}$$
7. Regularity axiom: For any set-theoretic formula $A(u)$, $\exists x A(x)\to\exists x(A(x)\land\neg\exists y(A(y)\land y\in x))$.
8. AXIOM OF CHOICE:
$$\begin{aligned}&\forall x[\forall u(u\in x\to\exists v(v\in u))\\&\qquad\land\forall u\forall v((u\in x\land v\in x\land\neg u=v)\\&\quad\to\neg\exists w(w\in u\land w\in v))\to\exists y\{y\subset\mathcal{S}(x)\\&\qquad\land\forall u(u\in x\to\exists z(z\in u\land z\in y\\&\qquad\qquad\land\forall w(w\in u\land w\in y\to w=z)))\}]\end{aligned}$$
9. Infinity axiom: $\exists x(\exists u(u\in x)\land\forall u(u\in x\to\exists v(v\in x\land u\subset v\land\neg v=u)))$.

If Axiom 6 is replaced by

6'. Axiom of subsets: for any set-theoretic formula $A(u)$, $\forall x\exists y\forall u(u\in y\rightleftharpoons u\in x\land A(u))$,

which can be deduced from Axiom 6, then the set theory is called ZERMELO SET THEORY instead of ZERMELO-FRAENKEL SET THEORY.

Abian (1969) proved CONSISTENCY and independence of four of the Zermelo-Fraenkel axioms.

Zernike Polynomial

ORTHOGONAL POLYNOMIALS which arise in the expansion of a wavefront function for optical systems with circular pupils. The ODD and EVEN Zernike polynomials are given by

$$\begin{matrix} {}^oU_n^m(\rho,\phi) \\ {}^eU_n^m(\rho,\phi) \end{matrix} = R_n^m(\rho) \begin{matrix} \sin \\ \cos \end{matrix} (m\phi) \tag{1}$$

with radial function

$$R_n^m(\rho) = \sum_{l=0}^{(n-m)/2} \frac{(-1)^l (n-l)!}{l![\frac{1}{2}(n+m)-l]![\frac{1}{2}(n-m)-l]!} \rho^{n-2l} \tag{2}$$

for n and m integers with $n \geq m \geq 0$ and $n-m$ EVEN. Otherwise,

$$R_n^m(\rho) = 0. \tag{3}$$

Here, ϕ is the azimuthal angle with $0 \leq \phi < 2\pi$ and ρ is the radial distance with $0 \leq \rho \leq 1$ (Prata and Rusch 1989). The radial functions satisfy the orthogonality relation

$$\int_0^1 R_n^m(\rho) R_{n'}^m(\rho) \rho \, d\rho = \frac{1}{2(n+1)} \delta_{nn'}, \tag{4}$$

where δ_{ij} is the KRONECKER DELTA, and are related to the BESSEL FUNCTION OF THE FIRST KIND by

$$\int_0^1 R_n^m(\rho) J_m(v\rho) \rho \, d\rho = (-1)^{(n-m)/2} \frac{J_{n+1}(v)}{v} \tag{5}$$

(Born and Wolf 1989, p. 466). The radial Zernike polynomials have the GENERATING FUNCTION

$$\frac{[1+z-\sqrt{1-2z(1-2\rho^2)+z^2}\,]^m}{(2z\rho)^m \sqrt{1-2z(1-2\rho^2)+z^2}} = \sum_{s=0}^{\infty} z^s R_{m+2s}^{\pm m}(\rho), \tag{6}$$

and are normalized so that

$$R_n^{\pm m}(1) = 1 \tag{7}$$

(Born and Wolf 1989, p. 465). The first few NONZERO radial polynomials are

$$\begin{aligned}
R_0^0(\rho) &= 1 \\
R_1^1(\rho) &= \rho \\
R_2^0(\rho) &= 2\rho^2 - 1 \\
R_2^2(\rho) &= \rho^2 \\
R_3^1(\rho) &= 3\rho^3 - 2\rho \\
R_3^3(\rho) &= \rho^3 \\
R_4^0(\rho) &= 6\rho^4 - 6\rho^2 + 1 \\
R_4^2(\rho) &= 4\rho^4 - 3\rho^2 \\
R_4^4(\rho) &= \rho^4
\end{aligned}$$

(Born and Wolf 1989, p. 465).

The Zernike polynomial is a special case of the JACOBI POLYNOMIAL with

$$P_{n'}^{(\alpha,\beta)}(x) = (-1)^{n'} \frac{R_n^m(\rho)}{\rho^\alpha} \tag{8}$$

and

$$x = 1 - 2\rho^2 \tag{9}$$

$$\beta = 0 \tag{10}$$

$$\alpha = m \tag{11}$$

$$n' = \tfrac{1}{2}(n-m). \tag{12}$$

The Zernike polynomials also satisfy the RECURRENCE RELATIONS

$$\rho R_n^m(\rho) = \frac{1}{2(n+1)}[(n+m+2) R_{n+1}^{m+1}(\rho) + (n-m) R_{n-1}^{m+1}(\rho)] \tag{13}$$

$$R_{n+2}^m(\rho) = \frac{n+2}{(n+2)^2 - m^2} \left\{ \left[4(n+1)\rho^2 - \frac{(n+m)^2}{n} - \frac{(n-m+2)^2}{n+2} \right] R_n^m(\rho) - \frac{n^2 - m^2}{n} R_{n-2}^m(\rho) \right. \tag{14}$$

$$R_n^m(\rho) + R_n^{m+2}(\rho) = \frac{1}{n+1} \frac{d[R_{n+1}^{m+1}(\rho) - R_{n-1}^{m+1}(\rho)]}{d\rho} \tag{15}$$

(Prata and Rusch 1989). The coefficients A_n^m and B_n^m in the expansion of an arbitrary radial function $F(\rho,\phi)$ in terms of Zernike polynomials

$$F(\rho,\phi) = \sum_{m=0}^{\infty} \sum_{n=m}^{\infty} [A_n^m \, {}^oU_n^m(\rho,\phi) + B_n^m \, {}^eU_n^m(\rho,\phi)] \tag{16}$$

are given by

$$\begin{matrix} A_n^m \\ B_n^m \end{matrix} = \frac{(n+1)}{\epsilon_{mn}{}^2\pi} \int_0^1 \int_0^{2\pi} F(\rho,\phi) \begin{matrix} {}^oU_n^m(\rho,\phi) \\ {}^eU_n^m(\rho,\phi) \end{matrix} \rho\, d\phi\, d\rho, \tag{17}$$

where

$$\epsilon_{mn} \equiv \begin{cases} \epsilon \equiv \frac{1}{\sqrt{2}} & \text{for } m=0,\ n \neq 0 \\ 1 & \text{otherwise} \end{cases} \tag{18}$$

Let a "primary" aberration be given by

$$\Phi = a'_{lmn} Y_1^{2l+m^*}(\theta,\phi)\rho^n \cos^m\theta \tag{19}$$

with $2l+m+n=4$ and where Y^* is the COMPLEX CONJUGATE of Y, and define

$$A'_{lmn} = a'_{lmn} Y_1^{2l+m^*}(\theta,\phi), \tag{20}$$

giving

$$\Phi = \frac{1}{\epsilon_{nm}{}^2} A_{lmn} R_n^m(\rho)\cos(m\theta). \tag{21}$$

Then the types of primary aberrations are given in the following table (Born and Wolf 1989, p. 470).

Aberration	l	m	n	A	A'
spherical aberration	0	4	0	$A'_{040}\rho^4$	$\epsilon A_{040} R_4^0(\rho)$
coma	0	3	1	$A'_{031}\rho^3\cos\theta$	$A_{031} R_3^1(\rho)\cos\theta$
astigmatism	0	2	2	$A'_{022}\rho^2\cos^2\theta$	$A_{022} R_2^2(\rho)\cos(2\theta)$
field curvature	1	2	0	$A'_{120}\rho^2$	$\epsilon A_{120} R_2^0(\rho)$
distortion	1	1	1	$A'_{111}\rho\cos\theta$	$A_{111} R_1^1(\rho)\cos\theta$

Zero

The INTEGER denoted 0 which, when used as a counting number, means that no objects are present. It is the only INTEGER (and, in fact, the only REAL NUMBER) which is neither NEGATIVE nor POSITIVE. A number which is not zero is said to be NONZERO.

Because the number of PERMUTATIONS of 0 elements is 1, 0! (zero FACTORIAL) is often defined as 1. This definition is useful in expressing many mathematical identities in simple form. A number *other than 0* taken to the POWER 0 is defined to be 1. 0^0 is undefined, but defining $0^0 = 1$ allows concise statement of the beautiful analytical formula for the integral of the generalized SINC FUNCTION

$$\int_0^\infty \frac{\sin^a x}{x^b}\,dx = \frac{\pi^{1-c}(-1)^{\lfloor (a-b)/2 \rfloor}}{2^{a-c}(b-1)!} \times \sum_{k=0}^{\lfloor a/2 \rfloor - c} (-1)^k \binom{a}{k} (a-2k)^{b-1}[\ln(a-2k)]^c$$

given by Kogan, where $a \geq b > c$, $c \equiv a - b \pmod 2$, and $\lfloor x \rfloor$ is the FLOOR FUNCTION.

The following table gives the first few numbers n such that n^k contains no zeros, for small k. The largest known n for which 2^n contain no zeros is 86 (Madachy 1979), with no other $n \leq 4.6 \times 10^7$ (M. Cook), improving the 3.0739×10^7 limit obtained by Beeler *et al.* (1972). The values $a(n)$ such that the positions of the right-most zero in $2^{a(n)}$ increases are 10, 20, 30, 40, 46, 68, 93, 95, 129, 176, 229, 700, 1757, 1958, 7931, 57356, 269518, ... (Sloane's A031140). The positions in which the right-most zeros occur are 2, 5, 8, 11, 12, 13, 14, 23, 36, 38, 54, 57, 59, 93, 115, 119, 120, 121, 136, 138, 164, ... (Sloane's A031141). The right-most zero of $2^{781,717,865}$ occurs at the 217th decimal place, the farthest over for powers up to 2.5×10^9.

k	Sloane	n such that n^k contains no 0s
2	007377	1, 2, 3, 4, 5, 6, 7, 8, 9, 13, 14, 15, 16, ...
3	030700	1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 12, 13, 14, ...
4	030701	1, 2, 3, 4, 7, 8, 9, 12, 14, 16, 17, 18, ...
5	008839	1, 2, 3, 4, 5, 6, 7, 9, 10, 11, 17, 18, 30, ...
6	030702	1, 2, 3, 4, 5, 6, 7, 8, 12, 17, 24, 29, 44, ...
7	030703	1, 2, 3, 6, 7, 10, 11, 19, 35, ...
8	030704	1, 2, 3, 5, 6, 8, 9, 11, 12, 13, 17, 24, 27, ...
9	030705	1, 2, 3, 4, 6, 7, 12, 13, 14, 17, 34, ...
11	030706	1, 2, 3, 4, 6, 7, 8, 9, 12, 13, 14, 15, 16, ...

While it has not been proven that the numbers listed above are the only ones without zeros for a given base, the probability that any additional ones exist is vanishingly small. Under this assumption, the sequence of largest n such that k^n contains no zeros for $k = 2$, 3, ... is then given by 86, 68, 43, 58, 44, 35, 27, 34, 0, 41, ... (Sloane's A020665).

Zero Divisor

A NONZERO element x of a RING for which $x \cdot y = 0$, where y is some other NONZERO element and the vector multiplication $x \cdot y$ is assumed to be BILINEAR. A RING with no zero divisors is known as an INTEGRAL DOMAIN. Let A denote an $\mathbb{R}$-algebra, so that A is a VECTOR SPACE over R and

$$A \times A \to A$$

$$(x, y) \mapsto x \cdot y.$$

Now define

$$Z \equiv \{x \in A : x \cdot y = 0 \text{ for some NONZERO } y \in A\},$$

where $0 \in Z$. A is said to be m-ASSOCIATIVE if there exists an m-dimensional SUBSPACE S of A such that $(y \cdot x) \cdot z = y \cdot (x \cdot z)$ for all $y, z \in A$ and $x \in S$. A is said to be TAME if Z is a finite union of SUBSPACES of A.

Zillion

A generic word for a very LARGE NUMBER. The term has no well-defined mathematical meaning. Conway and Guy (1996) define the nth zillion as 10^{3n+3} in the American system (million $= 10^6$, billion $= 10^9$, trillion $= 10^{12}$, ...) and 10^{6n} in the British system (million $= 10^6$, billion $= 10^{12}$, trillion $= 10^{18}$, ...). Conway and Guy (1996) also define the words n-PLEX and n-MINEX for 10^n and 10^{-n}, respectively.

see also LARGE NUMBER

Zipf's Law

In the English language, the probability of encountering the rth most common word is given roughly by $P(r) = 0.1/r$ for r up to 1000 or so. The law breaks down for less frequent words, since the HARMONIC SERIES diverges. Pierce's (1980, p. 87) statement that $\sum P(r) > 1$ for $r = 8727$ is incorrect. Goetz states the law as follows: The frequency of a word is inversely proportional to its RANK r such that

$$P(r) \approx \frac{1}{r\ln(1.78R)},$$

where R is the number of different words.

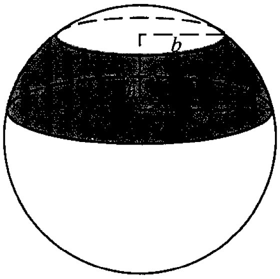
Zonal Harmonic

A SPHERICAL HARMONIC which is a product of factors linear in x^2, y^2, and z^2, with the product multiplied by z when n is ODD.

see also TESSERAL HARMONIC

Zone



The SURFACE AREA of a SPHERICAL SEGMENT. Call the RADIUS of the SPHERE R, the upper and lower RADII b and a, respectively, and the height of the SPHERICAL SEGMENT h. The zone is a SURFACE OF REVOLUTION about the z-AXIS, so the SURFACE AREA is given by

$$S = 2\pi \int x\sqrt{1+x'^2}\,dz. \tag{1}$$

In the xz-plane, the equation of the zone is simply that of a CIRCLE,

$$x = \sqrt{R^2 - z^2}, \tag{2}$$

so

$$x' = -z(R^2 - z^2)^{-1/2} \tag{3}$$

$$x'^2 = \frac{z^2}{R^2 - z^2}, \tag{4}$$

and

$$\begin{aligned} S &= 2\pi \int_{\sqrt{R^2-a^2}}^{\sqrt{R^2-b^2}} \sqrt{R^2 - z^2}\sqrt{1 + \frac{z^2}{R^2 - z^2}}\,dz \\ &= 2\pi R \int_{\sqrt{R^2-a^2}}^{\sqrt{R^2-b^2}} dz = 2\pi R(\sqrt{R^2 - b^2} - \sqrt{R^2 - a^2}\,) \\ &= 2\pi Rh. \end{aligned} \tag{5}$$

This result is somewhat surprising since it depends only on the *height* of the zone, not its vertical position with respect to the SPHERE.

PREFACE

Philosophy is sometimes described as the study of what people take for granted. It examines the reasons why people make assumptions about things in their lives by understanding the relationships between the basic ‘‘truths’’ that are used to come up with these assumptions. This analysis takes a very precise logical path that is scientific in nature. For example, the following statement can be broken down into a set of simple truths and the relationships between them plotted out and understood to allow philosophers to carry on the natural thought process (such as what is a body that has three ‘‘extensions’’ with a ‘‘thinking substance’’).

> Thus, extension in length, breadth and depth, constitutes the nature of corporeal substance; and thought constitutes the nature of thinking substance. For all else that may be attributed to body presupposes extension, and is but a mode of this extended thing; as everything that we find in mind is but so many diverse forms of thinking.
>
> Descartes

Surprisingly enough, the rules that were developed for understanding philosophic statements like the one above were applied in the 1930s and 1940s to help define how electrical circuits could be designed that would be used in the first electronic computers. One of the elements of the success of this effort was to reduce the electronic logic ‘‘truths’’ into two simple electrical states.

These two electrical states are often represented as two numbers that can be manipulated using ‘‘binary arithmetic.’’ Binary arithmetic was formally described by the English mathematician George Boole in the middle of the 19th century and is often referred to as ‘‘Boolean arithmetic’’ or ‘‘Boolean algebra’’ as a way to perform mathematical operations on numbers that only have two values (‘‘0’’ or ‘‘1’’). These two values are manipulated within electronic computers and other devices built from ‘‘digital electronics.’’

Over the past 60-plus years, digital logic circuits, processing binary signals have been miniaturized, sped up and integrated together to create the fantastic electronic gadgets that we take for granted. Despite their

Copyright © 2005 by The McGraw-Hill Companies, Inc. Click here for terms of use.

complexity, they operate using the basic rules and circuits that are explained in this book. After working through this book, not only will you understand how these products are designed but you will also have some experience in designing and working through the problems of implementing them on your own.

This book was written for people that would like to learn about digital electronics without taking a formal course. After working through this book, along with a reasonably good understanding of the subject as well as some of the background material needed to create electronic circuits, it can also serve as a supplemental text in a classroom, tutored or home-schooling environment. The book should also be useful for career changers who need to refresh their knowledge in electronics and would like to better understand what are the different facets of current digital electronic products.

This introductory work contains an abundance of practice quiz, test and exam questions. They are all multiple-choice and are similar to the sorts of questions used in standardized texts. There is a short quiz at the end of every chapter. The quizzes are ‘‘open-book.’’ You may (and should) refer to the chapter texts when taking them. When you think you’re ready, take the quiz, write down the answers and then give your list of answers to a friend. Have the friend tell you the score, but not which questions you got wrong. The answers are listed in the back of the book. Stick with a chapter until you get most of the answers correct.

This book is divided into two parts. At the end of each part is a multiple-choice test. Take these tests when you’ve completed with the respective sections and have taken all the chapter quizzes. The section tests are ‘‘closed-book’’, but the questions are not as difficult as those in the quizzes. A satisfactory score is three-quarters of the answers correct. Again, answers are in the back of the book.

There is a final exam at the end of this course. It contains questions drawn uniformly from all the chapters in the book. Take it when you have finished both sections, both section tests and all of the chapter quizzes. A satisfactory score is at least 75% correct answers.

With the section tests and the final exam, as with the quizzes, have a friend tell you your score without letting you know which questions you missed. That way, you will not subconsciously memorize the answers. You can check to see where your knowledge is strong and where it is not.

I recommend that you complete one chapter a week. An hour or two daily ought to be enough time for this. As part of this work, you should notice that I have given a number of suggestions on how you could implement the described circuits to see exactly how they work. When you’ve worked through this material, you can use this book as a permanent reference.

Now, work hard, but be sure to have fun and look to see where you can use the information provided here to help you to understand how the complex electronic devices of modern society are implemented using digital logic devices that are just capable of following simple rules of logic.

myke

ACKNOWLEDGMENT

I would like to thank my wife, Patience, for her love and support and willingness to become the first person to have worked through the material in this book. Without her support, suggestions, love, and willingness to understand what ‘‘fanout’’ means, this book and its material would never have been possible.

CHAPTER 1

The Underpinnings of Digital Electronics

If you were asked to define what a bit is, chances are you would probably do a pretty good job, saying something like:

> A bit is something that can only have two values: on or off.

Instead of "on or off", you might have used terms for two values like "one or zero", "high or low voltage", "up or down", "empty or full" or (if you fancy yourself as being erudite) "dominant or recessive". All of these terms are correct and imply that the two values are at opposite extremes and are easily differentiated.

When you think of "bits", you are probably thinking of something in a wire or an electronic device contained within a computer, but when the concept of binary (two state) logic was first invented, the values that were

Copyright © 2005 by The McGraw-Hill Companies, Inc. Click here for terms of use.

applied were tests to see if a statement was ‘‘true’’ or ‘‘false’’. Examples of true and false statements are:

- The sun always rises in the East. (true)
- Dogs live at the bottom of the ocean like fish. (false)

Looking at these simple statements determining if they are true or false seems to reduce the information within to an extreme degree. The truthfulness of a statement can be combined with another statement to help determine if a more complex postulate is true. If you consider the following ‘‘true’’ statements:

- A dog has fur over its body.
- A dog has four legs.
- Animals have four legs and fur.
- Humans have two legs.
- A snake has scales on its body.
- A reptile’s body has scales or smooth skin.

and combining them together, you can make some surprisingly complex ‘‘assertions’’ from these data using three basic operations. These three basic operations consist of ‘‘AND’’ which is true if all the statements combined together by the AND are true, ‘‘OR’’ which is true if any of the combined statements are true and ‘‘NOT’’ which is true if a single statement is false. To differentiate these three operations from their prose synonyms, I will capitalize them (as well as other basic logic operations) throughout the book. These operations are often called ‘‘logic operations’’ because they were first used to understand the logic of complex philosophical statements.

From the seven statements above and using these three basic operations, you can make the following true assertions:

- Humans are not dogs.
- A dog is an animal.
- A snake is a reptile.

The first statement is true because we know that a human has two legs (violating a condition that is required for the definition of a dog to be true). This is an example of the ‘‘negation’’ or ‘‘NOT’’ operation; the assertion is true if the single input statement is false:

> The room is dark because the lights are not on.

The NOT function is often called an ‘‘Inverter’’ because it changes the value of the input from high to low and vice versa.

The second assertion, “A dog is an animal”, is true because both of the two statements concerning animals are true when applied to dogs (which have four legs and fur). This is an example of the “AND” operation; the assertion is true if and only if the input statements are true. The AND operation has two or more input statements. In trying to differentiate bicycles and motorcycles from cars, you might make the assertion which uses the AND operation:

> A car has four wheels and a motor.

The last assertion, “A snake is a reptile”, is true because one of the two statements giving the necessary characteristics for a reptile is true. This is an example of an “inclusive or” (usually referred to as just “OR”) operation; the assertion is true if any of the input statements are true. Like the “and” operation, OR can have two or more input statements. If you’re a parent, you will be familiar with the assertion:

> During the course of a day, a baby eats, sleeps, cries or poops.

I use this example to illustrate an important point about the “OR” operation that is often lost when it is used in colloquial speech: if more than one input statement is true, the entire assertion is still true. As incredible as it sounds to someone who has not had children yet, a baby is very capable of performing all four actions listed above simultaneously (and seemingly constantly).

I’m making this point because when we speak, we usually use the “exclusive or” instead of “inclusive or” to indicate that only one of two actions can be true. An example statement in which an “exclusive or” is used in everyday speech could be:

> Tom is at a restaurant or the movies.

This is an example of “exclusive OR” because Tom can only be at one of the two places at any given time. I will discuss the “exclusive or” operation in more detail later in this chapter, but for now try to remember that an assertion using the “OR” operation will be true if one or more of the input statements are true.

So far I have been working with “bits” of “binary” information contained in “statements” and “assertions”. You are probably wondering why a term like “bit electronics” or “binary electronics” is used instead of “digital electronics”. “Digital” comes from the Latin word for “fingers” and indicates that there are many discrete signals that are at one of two values. Naming the circuitry “bit electronics” or “binary electronics” would imply that it can only work with one piece of information; digital electronic circuits can process many bits of information simultaneously, either as separate pieces of information or collections of large amounts of data.

In the first few pages of this book, I have introduced you to the concept of the ‘‘bit’’, the ‘‘digit’’, the ‘‘NOT’’, ‘‘AND’’ and ‘‘OR’’ operations along with the ‘‘exclusive OR’’. Different combinations of these concepts are the basis for the majority of the material presented through the remainder of this book and any course in digital electronics. I suggest that you read over this chapter and make sure you are completely comfortable with the terms and how they work before going on.

Boolean Arithmetic, Truth Tables and Gates

In the introduction to this chapter, I demonstrated the operation of the three operations ‘‘AND’’, ‘‘OR’’ and ‘‘NOT’’, which can be used to test input values (which are in the form of two state ‘‘bits’’) and produce assertions based on the state of the input bits. The verbose method I used could be used with digital electronics, but you will find that it is cumbersome and not intuitively obvious when you are working with electronic circuits. Fortunately, a number of different tools have been developed to simplify working with logic operations.

The first tool that simplifies how logic operations are expressed is known as ‘‘Boolean arithmetic’’ (or sometimes as ‘‘Boolean logic’’), a branch of mathematics where a mathematical expression is used to express how bit inputs can be transformed into an output using the three operations presented in the introduction. Boolean arithmetic was first described by the English mathematician Charles Lutwidge Dodgson, whom you may be familiar with by his nom de plume Lewis Carroll, and expanded upon by George Boole, in the mid 19th century, as a way of understanding, proving or disproving complex philosophical statements. Boole demonstrated that a statement, involving bits of data and the AND, OR or NOT operations could be written in the form:

```
Result = Data1 operation Data2  {operation Data3...}
```

The braces (‘‘{‘‘ and ’’}’’) are often used to indicate that what’s inside them is optional and the three periods (‘‘. . .’’) indicate that the previous text can be repeated. Using these conventions you can see that a Boolean arithmetic statement is not limited to just one operation with two input bits – they can actually be very lengthy and complex with many bit inputs and multiple operations.

To demonstrate how a Boolean arithmetic statement could be articulated, I can write the proof that a dog is an animal in the form:

`Result = (Does Dog have 4 Legs)   AND   (Does Dog have Fur)`

If both statements within the parentheses are true, then the “Result” will be true.

This method of writing out assertions and the logic behind them is quite a bit simpler and much easier to understand, but we can do better. Instead of writing out the true or false statement as a condition, it can be expressed in terms of a simple “variable” (like “X”). So, if we assign “A” as the result of testing if dogs have four legs and “B” as the result of testing if dogs have fur, we can write out the Boolean arithmetic equation above as:

`Result = A AND B`

To further simplify how a logic operation is written out, the basic characters “.”, “+” and “!” can be used instead of AND, OR and NOT, respectively. AND behaves like a binary multiplication, so along with the “·” character, you may see an “x” or “*”. The OR operation may be represented as “|”. The ampersand (“&”) for AND and “|” for OR are often used because they are the same symbols as are used in most computer programming languages. When I write out Boolean arithmetic equations throughout the book, I will be using the “.”, “+” and “!” characters for the three basic logic operations instead of the full words.

An important advantage of converting a statement into a simple equation is that it more clearly shows how the logic operation works. If the variables “A” and “B” were just given the values of “true” or “false”, the “Result” of the equation above could be written out in the form shown in Table 1-1. This is known as a “truth table” and it is a very effective way of expressing how a Boolean operator works. The truth table is not limited to just three inputs,

Table 1-1 “AND” operation truth table using Gray code inputs.

Input “A”	Input “B”	“AND” Output
False	False	False
False	True	False
True	True	True
True	False	False

and a function with more than one Boolean operator can be modeled in this way. Functions with more than one output can be expressed using the truth table, but I don't recommend doing this because relationships between inputs and outputs (which I will discuss in greater detail later in the book) can be obscured.

One other thing to notice about the truth table is that I have expressed the inputs as a "Gray code", rather than incrementing inputs. Gray codes are a technique for sequencing multiple bits in such a way that only one bit changes from one state to the next. Incrementing inputs behave as if the inputs were bits of a larger binary number and the value of this number is increased by one when moving from one state to the next. The truth table above, for the "AND" gate could be written out using incrementing inputs as Table 1-2.

In many cases, truth tables are introduced with incrementing inputs, but I would like to discourage this. Incrementing inputs can obscure relationships between inputs that become obvious when you use Gray codes. This advantage will become more obvious as you work through more complex logic operations and are looking for ways to simplify the expression.

The OR operation's truth table is given in Table 1-3, while the NOT operation's truth table is shown in Table 1-4.

The OR operation would be written in Boolean arithmetic, using the "+" character to represent the OR operation as:

$$\texttt{Output} = \texttt{A} + \texttt{B}$$

and the NOT operation (using the "!" character) is written out in Boolean arithmetic as:

$$\texttt{Output} = \texttt{!A}$$

Table 1-2 "AND" operation truth table using incrementing inputs.

Input "A"	Input "B"	"AND" Output
False	False	False
False	True	False
True	False	False
True	True	True

Table 1-3 "OR" operation truth table using Gray code inputs.

Input "A"	Input "B"	"OR" Output
False	False	False
False	True	True
True	True	True
True	False	True

Table 1-4 "NOT" operation truth table using Gray code inputs.

Input	"NOT" Output
False	True
True	False

Sometimes, when a signal is NOTted, its symbol is given either a minus sign ("–") or an underscore ("_") as its first character to indicate that it has been inverted by a NOT operation.

The final way of expressing the three basic logic operations is graphically with the inputs flowing through lines into a symbol representing each operation and the output flowing out of the line. Figures 1-1 through 1-3 show the graphical representations of the AND, OR and NOT gates, respectively.

Fig. 1-1. "AND" gate.

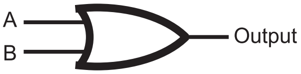

Fig. 1-2. "OR" gate.

Fig. 1-3. "NOT" gate.

The graphical representation of the logic operations is a very effective way of describing and documenting complex functions and is the most popular way of representing logic operations in digital electronic circuits. When graphics are used to represent the logic operations, they are most often referred to as "gates", because the TRUE is held back until its requirements are met, at which point it is allowed out by opening the gate. "Gate" is the term I will use most often when describing Boolean arithmetic operations in this book.

If you were to replace the lines leading to each gate with a wire and the symbol with an electronic circuit, you can transfer a Boolean arithmetic design to a digital electronic circuit directly.

The Six Elementary Logic Operations

When you look at a catalog of digital electronics chips, you are going to discover that they are built from ANDs, ORs and NOTs as well as three other elementary gates. Two of these gates are critically important to understand because they are actually the basis of digital logic while the third is required for adding numbers together.

TTL logic is based on the "NAND" gate which can be considered a "NOTted AND" – the output of an AND gate is passed through a NOT gate as shown in Fig. 1-4. Instead of drawing the NAND gate as an AND gate and NOT gate connected together as in Fig. 1-4, they are contracted into the one symbol shown in Fig. 1-5. It's truth table is in Table 1-5.

When writing out the NAND function in Boolean arithmetic, it is normally in the form:

$$\texttt{Output} = !(\texttt{A} \cdot \texttt{B})$$

which is a literal translation of the operation – the inputs are ANDed together and the result is NOTted before it is passed to the Output.

Fig. 1-4. "NAND" gate made from "AND" and "OR" gates.

Fig. 1-5. "NAND" gate.

Table 1-5 “NAND” operation truth table.

Input “A”	Input “B”	“NAND” Output
False	False	True
False	True	True
True	True	False
True	False	True

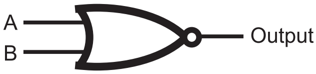

Fig. 1-6 “NOR” gate.

You will see the small circuit on various parts in different electronic devices, both on inputs and outputs. The small circle on the NAND gate is the conventional shorthand symbol to indicate that the input or output of a gate is NOTted.

In case you didn’t note the point above, the NAND gate is the basis for TTL logic, as I will explain later in the book. Being very comfortable with NAND gates is very important to being able to design and use TTL electronics. This is a point that I find is not stressed enough in most electronics courses and by having a strong knowledge of how NAND gates work as well as how they are implemented you will better understand what is happening within your digital electronics circuits.

If you are going to be working with CMOS logic, in the same way you should be comfortable with the NAND gate for TTL, you should be familiar with the “NOR” gate (Fig. 1-6). The NOR gate can be considered to be a contraction of the OR and NOT gates (as evidenced by the circle on the output of the OR gate) and operates in the opposite manner as the OR gate, as shown in Table 1-6. When using NOR operations in Boolean arithmetic, a similar format to the NAND gate is used:

$$\texttt{Output} = !\,(\texttt{A} + \texttt{B})$$

The last elementary logic gate that you will have to work with is the “Exclusive OR” (Fig. 1-7) with Table 1-7 being its truth table. The

Table 1-6 "NOR" operation truth table.

Input "A"	**Input "B"**	**"NAND" Output**
False	False	True
False	True	False
True	True	False
True	False	False

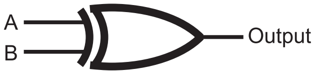

Fig. 1-7. "XOR" gate.

Table 1-7 "Exclusive OR" operation truth table.

Input "A"	**Input "B"**	**"Exclusive OR" Output**
False	False	False
False	True	True
True	True	False
True	False	True

Exclusive OR (also referred to as "Ex-OR" or "XOR") only returns a True output if only one of its inputs is true. If both inputs are the same, then the Exclusive OR outputs False. The Boolean arithmetic symbol for Exclusive OR is often a caret ("^") as is used in computer programming languages or a circle with an "x" character in it $\otimes$. Writing a Boolean statement with the Exclusive OR would be in the format:

`Output = A ^ B`

Table 1-8 summarizes the six elementary gates along with their Boolean arithmetic symbols and formats, graphical symbols and truth tables.

Table 1-8 Summary of the six elementary logic operations.

Gate	Boolean arithmetic symbols	Boolean arithmetic equation	Graphic symbol	Truth table
AND	·, &, *, x	Out = A · B		A B | Out −− −− + −− F F | F F T | F T T | T T F | F
OR	+, |	Out = A + B		A B | Out −− −− + −− F F | F F T | T T T | T T F | T
NOT	!, _, -	Out = ! A		A | Out −− + −− F | T T | F
NAND	! ·	Out = ! (A · B)		A B | Out −− −− + −− F F | T F T | T T T | F T F | T
NOR	! +	Out = ! (A + B)		A B | Out −− −− + −− F F | T F T | F T T | F T F | F
Exclusive OR	ˆ, ⊙	Out = A ˆ B		A B | Out −− −− + −− F F | F F T | T T T | F T F | T

Combinatorial Logic Circuits: Combining Logic Gates

As I hinted at in the previous section, multiple gate functions can be combined to form more complex or different Boolean logic functions. Wiring together multiple gates are used to build a complex logic function that only outputs a specific value when a specific combination of True and False inputs are passed to it is known as "combinatorial logic". The output of a combinatorial logic circuit is dependent on its input; if the input changes then the output will change as well.

When I wrote the preceding paragraph, I originally noted that combinatorial logic circuits produce a "True" output for a given set of inputs. This is incorrect, as there will be some cases where you will require a False output in your application. I made the definition a bit more ambiguous so that you do not feel like the output has to be a single, specific value when the input consists of the required inputs. It is also important to note that in a combinatorial logic circuit, data flows in one direction and outputs in logic gates cannot be used as inputs to gates which output back to themselves. These two points may seem subtle now, but they are actually critically important to the definition of combinatorial logic circuits and using them in applications.

An example of a combinatorial circuit is shown in Fig. 1-8. In this circuit, I have combined three AND gates, a NOR gate, a NOT gate and an XOR gate to produce the following logic function:

$$\texttt{Output} = ((\texttt{A} \cdot \texttt{B}) \cdot !(!(\texttt{A} + \texttt{C}))) \mathbin{\hat{}} (!(\texttt{A} + \texttt{C}) \cdot \texttt{B})$$

This combinatorial circuit follows the convention that inputs to a gate (or a chip or other electronic component) are passed into the left and outputs

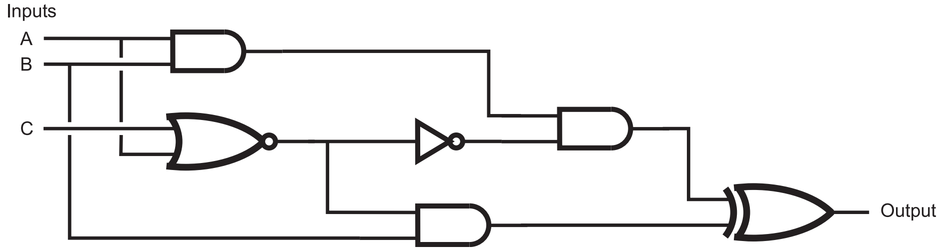

Fig. 1-8 Combinatorial circuit built from multiple logic gates.

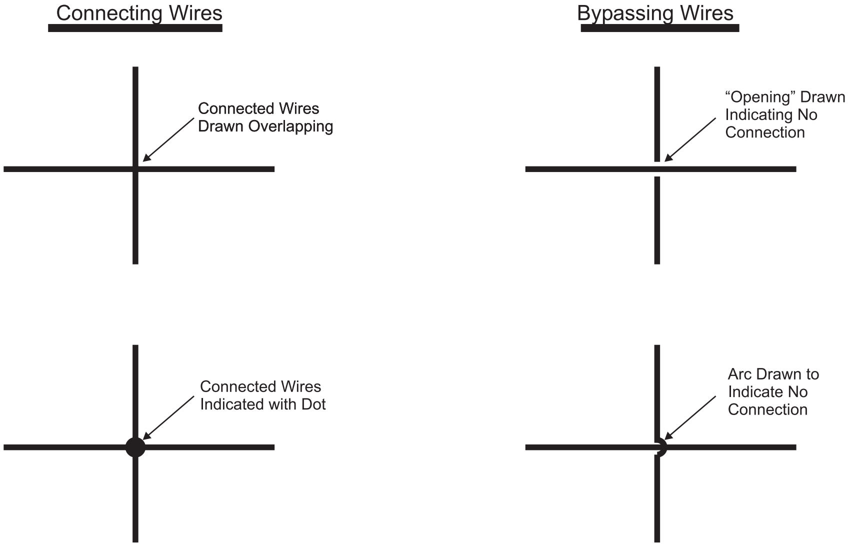
exit from the right. This will help you "read" the circuit from left to right, something that should be familiar to you.

While seeing a series of logic gates, like the one in Fig. 1-8, seems to be overwhelming, you already have the tools to be able to work through it and understand how it works. In the previous section, I noted that gates could be connected by passing the output of one into an input of another; a combinatorial circuit (like Fig. 1-8) is simply an extension of this concept and, being an extension, you can use the same tools you used to understand single gates to understand the multiple gate operation.

I should point out that the two broken lines on the left side of Fig. 1-8 (leading down from "A" and "B") indicate that these lines are not connected to the lines that they intersect with. You will find that it can be very difficult to design logic circuits without connected and separate lines from becoming confused. In Fig. 1-9, I have shown a couple of the conventional ways of drawing intersecting lines, depending on whether or not they connect or bypass each other. Probably the most intuitively obvious way of drawing connecting and bypassing lines is to use the dot and arc, respectively. I tend not to because they add extra time to the logic (and circuit) diagram drawing process. As you see more circuit diagrams, you will see the different conventions used and you should be comfortable with recognizing what each means.



Connecting Wires
Bypassing Wires
Connected Wires Drawn Overlapping
"Opening" Drawn Indicating No Connection
Connected Wires Indicated with Dot
Arc Drawn to Indicate No Connection

Fig. 1-9. Different representations for wires that connect or bypass.

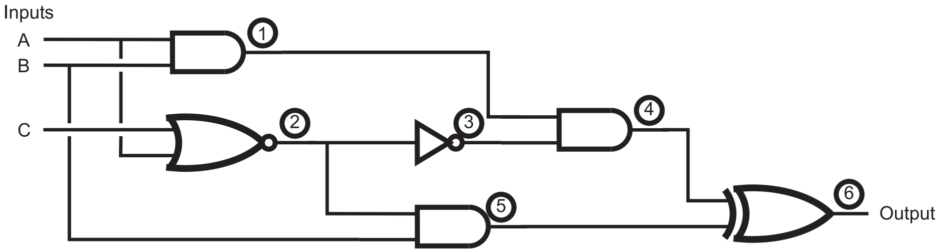


Fig. 1-10. Combinatorial circuit with logic gate outputs marked.

When I am faced with a complex combinatorial circuit, the first thing I do is to mark the outputs of each of the gates (Fig. 1-10) and then list them according to their immediate inputs:

$$\texttt{Output 1} = \texttt{A} \cdot \texttt{B}$$

$$\texttt{Output 2} = !(\texttt{A} + \texttt{C})$$

$$\texttt{Output 3} = !\texttt{2}$$

$$\texttt{Output 4} = \texttt{1} \cdot \texttt{3}$$

$$\texttt{Output 5} = \texttt{B} \cdot \texttt{2}$$

$$\texttt{Output 6} = \texttt{4}\,\hat{}\,\texttt{5}$$

After listing them, I then work through a truth table, passing the outputs of each gate along until I have the final outputs of the complete function (Table 1-9). In keeping with my comments of the previous section, I have used a three bit Gray code for the inputs to this circuit.

Before going on, there are two points that I would like you to keep in the back of your mind. First, this is actually quite an efficient methodology for decoding combinatorial circuits that you are given the design for. Designing a logic gate circuit that responds in a specific manner is actually quite a different process and I will be devoting the rest of this chapter as well as the next to explaining the design and optimization of combinatorial circuits. Once you have finished with Chapter 2, you might want to revisit the example circuit in Fig. 1-8 and see how effectively you can reduce its complexity and the number of logic gates needed to implement it.

The second point that you should be aware of is the example circuit that I used in this section is actually quite unwieldy and does not conform to the typical methods used to design most practical combinatorial digital electronic circuits. In the next section, I will present you with the conventional methods for specifying and documenting combinatorial circuits.

Table 1-9 Decoding the response of the combinatorial circuit in Fig. 1-8.

Inputs			1 = A · B	2 = !(A + C)	3 = !2	4 = 1 · 3	5 = B · 2	6 = 4 ˆ 5
A	B	C						
F	F	F	False	True	False	False	False	False
F	F	T	False	False	True	False	False	False
F	T	T	False	False	True	False	False	False
F	T	F	False	True	False	False	True	True
T	T	F	True	False	True	True	False	True
T	T	T	True	False	True	True	False	True
T	F	T	False	False	True	False	False	False
T	F	F	False	False	True	False	False	False

Sum of Products and Product of Sums

Presenting combinatorial circuits as a collection of gates wired together almost randomly, like the circuit shown in Fig. 1-8, is sub-optimal from a variety of perspectives. The first is, the function provided by the combinatorial circuit is not obvious. Secondly, using a variety of different gates can make your parts planning process difficult, with only one gate out of many available in a chip being used. Lastly, the arrangement of gates will be difficult for automated tools to combine on a printed circuit board (“PCB”) or within a logic chip. What is needed is a conventional way of drawing combinatorial logic circuits.

The most widely used format is known as “sum of products”. Earlier in the chapter, I presented the concept that the AND operation was analogous to multiplication just as the OR operation is to addition. Using this background, you can assume that a “sum of products” circuit is built from AND and OR gates. Going further, you might also guess that the final output is the “OR” (because addition produces a “sum”) with the gates that

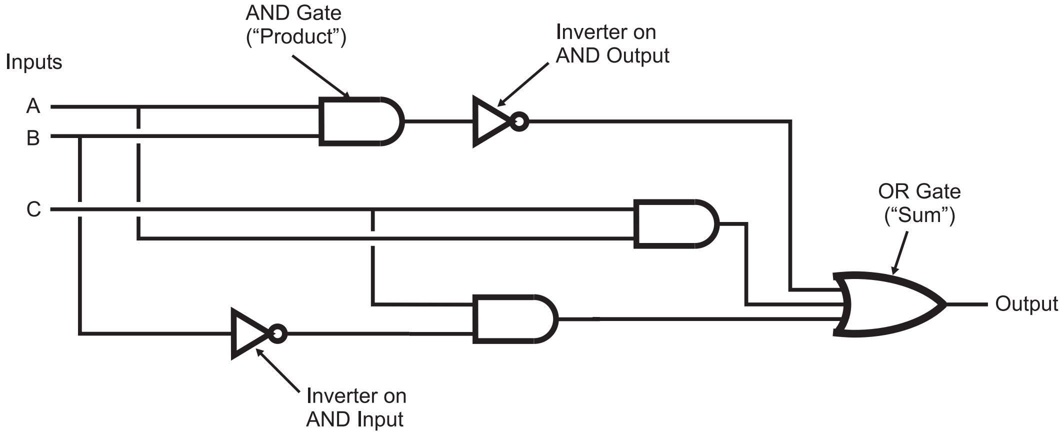

Fig. 1-11. Example "sum of products" combinatorial logic circuit.

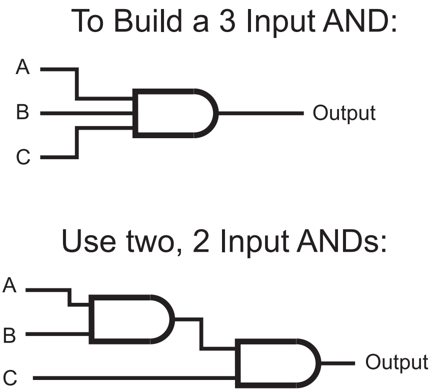
convert the inputs being "AND" gates (a "product" is the result of a multiplication operation). An example "sum of products" combinatorial logic circuit is shown in Fig. 1-11.

In this circuit, the inputs are ANDed together and the result is passed to an OR gate. In this circuit, the output will be "True" if any of the inputs to the OR gate (which are the outputs from the AND gates) are true. In some cases, to make sure that the inputs and outputs of the AND gates are in the correct state, they will be inverted using NOT gates, as I have shown in Fig. 1-11.

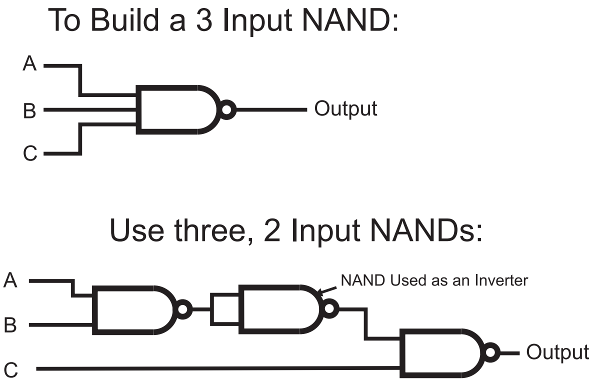
Figure 1-11 has one feature that I have not introduced to you yet and that is the three input OR gate on the right side of the diagram. So far, I have only discussed two input gates, but I should point out that three input gates can be built from multiple two input gates, as I show in Fig. 1-12, in which two, two input AND gates are combined to form a single three input AND gate. A three input OR gate could be built exactly the same way.

A three input NAND or NOR gate is a bit trickier, as Fig. 1-13 shows. For this case, the output of the NAND gate processing "A" and "B" must be inverted (which can be accomplished with a NAND gate and both inputs tied together as I show in Fig. 1-13) to make its output the same as an "AND". The NAND gate's function is to first AND its inputs together and then invert them before driving out the output signal. As I will explain in greater detail in the next chapter, an inverted output, when it is inverted, becomes a "positive" output and I use this rule to produce the three input NAND gate. A three input NOR gate would be built in exactly the same way as a three input NAND gate.



To Build a 3 Input AND:
A
B
C
Output
Use two, 2 Input ANDs:
A
B
C
Output

Fig. 1-12. 3 Input AND gate built from 2 input AND gates.



To Build a 3 Input NAND:
A
B
C
Output
Use three, 2 Input NANDs:
A
B
C
NAND Used as an Inverter
Output

Fig. 1-13. 3 Input AND gate built from 2 input AND gates.

Along with having a “sum of products” combinatorial logic circuit that outputs a True when one of the intermediate AND gates outputs True, there is the complementary “product of sums” (Fig. 1-14), which outputs False when one of its intermediate OR gates outputs False.

While product of sums combinatorial circuits can produce the same functions as sum of product combinatorial circuits, you will not see as many product of sum combinatorial circuits in various designs because they rely on what I call “negative logic”. Most people cannot easily visualize something happening because the inputs do not meet an expected case, which is exactly what happens in a product of sums combinatorial logic circuit.

To demonstrate how a sum of product combinatorial logic circuit is designed, consider the messy combinatorial logic circuit I presented

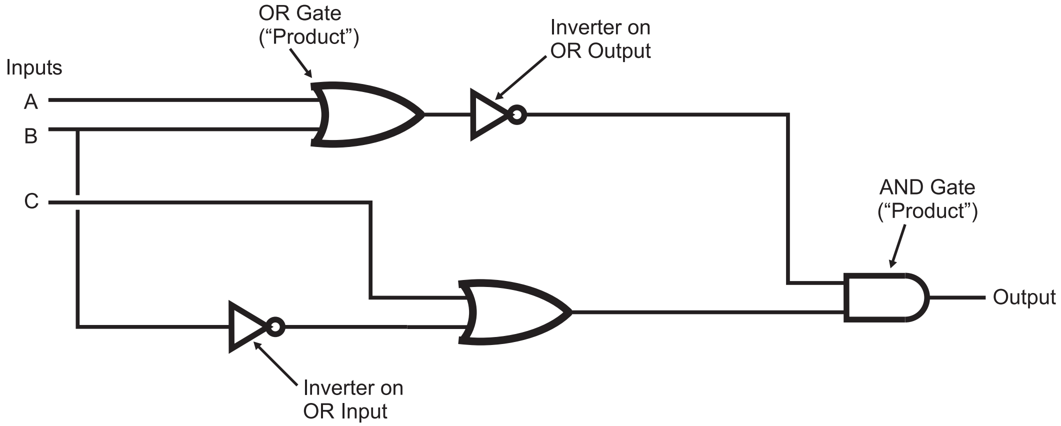


Fig. 1-14. Example "product of sums" combinatorial logic circuit.

in the previous section (see Fig. 1-8). To understand the operation of this circuit, I created a large truth table (Table 1-9) and listed the outputs of each of the intermediate gates and finally discovered that the function output True in three cases that can be directly translated into AND operations by assuming that in each case the output was true and the input conditions were all true. To make all three inputs True to the AND gates when the input is False, I invert them and came up with the three statements below:

```
A . B · !C
A · B · C
!A · B · !C
```

These three AND statements can be placed directly into a sum of products combinatorial circuit, as shown in Fig. 1-15.

Looking at Fig. 1-15, you'll probably notice that this circuit has the same total number of gates as the original circuit – and, assuming that each three input gate is made up of two, two input AND gates, it probably requires four *more* gates than the original circuit shown in Fig. 1-8. The only apparent advantage to the sum of product format for combinatorial logic circuit is that it is easier to follow through and see that the output is True for the three input conditions I listed above.

In the following chapters, I will introduce you to combinatorial logic circuit optimization as well as explain in more detail how digital electronic gates are actually built. It will probably be surprising to discover that the sum

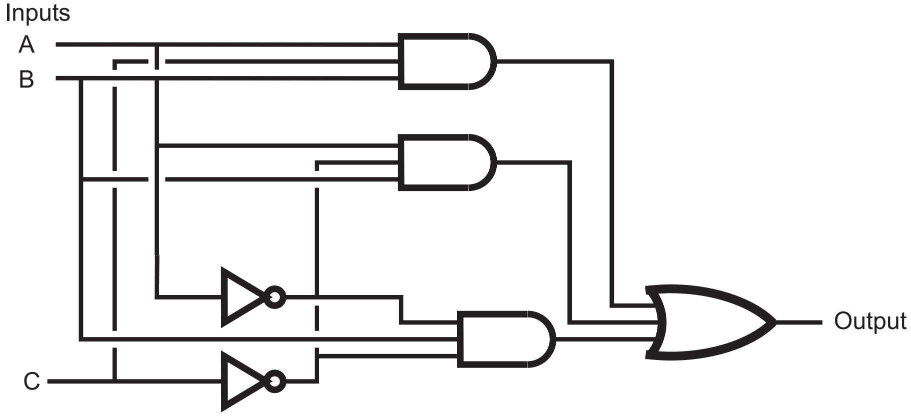

Fig. 1-15. Original combinatorial circuit built in "sum of products" format.

of product combinatorial logic circuit format leads to applications that are more efficient (in terms of total gate or transistor count along with speed and heat dissipation) than ones using less conventional design methodologies.

Waveform Diagrams

So far in this chapter, I have shown how logic functions can be presented as English text, mathematical equations (Boolean arithmetic), truth tables and graphical circuit diagrams. There are actually two more ways in which the logic data can be presented that you should be familiar with. The first method is not one that you will see a lot of except when debugging microprocessor instructions from a very low level, while the second is one that you will have to become very familiar with, especially when the digital electronic signals pass from the combinatorial logic shown here to more complex circuits that have the ability to "store" information.

The first method, the "state list" consists of a list of text columns for each state of the circuit. The state list is really a compressed form of the truth table and is best suited for displaying a fairly large amount of numerical data. Going back to the example circuit of Fig. 1-8, and Table 1-9, I could express the truth table as the series of columns below. Note that I have used the numeric values "1" for True and "0" for False because they are easier to differentiate than "T" and "F" over a number of rows.

```
ABC123456   < — Signals being displayed
000010000
001001000
011001000
010010010
110101101
111101101
101001000
100001000
```

As I said, not a lot of information is obvious from the state list. Some formatting could be done to make the inputs and outputs better differentiated, but for the most part, I don't recommend using state lists for most digital electronics applications. Where the state list is useful is in debugging state machine or microcontroller applications in which you have added hardware to the data, address and control busses to record how the device responds to specific inputs.

The state list is not ideal for this type of application, but it's better than nothing.

The other method, which is not only recommended as a circuit analysis and design tool but is also one you should be intimately familiar with is the "waveform diagram". Waveforms are electrical signals that have been plotted over time. The original waveform display tool was the oscilloscope; a drawing of a typical oscilloscope's display is shown in Fig. 1-16.

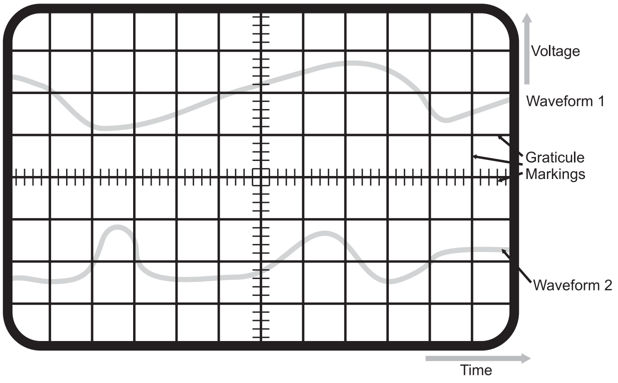

Fig. 1-16. Basics of an oscilloscope screen.

The features of the two ‘‘waveforms’’ displayed on the oscilloscope screen can be measured by placing them against the ‘‘graticule markings’’ on the display. These markings (usually just referred to as ‘‘graticules’’ and etched onto the glass screen of the oscilloscope) are indicators of a specific passage of time or change in voltage. Along with the ‘‘gross’’ graticules, most oscilloscopes have finer markings, to allow more accurate measurements by moving the waveforms over them.

Oscilloscopes are very useful tools for a variety of different applications, which contain varying voltage levels (which are known as ‘‘analog’’ voltage levels). They can be (and often are) used for digital logic applications but they are often not the best tool because digital waveforms only have two levels, when applied to electronics: digital signals are either a high voltage or a low voltage. The timing of the changes of these two voltage levels is more interesting to the designer.

So instead of thinking of digital waveforms in terms of voltage over time, in digital electronics, we prefer to think of them as states (High/Low, True/False, 1/0) over time and display them using a waveform diagram like the one shown in Fig. 1-17. When designing your digital electronics circuit, you will create a waveform diagram to help you understand how the logic states will be passed through the circuit; later, when you are debugging the circuit, you will be comparing what you actually see with this diagram to see if your assumptions about how the circuit would operate are correct. The different signals shown in Fig. 1-17 are samples of what you will see when you are designing your own application circuit.

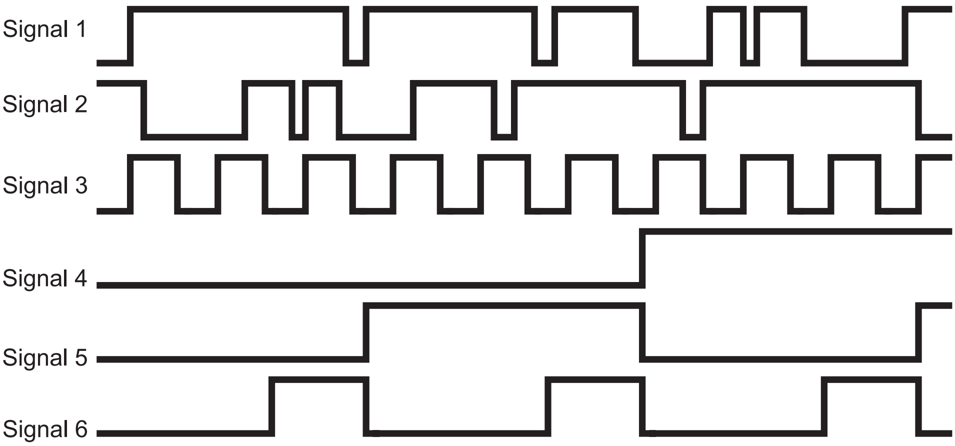

Fig. 1-17. Digital waveforms.

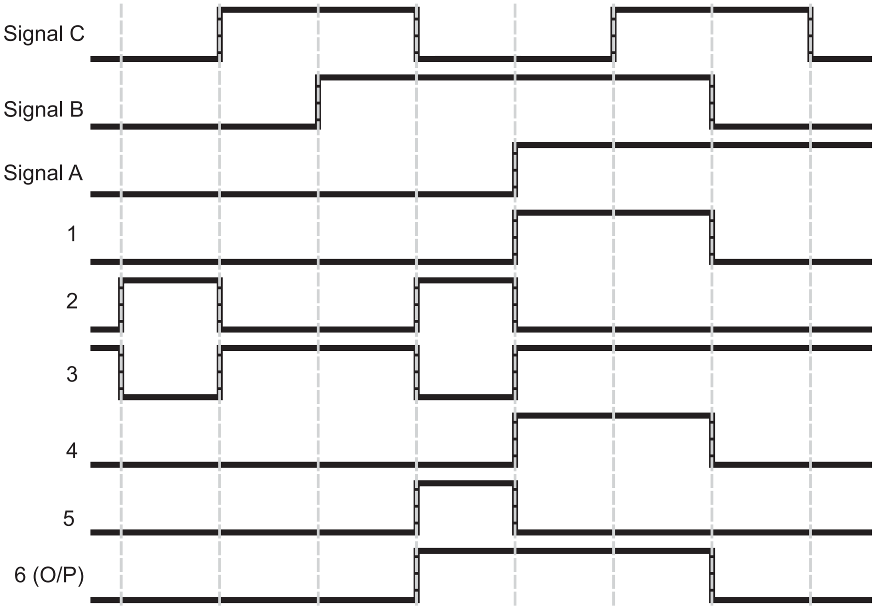

Fig. 1-18. Digital waveforms of Fig. 1-8 example combinatorial logic circuit.

The waveform diagram is the first tool that will help you optimize your circuit. Before writing up this section, I was planning on the diagrams I wanted to include with it and one was a waveform representation of the first example combinatorial logic circuit's operation from Table 1-9. The thin vertical lines indicate the edges of each state.

After drawing out Fig. 1-18, it was obvious that signals "1" and "4" (from the marked circuit diagram Fig. 1-8) were redundant. Looking back at the diagram for the circuit, I realized that the AND gate with output 4 and inverter with output 3 could be completely eliminated from the circuit – the output of AND gate 1 could be passed directly to the XOR gate (with output 6).

The waveform diagram shown in Fig. 1-18 is what I call an "idealized waveform diagram" and does not encompass what is actually happening in a physical circuit. Looking at Fig. 1-18, you will see that I have assumed that the switching time for the gates is instantaneous. In real components, switching time is finite, measurable and can have a significant impact to your application's ability to work. This is discussed in more detail in later chapters. Finally, this circuit does not allow for basic errors in understanding, such as what happens when multiple gate outputs are passed to a single gate input – your assumption of this type of case may not match what really happens in an actual circuit.

In this chapter, I have introduced you to the basic concepts of combinatorial logic circuits and the parts that make them up. In the next chapter, I will start working through some of the practical aspects of designing efficient digital electronic circuits.

Quiz

1. Which of the following statements is true?
   (a) Negative logic is the same as reverse psychology. You get somebody to do something by telling them to do what you don't want them to do
   (b) Using the logic definition, "A dog has four legs and fur", a cat could be accurately described as a dog
   (c) "High" and "Higher" are valid logic states
   (d) Assertions are the same as logic operations
2. Boolean arithmetic is a:
   (a) way to express logic statements in a traditional mathematical equation format
   (b) terrible fraud perpetrated by philosophers to disprove things they don't agree with
   (c) very difficult calculation used in astronomy
   (d) fast way to solve problems around the house
3. The truth table using "incrementing input" for the OR gate is correctly represented as:
   (a)

Input "A"	Input "B"	"OR" Output
False	True	True
True	False	True
False	False	False
True	True	True

(b)

Input “A”	Input “B”	“OR” Output
False	False	False
False	True	True
True	False	True
True	True	False

(c)

Input “A”	Input “B”	“OR” Output
False	False	False
False	True	True
True	False	True
True	True	True

(d)

Input “A”	Input “B”	“OR” Output
False	False	False
False	True	False
True	False	False
True	True	True

4. When writing a logic equation, which symbols are typically used to represent optional operations?
   (a) {and}
   (b) < and >
   (c) (and)
   (d) [and]

5. If the output of an Exclusive OR gate was passed to a NOT gate's input, the NOT gate output would be "True" if:
   (a) Input "A" was True and input "B" is False
   (b) There is only one input and the output would be True if the input was False
   (c) A dot was placed on the output of the Exclusive OR symbol
   (d) Both inputs were at the same state (either True or False)

6. Boolean arithmetic statements are similar to:
   (a) Verbal descriptions of what the logic is to do
   (b) HTML, the language used to program an internet web page
   (c) Simple mathematical equations
   (d) The holes punched into computer cards

7. When decoding a combinatorial logic circuit diagram, you
   (a) Write out the Boolean arithmetic equation for the function and list the output for each possible input
   (b) Start slamming your forehead on your desk
   (c) Give each gate's output a unique label and list their outputs for each changing circuit input as well as outputs for other gates in the circuit
   (d) Rearrange the gates in the diagram to help you understand what the function is doing

8. "Sum of product" combinatorial logic circuits are popular because:
   (a) They are the most efficient way of designing circuitry
   (b) Their operation can be quickly seen by looking at the circuit diagram
   (c) They dissipate less heat than other design methodologies
   (d) They are more robust and allow for more reliable product designs

9. When trying to debug a digital clock circuit, what tool is not recommended?
   (a) Truth tables
   (b) Boolean arithmetic
   (c) State lists
   (d) Graphical circuit diagrams

10. Waveform diagrams display:
    - (a) Logic state changes over time
    - (b) Switching times of digital electronic gates
    - (c) Problems with line impedance
    - (d) Voltage variances in a logic signal over time

CHAPTER 2

Effectively Optimizing Combinatorial Circuits

In the first chapter, I introduced you to the basic theory behind digital electronics: binary data is manipulated by six different simple operations. With this knowledge, you actually have enough information to be able to design very complex operations, taking a number of different bits as input. The problem with these circuits is that they will probably not be ‘‘optimized’’ in order to minimize the number of gates, the speed which the digital electronic circuit responds to the inputs and finally, whether or not the circuit is optimized for the technology that it will be implemented in.

These three parameters are the basic measurements used to determine whether or not a circuit is effectively optimized. The number of gates should be an obvious one and you should realize that the more gates, the higher the chip count and cost of implementing the circuit as well as the increased complexity in wiring it. Right now, connections between logic gates are just black lines on paper to you – but when you start trying to wire circuits that

Copyright © 2005 by The McGraw-Hill Companies, Inc. Click here for terms of use.

you have designed, you will discover first hand that simplifying the wiring of a circuit often reduces costs more than reducing the number of chips would indicate. Small improvements in the complexity of a circuit can have surprising cost ramifications when you look at the overall cost of the application. You may find that eliminating 1% of the gates in an application will result in as much as a 10–20% overall reductions in product cost. These savings are a result of being able to build the circuit on a smaller PCB or one which requires fewer layers (which can reduce the overall product cost dramatically). If the application is going to use a programmable logic technology, you may find that with the optimized circuit, lower cost chips can be substituted into the design. Fewer gates in an application also results in less power being dissipated by the circuit, requiring less cooling and a smaller power supply.

The speed that signals pass through gates is not infinite; standard TTL requires 8 billionths of a second (called a ‘‘nanosecond’’ and uses the abbreviation ‘‘ns’’) to pass a signal through a ‘‘NAND’’ gate. The term given to this time is known as the ‘‘gate delay’’. Halving the number of gates a signal has to pass through (which is halving the number of gate delays) will double the speed in which it can respond to a changing input. As you work with more complex circuits, you will discover that you will often have to optimize a circuit for speed or else you may have to use a faster (and generally more expensive) technology.

The last parameter, what I call ‘‘technology optimization’’, on the surface may seem more intangible than the other two parameters as well as have its measurements use the other two parameters, but when working with physical devices, it is the most important factor in properly optimizing your application. Before moving on and considering your circuit ‘‘done’’, you should look at how it will actually be implemented in the technology that you are using and look for optimizations that will reduce the actual number of gates and gate delays required by the application.

You can consider logic optimization to be a recursive operation, repeatedly optimizing all the different parameters and measurements. Once you have specified the required logic functions, you should look at how it will be implemented in the actual circuit. Once you have converted it to the actual circuit, you will then go back and look for opportunities for decreasing the number of gates, speeding up the time the signal passes through the gates and again look for technology optimizations. This will continue until you are satisfied with the final result.

To illustrate what I mean, in this chapter, I will look at a practical example, a simple home burglar alarm. In Fig. 2-1, I have drawn a very basic house, which has two windows, a door and power running to it. Sensors, on

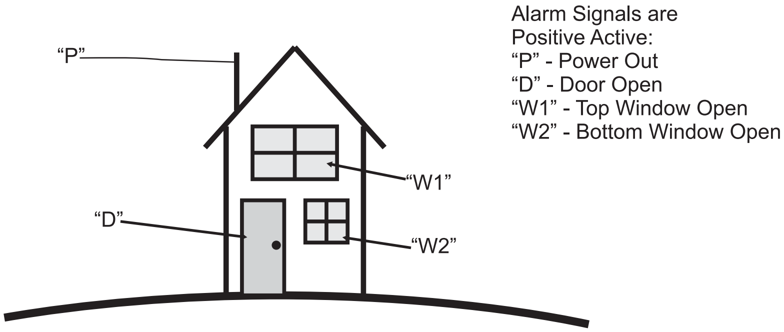

Fig. 2-1. Home alarm logic.

Table 2-1 Home alarm truth table.

P	D	W1	W2	Alarm Response
0	0	0	0	
0	0	0	1	
0	0	1	0	Sound Alarm
0	0	1	1	
0	1	0	0	
0	1	0	1	
0	1	1	0	Sound Alarm
0	1	1	1	
1	0	0	0	
1	0	0	1	Sound Alarm
1	0	1	0	Sound Alarm
1	0	1	1	Sound Alarm
1	1	0	0	
1	1	0	1	Sound Alarm
1	1	1	0	Sound Alarm
1	1	1	1	Sound Alarm

the windows, door and power are passed to an alarm system. When the alarm system was designed a table of the different possible combinations of inputs was generated (Table 2-1), with the combinations that would cause the alarm to sound indicated. As I have noted in Fig. 2-1, the alarm inputs are positive active, which means I can represent them as being active with a "1".

In this fictional house, I assumed that the upper window ("W1") should never be opened – if it were opened, then the alarm would sound. Along with this, I decided that if the power failed and either of the windows were opened, then the alarm failed; this would be the case where the power to the house was cut and somebody forced open the window. Table 2-1 shows the cases where the alarm should sound and you will notice that the cases where the alarm should sound are either a single event in the table, or a case where three are grouped together.

After building the table, you should also create a sum of products equation for the function:

$$
\begin{aligned}
\texttt{Alarm State} = {} & (\texttt{!P} \cdot \texttt{!D} \cdot \texttt{W1} \cdot \texttt{!W2}) \\
& + (\texttt{!P} \cdot \texttt{D} \cdot \texttt{W1} \cdot \texttt{!W2}) \\
& + (\texttt{P} \cdot \texttt{!D} \cdot \texttt{!W1} \cdot \texttt{W2}) \\
& + (\texttt{P} \cdot \texttt{!D} \cdot \texttt{W1} \cdot \texttt{!W2}) \\
& + (\texttt{P} \cdot \texttt{!D} \cdot \texttt{W1} \cdot \texttt{W2}) \\
& + (\texttt{P} \cdot \texttt{D} \cdot \texttt{!W1} \cdot \texttt{W2}) \\
& + (\texttt{P} \cdot \texttt{D} \cdot \texttt{W1} \cdot \texttt{!W2}) \\
& + (\texttt{P} \cdot \texttt{D} \cdot \texttt{W1} \cdot \texttt{W2})
\end{aligned}
$$

You could also draw a logic diagram using the gate symbols that I introduced in the first chapter. I found that this diagram was very complex and very difficult to follow. If you were to try it yourself, you would discover that the logic diagram would consist of 12 NOTs, 24 two input ANDs (knowing that a single four input AND can be produced from three two input ANDs) and seven two input OR gates with the maximum gate delay being eleven (the number of basic TTL gates the signal has to pass through). At first take, this alarm function is quite complex.

Looking at Table 2-1 and the sum of products equation, you will be hard pressed to believe that this home alarm circuit can be significantly optimized, but in this chapter, I will show how these four alarm inputs and eight alarm events can be reduced to fit in the most basic TTL chip there is.

Truth Table Function Reduction

I like to tell new circuit designers to approach optimizing a logic circuit by first looking for opportunities in its truth table. This may not seem like a useful tool (especially in light of Table 2-1), but it can be as effective a tool as any of the others presented in this chapter. It can also be used as a useful verification tool for making sure that an optimized logic circuit will perform the desired function. The drawback to the truth table function reduction is that it tends to be the most demanding in terms of the amount of rote effort that you will have to put into it.

Table 2-2 Gray code home alarm truth table.

1	1	1	0	Sound Alarm
1	0	1	0	Sound Alarm
1	0	1	1	Sound Alarm
1	0	0	1	Sound Alarm
1	0	0	0	

In the introduction to this chapter, the initial truth table I came up with didn't seem very helpful. The reason for this is something that I will harp upon throughout this book – listing logic responses to binary input is not very effective, because of the large number of states that can change at any given time. If you look at Table 2-1, you will see that going from the state where $P=0$, $D=W1=W2=1$ to $P=1$, $D=W1=W2=0$ involves the changing of four bits. While this is a natural progression of binary numbers and probably an intuitive way of coming up with a number of different input states, it is not an effective way to look at how a logic circuit responds to varying inputs.

A much better method is to list the output responses in a truth table that is ordered using Gray codes, as I have shown in Table 2-2. Gray codes are a numbering system in which only one bit changes at a time: they are explained in detail along with how they are generated in Chapter 4. When you are listing data, regardless of the situation, you should *always* default to using Gray code inputs instead of incrementing binary inputs, as I have shown in Table 2-1.

Taking this advice, I recreated the home alarm system truth table using Gray codes in Table 2-2. When you look at Table 2-2, you should notice that the "discontinuities" of Table 2-1 have disappeared. The bit patterns which "Sound Alarm" group together quite nicely.

Looking at each value which "Sound Alarm", you'll notice that each pair has three bits in common. To illustrate this, in Table 2-3, I have circled the bit which is different between each of the four pairs. In each of these

Table 2-3 Uncommon bits in “Sound Alarm” pairs.

P	D	W1	W2	Alarm Response
0	0	0	0	
0	0	0	1	
0	0	1	1	
0	x	1	0	Sound Alarm
0	1	1	1	
0	1	0	1	
0	1	0	0	
1	1	0	0	
1	1	x	1	Sound Alarm
1	x	1	0	Sound Alarm
1	0	x	1	Sound Alarm
1	0	0	0	

pairs, to sound the alarm we have very specific requirements for three bits, but the fourth bit can be in either state.

Another way of saying this is: for the alarm to sound, we don’t care what the fourth bit is and it can be ignored when we are determining the sum of products equation for the logic function. To indicate the “don’t care” bit, in Table 2-4, I have combined the bit pairs and changed the previously circled bits with an “x”. This “x” indicates that the bit can be in either state for the output to be true. By replacing the two truth table entries with a single one with the don’t care bit indicated by an “x” you should see that something magical is starting to happen.

The obvious observation is that the table is shorter, but you should notice that the number of events which “Sound Alarm” has been halved and they are less complex than the eight original events. The sum of products equation for the bits shown in Table 2-4 is:

$$\begin{aligned}\texttt{Alarm State} = {} & (!\texttt{P}\cdot\texttt{W1}\cdot!\texttt{W2})\\ & + (\texttt{P}\cdot\texttt{D}\cdot\texttt{W2})\\ & + (\texttt{P}\cdot\texttt{W1}\cdot!\texttt{W2})\\ & + (\texttt{P}\cdot!\texttt{D}\cdot\texttt{W2})\end{aligned}$$

This sum of products expression will require four NOT gates, eight AND gates and three OR gates and the maximum gate delay will be nine. This has reduced the total gate count to less than 50% of the original total and this logic equation will operate somewhat faster than the original.

This is pretty good improvement in the logic circuit. You should be asking yourself if we can do better. To see if we can do better, I rearranged the data in Table 2-4 so that the “Sound Alarm” events with common don’t care bits were put together and came up with Table 2-5.

When I put the “Sound Alarm” events that had the same don’t care bits together, I noticed that in each of these cases, two of the remaining bits were in common and one bit changed in the two events (which I circled in Table 2.5).

In Table 2-5, you may have noticed that the single changing bit of the original Gray code input sequence has been lost; this is not a problem. The Gray code sequence has served its purpose – it has indicated the initial input patterns which are common with its neighbors. In complex truth tables, you may have to rearrange bit patterns multiple times to find different

Table 2-5 Optimized home alarm truth table rearranged with don’t care event bits moved together.

1	x	x	1	Sound Alarm
1	0	0	0	

commonalities. When you do this, don't worry about "loosing data"; the important bit patterns are still saved in the active bit patterns.

Table 2-6 shows what happens when the second don't care bit is indicated. Since the two events which "Sound Alarm" do not have common don't care bits, we can't repeat this process any more. The two events from Table 2-6 can be written out as the sum of products:

$$\begin{aligned}\texttt{Alarm State} &= (\texttt{W1} \cdot !\texttt{W2}) \\ &\quad + (\texttt{P} \cdot \texttt{W2})\end{aligned}$$

This optimized "Alarm State" truth table has reduced our component count to one NOT gate, two AND gates and one OR gate and executes in five gate delays – quite an improvement from the original 43 gates and 11 gate delays!

Depending on how cynical you are, you might think that I "cooked up" this example to come up with such a dramatic improvement. Actually, the application shown here was my first attempt at coming up with a logic circuit to demonstrate how optimization operations of a logic circuit are performed; you will find similar improvements as this one when you start with a basic logic circuit and want to see how much you can reduce it.

Karnaugh Maps

Using truth tables is an effective but not very efficient method of optimizing digital logic circuits. A very clever French mathematician, Maurice Karnaugh (pronounced "carno") came up with a way to simplify the truth table optimization process by splitting the truth table inputs down the middle and arranging the two halves perpendicularly in order to display the relationships between bits more effectively. These modified truth tables are called "Karnaugh Maps" and are best suited for single bit output functions with three to six input bits.

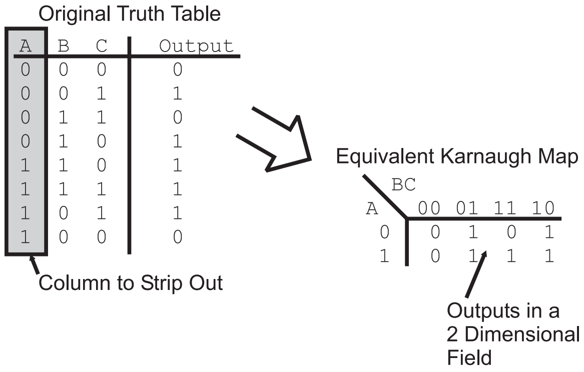
My description of what a Karnaugh map is may sound cursory, but it is actually very accurate. A standard truth table can be considered to be a single dimensional presentation of a logic function and when it is properly manipulated, relationship between active outputs can be observed as I showed in the previous section. The problem with this method is that it is fairly labor intensive and will burn up a lot of paper. Karnaugh maps present the data in a two-dimensional "field" which allows for quick scanning of active output bits against their inputs, to find basic relationships between them.

An example of converting a three input logic function from a truth table to a Karnaugh map is shown in Fig. 2-2. The initial logic function would be:

$$\begin{aligned}\mathtt{Output} = {} & (!\mathtt{A}\cdot !\mathtt{B}\cdot \mathtt{C}) + (!\mathtt{A}\cdot \mathtt{B}\cdot !\mathtt{C}) \\ & + (\mathtt{A}\cdot \mathtt{B}\cdot !\mathtt{C}) + (\mathtt{A}\cdot \mathtt{B}\cdot \mathtt{C}) \\ & + (\mathtt{A}\cdot !\mathtt{B}\cdot \mathtt{C})\end{aligned}$$

To create the Karnaugh map, I created a two by four matrix, with the rows being given the two different values for "A" and the columns given the four different values for "B" and "C". Note that the columns are listed as a two bit Gray code – this is an important feature of the Karnaugh map and, as I have pointed out, an important tool to being able to optimize a function.

Once the two axes of the Karnaugh map are chosen, the outputs from the truth table are *carefully* transferred from the truth table to the Karnaugh map. When transferring the outputs, treat the Karnaugh map as a two-dimensional array, with the "X" dimension being the inputs which



A	B	C	Output
0	0	0	0
0	0	1	1

weren't stripped out and the "Y" dimension being the inputs which were stripped out from the truth table. When you are first starting out, this will be an operation in which you will tend to make mistakes because it is unfamiliar to you. To make sure you understand the process, it is a good idea to go back and convert your Karnaugh map into a truth table and compare it to your original truth table.

When you have created the Karnaugh map for your function, it is a good idea to either photocopy it or write it out in pen before going on. I am suggesting this action because, just as you did with the truth table, you are going to circle outputs which have the same unchanging bit patterns. As you circle the outputs, chances are you are not going to see the most effective groups of bits to circle together, or you will find that you have made a mistake in circling the bits. A photocopy or list in ink will allow you to try again without having to redraw the Karnaugh map.

For the example shown in Fig. 2-2, the Karnaugh map has three circles put on it, as shown in Fig. 2-3. Each circle should result in combining two input sets together and making at least one bit into a "don't care".

Correctly circling bits can be difficult to understand, but there are a few rules that can be applied to it. First, each circle *must* be around a power of two number of bits – you cannot circle three bits (as shown in Fig. 2-4 for this example). Secondly, it is not a problem if circles overlap over specific bits. I should point out that there is the case for redundant circles (Fig. 2-5). If a circle is drawn and all the circled bits are enclosed in another circle, then the enclosed circle is redundant. Thirdly, remember that when you are circling bits that you want to circle a power of two number of bits, not just two. In Fig. 2-6, I have modified the three bit Karnaugh map with the outputs at A = 0 and B = C = 1 and A = 1 and B = C = 0 being a "1"

and found that I could circle two groups of four bits. In each of these cases, I have made two bits "don't care".

Finally, saying that a Karnaugh map is like a two-dimensional array is inaccurate – it is actually a continuum unto itself, with the tops and sides being connected. When you draw out your Karnaugh map, you may find that the bits which can be circled (meaning ones with similar patterns) are on opposite ends of the Karnaugh map. This is not a problem as long as there are matching bits.

Once you have the outputs circled, you can now start writing out the optimized equation. As an exercise, you might want to look at the example Karnaugh maps in Figs. 2-3, 2-6 and 2-7. The output equations for these figures are:

$$\mathtt{Output}_{2.03} = (!\mathtt{B} \cdot \mathtt{C}) + (\mathtt{B} \cdot !\mathtt{C}) + (\mathtt{A} \cdot \mathtt{C})$$
$$\mathtt{Output}_{2.06} = \mathtt{A} \cdot \mathtt{C}$$
$$\mathtt{Output}_{2.07} = (!\mathtt{B} \cdot \mathtt{C}) + (\mathtt{B} \cdot !\mathtt{C}) + (\mathtt{A} \cdot !\mathtt{C})$$

Fig. 2-8. Home alarm truth table to Karnaugh map.

In this chapter, I wanted to show how the different optimizing tools are used for the home alarm system presented in the chapter introduction. The alarm system's functions can be optimized using the Karnaugh map shown in Fig. 2-8. In Fig. 2-8, I have drawn the circles around the two groups of four active output bits which are in common and result in the logic equation

$$\texttt{Alarm Response} = (\texttt{P} \cdot \texttt{W2}) + (\texttt{W1} \cdot \texttt{!W2})$$

which is identical to the equation produced by the truth table reduction and a lot less work.

Before going on, I want to just say that once you are comfortable with Karnaugh maps, you will find them to be a fast and efficient method of optimizing simple logic functions. Becoming comfortable and being able to accurately convert the information from a truth table to a Karnaugh map will take some time, as will correctly circling active outputs to produce the optimized sum of products circuit. Once you have mastered this skill, you will find that you can go directly to the Karnaugh map from the requirements without the initial step of writing out the truth table.

Boolean Arithmetic Laws

One of the ways of optimizing circuits is look through their output equations and try to find relationships that you can take advantage of using the rules and laws in Table 2-7. These rules should be committed to memory as quickly as possible (or at least written down on a crib sheet) to help you with

Table 2-7 Boolean arithmetic laws and rules.

Rule/law	Boolean arithmetic example
AND identity function	$A \cdot 1 = A$
OR identity function	$A + 0 = A$
Output reset	$A \cdot 0 = 0$
Output set	$A + 1 = 1$
Identity law	$A = A$
AND complementary law	$A \cdot !A = 0$
OR complementary law	$A + !A = 1$
AND idempotent law	$A \cdot A = A$
OR idempotent law	$A + A = A$
AND commutative law	$A \cdot B = B \cdot A$
OR commutative law	$A + B = B + A$
AND associative law	$(A \cdot B) \cdot C = A \cdot (B \cdot C) = A \cdot B \cdot C$
OR associative law	$(A + B) + C = A + (B + C) = A + B + C$
AND distributive law	$A \cdot (B + C) = (A \cdot B) + (A \cdot C)$
OR distributive law	$A + (B \cdot C) = (A + B) \cdot (A + C)$
De Morgan's NOR theorem	$!(A + B) = !A \cdot !B$
De Morgan's NAND theorem	$!(A \cdot B) = !A + !B$

optimizing logic equations without the need of truth tables or Karnaugh maps. Many of these rules and laws will seem self-evident, but when you are working at optimizing a logic equation in an exam, it is amazing what you will forget or won't seem that obvious to you.

When I talk about using the laws and rules in Table 2-7 to simplify a logic equation, I normally use the term "reduce" instead of "optimize". The reason for thinking of these operations as a reduction is due to how much the logic equation shrinks as you work through it, trying to find the most efficient sum of products expression.

The two identity functions are used to indicate the conditions where an input value can pass unchanged through an AND or OR gate. The output set, reset and complementary laws are used to output a specific state when a value is passing through an AND or OR gate. The idempotent laws can be summarized by saying that if an input passes through a non-inverting gate, its value is not changed.

The remaining laws – commutative, associative and distributive – and De Morgan's theorems are not as trivial and are extremely powerful tools when you have a logic equation to optimize. The commutative laws state that the inputs to AND and OR gates can be reversed, which may seem obvious, but when you have a long logic equation that is written in an arbitrary format (not necessarily in sum of product format), you can get confused very easily as to what is happening. It's useful to have a law like this in your back pocket to change the logic equation into something that you can more easily manipulate.

To demonstrate the operation of these laws, we can go back to some of the logic circuits described in the Karnaugh map examples of the previous section. Looking at Fig. 2-3, the initial sum of products logic equation would be:

$$\begin{aligned}\texttt{Output} = {} & (!\texttt{A} \cdot !\texttt{B} \cdot \texttt{C}) + (!\texttt{A} \cdot \texttt{B} \cdot !\texttt{C}) + \\ & (\texttt{A} \cdot !\texttt{B} \cdot \texttt{C}) + (\texttt{A} \cdot \texttt{B} \cdot \texttt{C}) + \\ & (\texttt{A} \cdot \texttt{B} \cdot !\texttt{C})\end{aligned}$$

Using the AND associative law, I can rewrite this equation with the A term separate from the B and C terms to see if there are any cases where the B and C terms are identical.

$$\begin{aligned}\texttt{Output} = {} & !\texttt{A} \cdot (!\texttt{B} \cdot \texttt{C}) + !\texttt{A} \cdot (\texttt{B} \cdot !\texttt{C}) + \\ & \texttt{A} \cdot (!\texttt{B} \cdot \texttt{C}) + \texttt{A} \cdot (\texttt{B} \cdot \texttt{C}) + \\ & \texttt{A} \cdot (\texttt{B} \cdot !\texttt{C})\end{aligned}$$

By doing this, I can see that the inside terms of the first and third products are identical. Along with this, I can see that the second and fifth products are also identical. Using the OR distributive law, I can combine the first and third terms like:

$$\begin{aligned}&!\mathtt{A}\cdot(!\mathtt{B}\cdot\mathtt{C})+\mathtt{A}\cdot(!\mathtt{B}\cdot\mathtt{C})\\&\quad=(!\mathtt{A}+\mathtt{A})\cdot(!\mathtt{B}\cdot\mathtt{C})\end{aligned}$$

Using the OR complementary law, I know that A OR !A will always be true. This is actually a clear and graphic example of the "don't care" bit; regardless of the value of this bit, the output will be true so it can be ignored. The partial equation of the two terms reduces to:

$$\begin{aligned}&(!\mathtt{A}\cdot!\mathtt{B}\cdot\mathtt{C})+\mathtt{A}\cdot(!\mathtt{B}\cdot\mathtt{C})\\&\quad=\mathtt{1}\cdot(!\mathtt{B}\cdot\mathtt{C})\end{aligned}$$

The 1 ANDed with !B AND C can be further reduced using the AND identity law (1 AND A equals A):

$$\begin{aligned}&!\mathtt{A}\cdot(!\mathtt{B}\cdot\mathtt{C})+\mathtt{A}\cdot(!\mathtt{B}\cdot\mathtt{C})\\&\quad=(!\mathtt{B}\cdot\mathtt{C})\end{aligned}$$

This can be repeated for the second and fifth terms:

$$\begin{aligned}&(!\mathtt{A}\cdot\mathtt{B}\cdot!\mathtt{C})+(\mathtt{A}\cdot\mathtt{B}\cdot!\mathtt{C})\\&\quad=(\mathtt{B}\cdot\mathtt{C})\end{aligned}$$

If you go back to the original logic equation, you will see that the fourth term $(A\cdot B\cdot C)$ has not been reduced by combining it with another term. It can actually be paired with the third term $(A\cdot!B\cdot C)$ by rearranging the two terms (using the AND commutative law) so that part of the terms operating on two bits are in common $(A\cdot C)$. Once this is done, the third and fourth terms can be reduced as:

$$\begin{aligned}&(\mathtt{A}\cdot!\mathtt{B}\cdot\mathtt{C})+(\mathtt{A}\cdot\mathtt{B}\cdot!\mathtt{C})\\&\quad=(\mathtt{A}\cdot!\mathtt{C})\end{aligned}$$

After doing this work, the optimized or reduced sum of product logic equation for this function is

$$\mathtt{Output}=(!\mathtt{B}\cdot\mathtt{C})+(\mathtt{B}\cdot!\mathtt{C})+(\mathtt{A}\cdot\mathtt{C})$$

which is identical to what was found using the Karnaugh map.

Looking at the reduced logic equation, you should have noticed that there are two terms that will output a "1" at the same time $((!B\cdot C)$ and $(A\cdot C)$ with $A=1$, $B=0$ and $C=1$). This is not a problem because the OR gate (even though the symbol that I use is a "+") will only output a 1, regardless of how many true inputs it has. This was mentioned when the

Karnaugh maps were presented, but I wanted to reinforce that the same issue is present when you are reducing logic equations.

Before moving on, let's go back to the home alarm logic equation and see if it can be reduced in the same way as the example above. Starting with the sum of products logic equation:

$$
\begin{aligned}
\texttt{Alarm State} = {} & (\texttt{!P} \cdot \texttt{!D} \cdot \texttt{W1} \cdot \texttt{!W2}) \\
& + (\texttt{!P} \cdot \texttt{D} \cdot \texttt{W1} \cdot \texttt{!W2}) \\
& + (\texttt{P} \cdot \texttt{!D} \cdot \texttt{!W1} \cdot \texttt{W2}) \\
& + (\texttt{P} \cdot \texttt{!D} \cdot \texttt{W1} \cdot \texttt{!W2}) \\
& + (\texttt{P} \cdot \texttt{!D} \cdot \texttt{W1} \cdot \texttt{W2}) \\
& + (\texttt{P} \cdot \texttt{D} \cdot \texttt{!W1} \cdot \texttt{W2}) \\
& + (\texttt{P} \cdot \texttt{D} \cdot \texttt{W1} \cdot \texttt{!W2}) \\
& + (\texttt{P} \cdot \texttt{D} \cdot \texttt{W1} \cdot \texttt{W2})
\end{aligned}
$$

We can bring out the "P" values from the products and look for similarities in the remaining bracketed values and combine them using the associative, distributive, complementary and AND identity laws. I can see that the first and fourth, second and seventh can be combined, resulting in the logic equation:

$$
\begin{aligned}
\texttt{Alarm State} = {} & (\texttt{!D} \cdot \texttt{W1} \cdot \texttt{!W2}) \\
& + (\texttt{D} \cdot \texttt{W1} \cdot \texttt{!W2}) \\
& + (\texttt{P} \cdot \texttt{!D} \cdot \texttt{!W1} \cdot \texttt{W2}) \\
& + (\texttt{P} \cdot \texttt{!D} \cdot \texttt{W1} \cdot \texttt{W2}) \\
& + (\texttt{P} \cdot \texttt{D} \cdot \texttt{!W1} \cdot \texttt{W2}) \\
& + (\texttt{P} \cdot \texttt{D} \cdot \texttt{W1} \cdot \texttt{W2})
\end{aligned}
$$

Bringing "W1" to the forefront allows the combination of the third and fourth and fifth and sixth terms of the logic equation above, resulting in the new equation:

$$
\begin{aligned}
\texttt{Alarm State} = {} & (\texttt{!D} \cdot \texttt{W1} \cdot \texttt{!W2}) \\
& + (\texttt{D} \cdot \texttt{W1} \cdot \texttt{!W2}) \\
& + (\texttt{P} \cdot \texttt{!D} \cdot \texttt{W2}) \\
& + (\texttt{P} \cdot \texttt{D} \cdot \texttt{W2})
\end{aligned}
$$

We have eliminated half the terms and, of those remaining, they are 25% smaller. Looking at the new logic equation, we can see that by combining the first and second terms (making "D" a don't care bit in the process)

Table 2-8 Testing optimized home alarm logic equation.

P	D	W1	W2	Alarm	W1 ● !W2	P ● W2	OR
0	0	0	0	0	0	0	0
0	0	0	1	0	0	0	0
0	0	1	1	0	0	0	0
0	0	1	0	1	1	0	1
0	1	1	0	1	1	0	1
0	1	1	1	0	0	0	0
0	1	0	1	0	0	0	0
0	1	0	0	0	0	0	0
1	1	0	0	0	0	0	0
1	1	0	1	1	0	1	1
1	1	1	1	1	0	1	1
1	1	1	0	1	1	0	1
1	0	1	0	1	1	0	1
1	0	1	1	1	0	1	0
1	0	0	1	1	0	1	0
1	0	0	0	0	0	0	0

and combining the third and fourth terms ("D" again is the don't care bit) we end up with:

$$\texttt{Alarm State} = (\texttt{W1} \cdot \texttt{!W2}) + (\texttt{P} \cdot \texttt{W2})$$

which is, again, the logic equation found by optimizing the function using truth tables or Karnaugh maps.

Personally, I tend to optimize logic equations using the Boolean arithmetic laws and rules listed in Table 2-7. Once a reduced sum of products equation has been produced, I then go back and compare its outputs in a truth table with the required outputs. In doing this, I present the values for each product (AND) and the final sum (OR) in separate columns, as shown in Table 2-8.

Optimizing for Technology

If you review the laws in Table 2-7 and correlate them to the text in the previous section, you'll see that I missed the last two (De Morgan's theorem). These two laws are not typically used during basic logic equation reduction because they typically involve converting part of an equation into an NAND or NOR gate, which is important when finally implementing a logic function in actual electronics. Another important aspect of optimizing for technology is adding functions out of the leftover gates in your circuit; by looking at how differently a logic circuit could be implemented, you may be able to add functionality to your circuit, without adding any cost to it.

Table 2-9 XOR gate truth table.

A	B	A ˆ B
0	0	0
0	1	1
1	1	0
1	0	1

So far in the book, I haven't discussed the "Exclusive OR" (XOR) gate in a lot of detail, but it is vital for implementing binary adders, as I will show you later in the book. In the first chapter, I presented the XOR gate with the truth table shown in Table 2-9.

You should probably be able to create the logic equation for the XOR table as:

$$\texttt{Output} = (!\texttt{A} \cdot \texttt{B}) + (\texttt{A} \cdot !\texttt{B})$$

which does not seem like a very likely candidate for optimization. Similarly, you probably would have a hard time believing that the following logic equation would perform the same function:

$$\texttt{Output} = !((\texttt{A} \cdot \texttt{B}) + !(\texttt{A} + \texttt{B}))$$

But, using De Morgan's theorem as well as the other rules and laws from Table 2-7, I can go through the manipulations shown in Table 2-10 to show that they are equal, as well as count out the gates required by intermediate steps to give you a list of different implementations of the XOR gate. Each intermediate step in Table 2-10 is an implementation of the XOR gate that you could implement using the number of gates listed to the right of the terms.

It's interesting to note that a total of five gates is required for each implementation – this is not something that you can count on when you are working at optimizing a circuit.

The basic gate used in TTL is the "NAND" gate: this means that the three basic gates (AND, OR and NOT) are built from multiples of it, as I've shown in Fig. 2-9. The basic gate for CMOS is the NOR gate, and Fig. 2-10 shows how the three basic gates are implemented for it. The three gate NAND and NOR equivalencies for the OR and AND gates, respectively, are perfect examples of De Morgan's theorem in operation. These implementations

Table 2-10 Different implementations of the XOR gate.

Terms	NOTs	ANDs	ORs	NANDs	NORs
$(!A \cdot B) + (A \cdot !B)$	2	2	1	0	0
$!(!(!A \cdot B) \cdot !(A \cdot !B))$	2	0	0	3	0
$!((A + !B) \cdot (!A + B))$	2	0	2	1	0
$!((A \cdot B) + (!A \cdot !B))$	2	2	0	0	1
$!((A \cdot B) + !(A + B))$	0	1	0	0	2

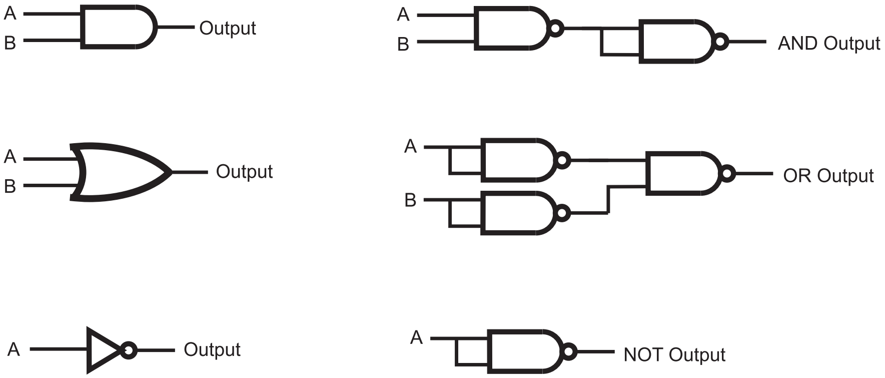

Fig. 2-9. Implementing the three basic gates using NAND gates.

can be checked against De Morgan's theorem and the rules and laws presented in Table 2-7.

By understanding how gates are implemented in chips, we can now look at how to optimize the gates to provide the fastest possible operation of the logic function. Using the example of the XOR gate, we can graphically show how the gate is implemented using ANDs, ORs and NOTs and how these gates are implemented as NAND gates in TTL chips (Fig. 2-11).

Looking at the bottom logic diagram of Fig. 2-11, you can see that there are two sets of NAND gates wired as inverters together. Going back to Table 2-7, we can see that a doubly inverted signal is the same signal, so we can eliminate these two sets of NOT gates, as shown in Fig. 2-12. The resulting XOR circuit will pass signals through three NAND gates, which

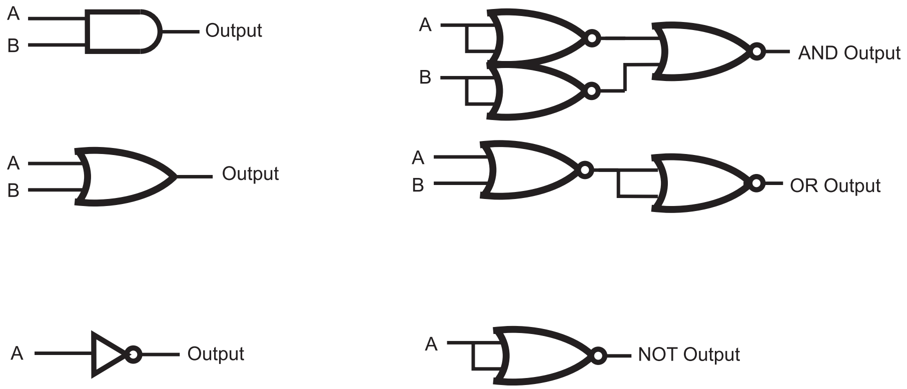

Fig. 2-10. Implementing the three basic gates using NOR gates.

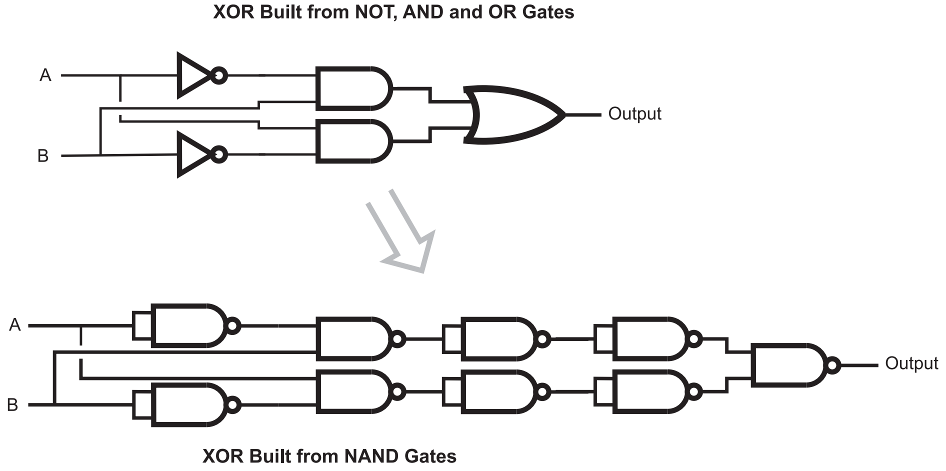

XOR Built from NOT, AND and OR Gates

XOR Built from NAND Gates

Fig. 2-11. XOR gate built from sum of products equation and converted to NAND gates.

counts as three “gate delays”. This is an example of what I call “technology optimization”: the logic circuit has been reduced to its bare minimum, taking advantage of the operation of the basic logic gates that make up the technology that it is implemented in.

Before moving on, I want to take one more look at the home alarm circuit that has been discussed throughout this chapter. I made a pretty bold statement at the start of the chapter, saying that it could be reduced to fit into the most basic TTL chip available – let’s see how honest I was being.

The (repeatedly) optimized logic equation for the home alarm system was:

$$\texttt{Alarm State} = (\texttt{W1} \cdot \texttt{!W2}) + (\texttt{P} \cdot \texttt{W2})$$

which could be first implemented in two AND, one OR and one NOT gate, as shown in Fig. 2-13 and converted to just NAND gates. You may have noted in Fig. 2-13 the remarkable similarity between the home alarm logic diagram and the XOR logic diagram – as I've shown in Fig. 2-14, the logic function reduces to just four NAND gates (one less than the XOR gate built out of NAND gates).

The final home alarm logic function requires four two input NAND gates – which is just what the 7400, the most basic TTL chip, provides. Every TTL chip, except for this one and a derivative revision, has more than four

gates built into them because they provide additional functions requiring multiple NAND gates. I was not exaggerating when I said that the home alarm logic function could be reduced to the most basic TTL chip available. In the next chapter, I will introduce you to the operation of TTL chips that provide the basis for digital electronic logic functions.

Quiz

1. The three parameters that are used to measure the optimization of a digital electronic circuit are:
   (a) Cost, speed and complexity
   (b) Gate delay, gate count and technology optimization
   (c) Gate count, number of gate delays a signal must pass through and technology optimization
   (d) Gate count, number of connections a signal must pass through and technology optimization
2. If TTL logic has a gate delay of 8 ns and the signal passing through an XOR gate built from NAND gates has to go through 9 gates and the shortest path is five gate delays, the time required for a signal to pass through the gates is:
   (a) 40 ns
   (b) 8 ns

(c) indeterminate
(d) 24 ns

3. When writing out a truth table, the inputs should be listed:
   (a) Using a "Gray code"
   (b) Using a "binary progression"
   (c) In alphabetical order
   (d) In order of importance

4. The "don't care" bit in a truth table is:
   (a) Indicated by a "dc" and replaces the common bits in two true sets of inputs
   (b) Indicated by an "x" and replaces the common bits in two true sets of inputs
   (c) Indicated by a "dc" and replaces the uncommon bits in two true sets of inputs
   (d) Indicated by an "x" and replaces the uncommon bits in two true sets of inputs

5. When optimizing a logic function you can expect:
   (a) That the number of chips that are required is reduced from the initial design
   (b) That the optimized function runs faster than the initial design
   (c) Cheaper chips can be used than in the initial design
   (d) Answers (a) through (c) are all possible and it might not be able to optimize the circuit from the initial sum of products equation

6. Karnaugh maps are:
   (a) Tools designed to help you find your way around a digital electronic circuit
   (b) A tool that will help you optimize a logic function
   (c) The most efficient method of optimizing logic fuctions
   (d) Hard to understand but must be used in every logic function design

7. The sum of products logic equation

   $$\texttt{Output} = (\texttt{A} \cdot \texttt{!B} \cdot \texttt{C}) + (\texttt{!A} \cdot \texttt{!B} \cdot \texttt{C})$$

   can be reduced to:
   (a) A · C
   (b) !A · !B
   (c) C · !B
   (d) C

8. Which of the following pairs of Boolean arithmetic laws cannot be used together?
   - (a) Identity and De Morgan's theorem
   - (b) Associative and idempotent
   - (c) Complementary and commutative
   - (d) All the laws and rules can be used together

9. The NAND equivalent to an AND gate is:
   - (a) Built from two NAND gates and requires two gate delays for a signal to pass through
   - (b) Built from three NAND gates and requires two gate delays for a signal to pass through
   - (c) Built from three NAND gates and requires three gate delays for a signal to pass through
   - (d) Built from one NAND gate as well as a NOT gate and requires two gate delays for a signal to pass through

10. Technology optimization is defined as:
    - (a) Designing the circuit which uses the fewest number of chips and signals pass through it as fast as possible
    - (b) Implementing logic functions to take advantage of the base logic of the logic technology used as well as using any leftover gates
    - (c) Finding the most efficient digital electronic technology to use for the application
    - (d) Designing circuitry that dissipates the least amount of heat to perform a desired function

CHAPTER 3

Creating Digital Electronic Circuits

In the previous chapters, I introduced you to the basic Boolean arithmetic theory behind decoding and design combinatorial circuits; binary data is manipulated by simple operations to produce a desired output. Before going on and showing you how these basic operations are extended to create complicated functions and products, I want to take a step back and look at basic electrical theory and semiconductor operation and how they are applied to digital electronics. While digital electronics work with ‘‘ones and zeros’’, it is still built from the basic electronic devices that are outlined in the beginning of this chapter. It is impossible to work successfully with digital electronics without understanding basic electrical theory and how simple electronic devices work.

For many people, this chapter will be a review, but I still urge you to read through this chapter and answer the quiz at the end of it. While you may be familiar with electrical rules and device operation, you may not be so comfortable understanding how they are used to create digital electronics.

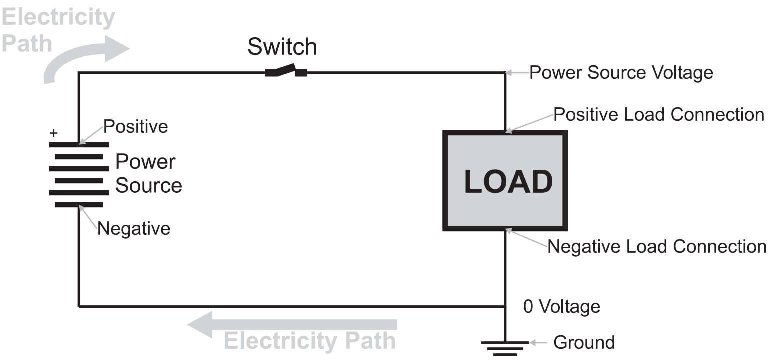

Fig. 3-1. Basic circuit diagram.

The most basic rule of electricity is that it can only move in a ‘‘closed circuit’’ (Fig. 3-1) in which a ‘‘power source’’ passes electricity to and then pulls it from a *load*. The power source has two connections that are marked with a ‘‘+’’ (‘‘positive’’) and ‘‘−’’ (‘‘negative’’) markings to indicate the ‘‘polarity’’ of the power source and the power source symbol consists of a number of pairs of parallel lines with the longer line in each pair representing the positive connection. The black lines connecting the power source to the load represent wires. When basic electricity is presented, this ‘‘load’’ is most often a lightbulb, because it turns on when electricity passes through it. As well as being a lightbulb, the load can be electrical motors, heater elements or digital electronic chips or any combination of these devices.

In the ‘‘electrical circuit’’ (or ‘‘schematic diagram’’) shown in Fig. 3-1 you can see that I have included a *switch,* which will *open* or *close* the circuit. When the switch is closed, electricity will flow through from the power source, to the load and back. If the switch is open or the wires connecting the power source to the load are broken, then electricity will not flow through the load.

As you are probably aware, electricity consists of electrons moving from the power source through the wires to the load and back to the power source. There are actually two properties of electricity that you should be aware of and they are analogous to the two properties of water flowing through a pipe. *Voltage* is the term given to the *pressure* placed on the electrons to move and *current* is the number of electrons passing by a point at a given time.

In the early days of electrical experimentation, it was Benjamin Franklin who postulated that electricity was a fluid, similar to water. As part of this supposition, he suggested that the electrical current flowed from the positive power supply connection to the negative. By suggesting that electrical current flowed from positive to negative, he started drawing electrical wiring diagrams or *schematics* (like the one in Fig. 3-1) with the electrical energy at the positive power supply connection being at the highest state. As the electrical current ‘‘flowed down’’ the page to the negative connection of the power supply, the energy of the electricity decreased. This method of drawing electrical circuits is clever and intuitive and caught on because it described what was happening in it.

Unfortunately, Franklin’s suggestion that electrical current flowed from the positive to negative connections of the power source through the load was wrong. As we now know, electrons that make up electricity flow from the negative to positive connections of the power supply. This discovery was made about 150 years after his kite in a lightning storm experiment, so the notion that electrical current flowed from positive to negative was widely accepted and was never really challenged. For this reason, you should keep in mind that ‘‘electrical current flow’’ takes place in the opposite direction to ‘‘electron flow’’ in electrical circuits. This point trips many people new to electronics and I should state emphatically that the direction of current flow follows Franklin’s convention.

Looking at the bottom right hand corner of Fig. 3-1, you will see a funny set of lines attached to the wiring lines – this is the circuit’s ‘‘ground’’ connection. The circuit ground is another invention of Benjamin Franklin. If there is ever a large amount of electricity that finds its way into the circuit, it will have an ‘‘escape route’’ to prevent damage to the circuit’s components or hurting anybody working with the circuit. The ground connection was literally a metal spike driven into the ground and connected to a home or barn’s lightning rod. In modern structures, the ‘‘ground’’ is a connection to the metal pipe bringing in water.

Another term commonly used for a circuit’s wire connections or wiring lines is ‘‘nets’’. The term originated when circuit analysis was first done on complex *networks* of wiring. It is used to describe the individual wiring connections in a circuit. I will use this term along with ‘‘wiring’’ and ‘‘lines’’ in this book interchangeably.

Like power supplies, many load devices also have connections that are marked with a positive (‘‘+’’) and negative (‘‘–’’) connections. When discussing the positive and negative connections of a basic two-wire load device, I like to use the terms, *anode* and *cathode* to describe the positive and negative connections of the load, respectively. The load’s anode must always be connected to the positive terminal of the power supply and the load’s cathode must always be connected to the negative terminal of the power supply. Reversing these connections may result in the device not working or even going so far as literally ‘‘burning out’’. To keep the terms anode and cathode straight, I remember that a “cathode ray tube” (i.e. your TV set) involves firing electrons, which are negative, at a phosphorus screen.

More complex load devices, like logic chips, also have positive and negative connections, but these connections are normally called *Vcc* or *Vdd* for the positive connection or *Gnd* and *Vss* for the negative (ground) connections.

When working with most basic digital electronic circuits, the binary value “1” is applied to a high, positive voltage (usually close to the voltage applied to the Vcc or Vdd pin of the chip). The binary value “0” is applied to low voltage (very close to the ground voltage level of the chip). This is generally considered intuitively obvious and can be easily remembered that a “1” input is the same as connecting an input to the power supply and a “0” input is the same as connecting an input to ground (resulting in “0” voltage). Similarly for outputs, when a “1” is output, you can assume that the chip can turn on a light. These conventions are true for virtually all basic electronic logic technologies; when you get into some advanced, very high speed logic, you may find that chips are designed with different operating conditions.

To simplify wiring diagrams, you will see many cases where the positive power connection and negative power connection are passed to terminal symbols to simplify the diagram and avoid the additional complexity of power and ground lines passing over the page and getting confused with the circuit “signal” lines.

When you are wondering how to connect an electronic device to its power supply, you can use Table 3-1 as a quick reference.

Table 3-1 Power wiring reference.

Positive (“+”) connection	**Negative (“−”) connection**	**Comments**
Red wire	Black wire	Wires connected to and between devices
Anode	Cathode	Diodes and capacitors
Vcc	Gnd	TTL
Vdd	Vss	CMOS

Basic Electronic Laws

Before starting to build your own digital electronics circuits, you should make sure that you are very familiar with the basic direct current electricity laws that govern how electricity flows through them. Don't worry if you have not yet been exposed to any direct current electrical theory, it's actually pretty simple and in the introduction to this chapter, I gave you a quick run down of how direct current circuits operate. I'm sure you were able to get through that without too many problems.

To make sure that you are clear on what *direct current* (also known as "DC") is, it consists of electricity running in a single direction without any changes. *Alternating current* ("AC") continuously changes from positive to negative (as shown in Fig. 3-2). AC is primarily used for high-power circuitry and not for any kind of digital electronics, except as something that is controlled by it. Digital electronics is powered by direct current, which consists of a fixed voltage which does not change level or polarity, as AC does.

As I indicated in the introduction, there are two components to electricity: *voltage* is the "pressure" applied to the electrons and *current* is the number of electrons that flow past a point or a set amount of time. I use the terms "pressure" and "flow" to help you visualize electricity moving in a wire as being the same as water flowing through a pipe. Using a water/pipe analogy can help you visualize how electricity moves and changes according to the conditions it is subjected to.

It should be obvious that the more pressure you apply to water in a pipe, the more water will pass through it. You can demonstrate this with a garden hose and a tap. By partially closing the tap, you are restricting the flow of the water coming from it, and the stream will not go very far from the end of the hose and very little water will flow out. When you completely open the tap, the water will spray out considerably further and a lot more water will be passing out the end of the hose. Instead of saying that you are closing the tap,

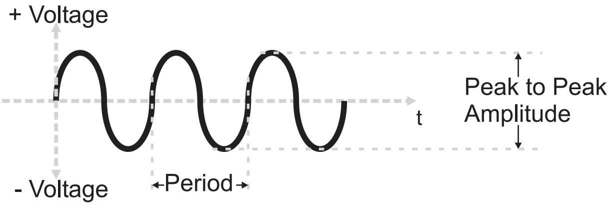

Fig. 3-2. Alternating current.

why don't you think of the closing tap as resisting the flow of water through the pipe and into the hose? This is exactly analogous to the *load* in a circuit converting electrical energy into something else. Electricity coming out of the load will be at a lower pressure (or voltage) than the electricity going into the load and the amount of current will be reduced as well.

When you visualized the pipe/tap/hose analogy, you probably considered that all the resistance in the circuit was provided by the tap – the pipe and the hose did not impede the water's flow in any way. This is also how we model how electricity flows in wires; the wires do not cause a drop in voltage and do not restrict the amount of current that is flowing in them. If you think about it for a moment, you will probably realize that this assumption means that the wires are ''superconductors''; any amount of electricity and at any voltage could be carried in the wires without any loss.

The wires that you use are certainly not superconductors, but the assumption that the wires do not impede the flow of electricity is a good one as their resistance in most circuits is usually negligible. By assuming that the wires are superconductors, you can apply some simple rules to understand the behavior of electricity in a circuit.

Going back to the original schematic diagram in this chapter (see Fig. 3-1), we can relate it to the pipe/tap/hose example of this section. The circuit's power supply is analogous to the pipe supplying water to the tap (which itself is analogous to the electrical circuit's load). The hose provides the same function as the wires bringing the electrical current back to the power supply.

In the pipe/tap/hose example, you should be able to visualize that the amount of water coming through the hose is dependent on how much the tap impedes the water flow from the pipe. It should be obvious that the less the tap impedes the water flow, the more water will come out the hose. Exactly the same thing happens in an electrical circuit; the ''load'' will impede or ''resist'' the flow of electricity through it and, in the process, take energy from the electricity to do something with it.

The most basic load that can be present in a circuit is known as the ''resistor'' (Fig. 3-3), which provides a specified amount of resistance,

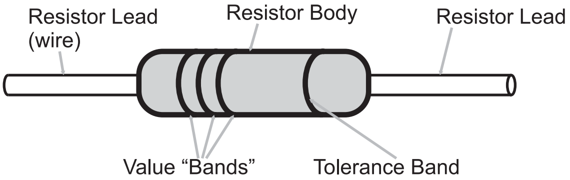

Fig. 3-3. Basic resistor.

measured in ‘‘ohms’’, to electricity. The ‘‘schematic symbol’’ is the jagged line you will see in various schematic diagrams in this book and in other sources. The schematic symbol is the graphic representation of the component and can be used along with the graphic symbol for a gate in a schematic diagram.

In traditional resistors, the amount of resistance is specified by a number of colored bands that are painted on its sides – the values specified by these bands are calculated using the formula below and the values for each of the colors listed in Table 3-2.

$$\texttt{Resistance} = ((\texttt{Band 1 Color Value} \times 10) + (\texttt{Band 2 Color Value})) \times 10^{\texttt{Band 3 Color Value}} \texttt{Ohms}$$

In the introduction to the chapter, I stated that power supplies provide electrons with a specific ‘‘pressure’’ called voltage. Knowing the voltage applied

Table 3-2 Resistor color code values.

Color	Band color value	Tolerance
Black	0	N/A
Brown	1	1%
Red	2	2%
Orange	3	N/A
Yellow	4	N/A
Green	5	0.5%
Blue	6	0.25%
Violet	7	0.1%
Gray	8	0.05%
White	9	N/A
Gold	N/A	5%
Silver	N/A	10%

to a load (or resistor), you can calculate the electrical current using Ohm's law which states:

> The voltage applied to a load is equal to the product of its resistance and the current passing through it.

This can be expressed mathematically as:

$$V = i \times R$$

where "V" is voltage, "R" is resistance and "i" is current. The letter "i" is used to represent current instead of the more obvious "C" because this character was already for specifying capacitance, as I will explain below. Voltage is measured in "volts", resistance in "ohms" and current in "amperes". For the work done in this book, you can assume that ohms have the units of volts/amperes and is given the symbol Ω; you can look up how these values are derived, but for now just take them for what I've presented here. With a bit of basic algebra, once you know two of the values used in Ohm's law, you can calculate the third.

Voltage, current, resistance, and, indeed, all the electrical values that you will see are part of the "SI" (Système Internationale), and its values are governed by SI standards. Each time a unit deviates by three orders of magnitude from the base value, the units are given a prefix that indicates the magnitude multiplier and these multipliers are listed in Table 3-3. For example, one thousandth of a volt is known as a "millivolt". The actual component values are normally given a single letter symbol that indicates its value. Most electronic devices, like resistors are given a two digit value that is multiplied by the power of ten which the symbol indicates. For example,

Table 3-3 Système Internationale magnitude of prefixes and symbols.

Power multiplier	**Prefix**	**Symbol**	**Power multiplier**	**Prefix**	**Symbol**
10^3	kilo	k	10^{-3}	milli	m
10^6	mega	M	10^{-6}	micro	μ
10^9	Giga	G	10^{-9}	nano	n

Resistor 2
Voltage "Drop" Across Resistor 2

Fig. 3-4. Electrical circuit with two resistors in series.

thousands of units are given the prefix "k", so a resistor having a value of 10,000 ohms is usually referred to as having a value of "10 kohms", or most popularly "10 k".

Looking at more complex circuits, such as the two resistor "series" circuit shown in Fig. 3-4, you must remember that individual measurements must be taken across each resistor's two terminals; you do *NOT* make measurements relative to a common point. The reason for making this statement is to point out that the voltage across a resistor, which is also known as the "voltage drop", is dependent on the current flowing through it.

Using this knowledge, you can understand how electricity flows through the two series resistors in Fig. 3-4. The voltage applied to the circuit causes current to flow through both of the resistors and the amount of current is equal to the current passing through a single resistor value which is the sum of the two resistors. Knowing this current, and an individual resistor's value, you can calculate the voltage drop across each one. If you do the calculations, you will discover that the voltage drop across each resistor is equal to the applied voltage.

This may be a bit hard to understand, but go back to the pipe/tap/hose example and think about the situation where you had a pipe/tape/pipe/tap/hose. In this case, there would be a pressure drop across the first tap and then another pressure drop across the second tap. This is exactly what happens in Fig. 3-4: some voltage "drops" across Resistor 1 and the rest drops across Resistor 2. The amount of the drop across each resistor is proportional to its value relative to the total resistance in the circuit.

To demonstrate this, consider the case where Resistor 1 in Fig. 3-4 is 5 ohms and Resistor 2 is 8 ohms. Current has to flow through Resistor 1 followed by Resistor 2, which means that the total resistance it experiences is equivalent to the sum of the two resistances (13 ohms). The current through the two resistors could be calculated using Ohm's law, as voltage applied divided by Resistor 1 plus Resistor 2. The general formula for calculating equivalent the resistance of a series circuit is the sum of the resistances, which is written out as:

$$R_e = R_1 + R_2 + \ldots$$

Knowing the resistor values, the voltage drop across each resistor can be calculated as its fraction of the total resistance; the voltage across Resistor 1 would be 5/13ths of the applied voltage while the voltage across Resistor 2 would be 8/13ths of the applied voltage. Dividing the resistor values into the individual resistor voltage drops will yield the same current as dividing the applied voltage by the total resistance of the circuit.

Adding the two resistor voltage drops together, you will see that they total the applied voltage. This is a useful test to remember when you are checking your calculations, to make sure they are correct.

The properties of series resistance circuits are summed up quite well as Kirchoff's voltage law, which states that "the sum of the voltage drops in a series circuit is equivalent to the applied voltage and current is the same at all points in the circuit."

Along with being able to calculate the amount of current passing through a series resistor circuit and the voltage drop across each resistor, you can also calculate the voltage across each resistor in a parallel resistor circuit like Fig. 3-5 as well as the current through all the resistors. To do this, you have to remember Kirchoff's current law, which states that "the sum of the currents through each resistance is equivalent to the total current drawn by the circuit and the voltage drops across each resistor is the same as the applied voltage."

With each resistor in parallel, it should be fairly obvious that the voltage drop across each one is the same as the applied voltage, and the current flowing through each one can be calculated using Ohm's law. It should also

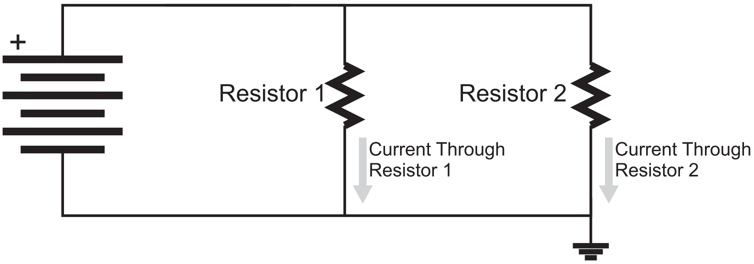

Fig. 3-5. Electrical circuit with two resistors in parallel.

be obvious that the current drawn from the power source is equivalent to the sum of the currents passing through each resistor.

If you were to calculate some different current values for different resistances, you would discover that the general formula for the equivalent resistance was:

$$R_e = 1/(1/R_1) + (1/R_2 + \ldots)$$

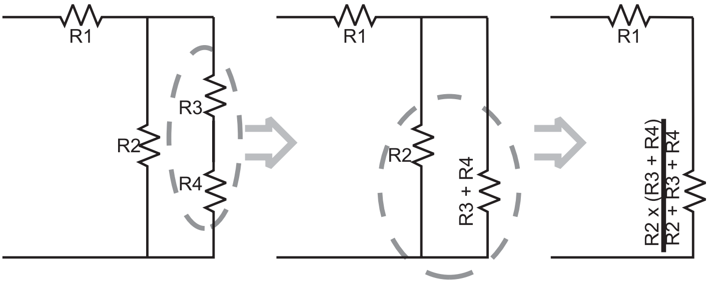
For the simple case of two resistors in parallel, the equivalent resistance can be expressed using the formula:

$$R_e = (R_1 \times R_2)/(R_1 + R_2)$$

Complex resistor circuits, made up of resistors wired in both series and parallel, like the one shown in Fig. 3-6, can be simplified to a single equivalent resistor by applying the series and resistor formulas that I have presented so far in this section. When doing this, I recommend first finding the equivalent to the series resistances and then the equivalent to the parallel resistances until you are left with one single equivalent resistance.

The last piece of basic electrical theory that I would like to leave you with is how to calculate the power dissipated by a resistor. When you took Newtonian physics, you were told that power was the product of the rate at which something was moving and the force applied to it. In electrical circuits, we have both these quantities, voltage being the force applied to the electrons and current being the rate of movement. To find the power being dissipated (in watts), you can use the simple formula:

$$P = V \times i$$



Step 1.
Combine Series
Resistances into a
Single Equivalent
Resistor

Step 2.
Combine Parallel
Resistances into a
Single Equivalent
Resistor

Repeat Step 1 and Step 2
until there is a Single
Resistance Equivalent
to the Resistance of the
"Network"

Fig. 3-6. Reducing the multiple resistor "network" into a single equivalent resistor.

or, if you don't know one of the two input quantities, you can apply Ohm's law and the formula becomes:

$$
\begin{aligned}
P &= V^2/R \\
&= i^2 \times R
\end{aligned}
$$

I must point out that when you are working with digital electronics, most currents in the circuits are measured somewhere between 100 μA to 20 mA. This seemingly small amount of current minimizes the amount of power that is dissipated (or used) in the digital electronic circuits. I'm pointing this out because if you were to get a book on basic electronics you would discover that the examples and questions will usually involve full amperes of current – not thousands or tens of thousands as I have noted here. The reason why basic electronics books work with full amps is because it is easier for students to do the calculations and they don't have to worry about working with different orders of magnitude.

So far in these few initial pages of this chapter, I have gone through the same amount of material that is presented in multiple courses in electrical theory. Much of the background material has been left out as well as derivations of the various formulas. For the purposes of working with digital electronics, you should be familiar with the following concepts:

1. Electricity flows like water in a closed circuit.
2. The amount of current flow in a circuit is proportional to the amount of resistance it encounters.
3. Voltage across a load or resistance is measured at its two terminals.
4. Voltage is current times resistance (Ohm's law).
5. Power is simply voltage times current in a DC circuit.

The other rules are derivations of these basic concepts and while I don't recommend trying to work them out in an exam, what you do remember can be checked against the basic concepts listed above.

Capacitors

When working with digital electronic circuits, it is very important for you to understand the purpose and operation of the capacitor. Many people shy away from working at understanding the role of capacitors in digital electronics because the formulas that define their response to an applied voltage do not seem to be intuitive and many of them are quite complex. Further reducing the attractiveness of understanding capacitors is that they do not seem to be a basic component of digital electronics, and when they are used their value and wiring seems to be simply specified by a datasheet or an application note. I must confess that these criteria used to apply to me and I never understood the importance of capacitors in digital electronics until I was reviewing failure analysis of a 4 MB memory chip. As I will show, a dynamic RAM memory element (along with a MOSFET transistor) is essentially a capacitor, and the failure analysis of the chips showed how the differences in these capacitors affected their operation. One of the major conclusions of the failure analysis was that the memory chip wasn't so much a digital electronic device as a massive array of four million capacitors. This example is meant to show the importance of understanding the operation of capacitors and how they influence digital electronic circuits – being comfortable with the information in this section is more than good enough to use and successfully specify capacitors in digital electronic circuits.

The capacitor itself is a very simple energy storage device; two metal plates (as shown in the leftmost capacitor symbol in Fig. 3-7) are physically separated by a "dielectric" which prevents current from flowing between them. The dielectric is an insulator ("dielectric" is a synonym for "insulator") material which enhances the metal plates' ability to store an electric charge.

The capacitor is specified by the amount of charge it is able to store. The amount of charge stored in a capacitor (which has the symbol "C") is measured in "farads" which are "coulombs" per volt. One coulomb of electrons is a very large number (roughly 6.2×10^{18}) and you will find that for the most part you will only be working with capacitors that can store a very small fraction of a coulomb of electrons.

Knowing that farads are in the units of coulombs per volt, you can find the amount of charge (which has the symbol "Q") in a capacitor by using the formula:

$$Q = C \times V$$

The fraction of a coulomb that is stored in a capacitor is so small, that the most popularly used capacitors are rated in millionth's ("microfarads" or "µF") or trillionth's ("picofarads" or "pF") of farads. Microfarads are commonly referred to as "mikes" and picofarads are often known by the term "puffs". Using standard materials (such as mica, polyester and ceramics), it is possible to build capacitors of a reasonable size of 1 microfarad (one millionth of a farad) but more exotic materials are required for larger value capacitors. For larger capacitors, the dielectric is often a liquid and the capacitor must be wired according to parameter markings stamped on it, as I have indicated in Fig. 3-8. These are known as "polarized" capacitors and either a "+" marking or a curved plate (as shown in Fig. 3-7) is used to indicate how the capacitor is wired in the schematic. Like other polarized components, the positive connection is called an "anode" and the negative a "cathode". Along with the markings, you should remember that the anode of a polarized two lead component is always longer than the cathode. The different lead lengths allow automated assembly equipment to distinguish between the two leads and determine the component's polarity.

Capacitors have two primary purposes in digital electronic circuits. The first is as a voltage "filter" (Fig. 3-9), reducing "spikes" and other problems on a wire carrying current. This use is similar to the use of a water tower in a city; the water tower is filled due to the pressure of the water being pumped into the community. Water is continually pumped to both houses and the water tower, but in times of high usage (like during the day when people are watering their lawns and washing their cars), water from the tower supplements the pumped water to keep the pressure constant. During the

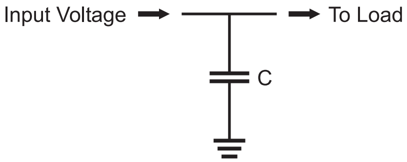

Fig. 3-9. Power supply filter using capacitor.

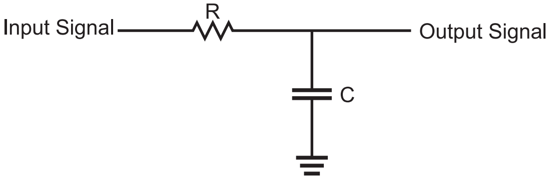

Fig. 3-10. Low-pass filter built from resistor and capacitor.

night, when few people are using water, the pumped water is stored in the water tower, in preparation for the next day's requirements.

When you look at digital electronic circuits, you will see two types of capacitors used for power filtering. At the connectors to the power supply, you will see a high value capacitor (10 µF or more) filtering out any "ripples" or "spikes" from the incoming power. "Decoupling" capacitors of 0.047 µF to 0.1 µF are placed close to the digital electronic chips to eliminate small spikes caused when the gates within the chips change state.

Large capacitors will filter out low-frequency (long-duration) problems on the power line while the small capacitors will filter out high-frequency (short-duration) spikes on the power line. The combination of the two will keep the power line "clean" and constant, regardless of the changes in current demand from the chips in the circuit.

The capacitor's ability to filter signals is based on its ability to accept or lose charge when the voltage across it changes. This capability allows voltage signals to be transformed using nothing more than a resistor and a capacitor, as in the "low-pass filter" shown in Fig. 3-10. This circuit is known as a low-pass filter because it will pass low-frequency alternating current signals more readily than high-frequency alternating current signals.

In digital electronics, we are not so much concerned with how a capacitor affects an alternating current as how it affects a changing direct current. Figure 3-11 shows the response, across Fig. 3-10's low-pass filter's capacitor and resistor, to a digital signal that starts off with a low voltage "steps" up to "V" and then has a falling step back to 0 V.

In Fig. 3-11, I have listed formulas defining the voltage response across the resistor and capacitor to the rising and falling step inputs. These formulas are

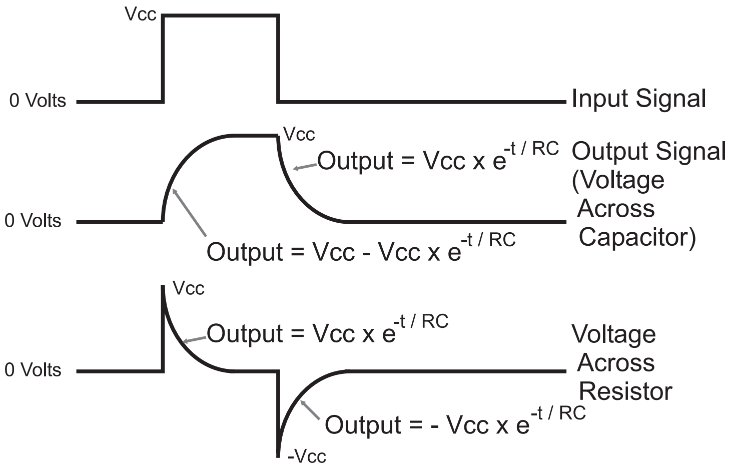

Fig. 3-11. Resistor/capacitor circuit response to changing input.

found within introductory college electricity courses by knowing that the voltage across the capacitor can be defined by using the formula:

$$V_C(t) = Q_C(t)/C$$

which simply states that the voltage across a capacitor at some point in time is a function of the charge within the capacitor at that point of time. The charge within the capacitor is supplied by the current passing through the resistor and the resistor limits the amount of current that can pass through it. As the voltage in the capacitor increases, the voltage across the resistor falls and as the voltage across the resistor falls, the amount of current that is available to charge the capacitor falls. It is a good exercise in calculus to derive these formulas, but understanding how this derivation works is not necessary for working with digital electronics.

There are two things I want to bring out from the discussion of low-pass filters. The first is that the response of the low-pass filter is a function of the product of the resistance and capacitance in the circuit. This product is known as the “RC time constant” and is given the Greek letter “tau” (τ) as its symbol. Looking at the formulas, you should see that by increasing the value of τ (either by using a larger value resistor or capacitor) the response time of the low-pass filter is increased.

This has two ramifications for digital electronics. The first should be obvious: to minimize the time signals take to pass between gates, the resistance and capacitance of the connection should be minimized. The second is more subtle: the resistor–capacitor response can be used to delay a signal in a circuit. This second issue with resistor–capacitor circuits is actually very useful in digital electronics for a number of different applications that I will discuss later in the book.

This is a very short introduction to capacitors and their operation in (digital) electronic circuits. Before going on, I would like to reinforce what I've said about their importance and recommend that you follow up this section's material by working through a book devoted to analog electronics.

Semiconductor Operation

Over the past 100 years, we have refined our ability to control the electrical properties of materials in ways that have made radios, TVs and, of course, digital electronic circuits possible. These materials have the ability to change their conductance, allowing current to pass through them under varying conditions. This ability to change from being an insulator to a conductor has resulted in these materials being called ''semiconductors'', and without them many of the basic devices we take for granted would be impossible.

The most basic electronic semiconductor device is the ''diode''. The electrical symbol and a sketch of the actual part is shown in Fig. 3-12. Diodes are a ''one-way'' switch for electricity; current will pass easily in one direction and not in the other. If you were to cut a silicon diode in half and look at its operation at a molecular level, you would see that one-half of the silicon was ''doped'' (infused with atoms) with an element which can easily give up electrons, which is known as an ''N-type'' semiconductor. On the other side of the diode, the silicon has been doped with an element that can easily accept electrons, a ''P-type'' semiconductor.

Fig. 3-12. Diode symbol.

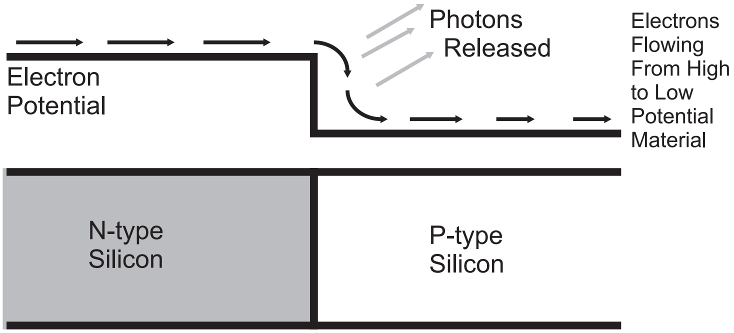

Fig. 3-13. Diode operation.

When a voltage is applied to the diode, causing electrons to travel from the atoms of the N-type semiconductor to the atoms of the P-type, the electrons "fall" in energy from their orbits in the N-type to the accepting orbit spaces in the P-type, as shown in Fig. 3-13. This drop in energy by the electron is accompanied by a release in energy by the atoms in the form of photons. The "quanta" of photon energy released is specific to the materials used in the diode – for silicon diodes, the photons are in the far infrared.

The voltage polarity applied to the diode is known as "bias". When the voltage is applied in the direction the diode conducts in, it is known as "forward biased". As you might expect, when the voltage is applied in the direction the diode blocks current flow, it is known as "reverse biased". This is an important point to remember, both for communicating with others about your designs and for understanding the operation of transistors, as explained below.

To keep the thermodynamic books balanced, the release in energy in terms of photons is accompanied by a corresponding voltage drop across the diode. For silicon diodes, this drop is normally 0.7 volts. The power equation I gave earlier ($P = V \times i$) applies to diodes. When large currents are passed through the diode and this is multiplied by 0.7 V, quite a bit of power can be dissipated within the diode.

If voltage is applied in the opposite direction (i.e. injecting electrons into the P-type side of the diode), the electrons normally do not have enough energy to rise up the slope and leave the orbits of the P-type atoms and enter the electron-filled orbits of the N-type atoms. If enough voltage is applied, the diode will "break down" and electrons will jump up the energy slope. The break down voltage for a typical silicon diode is 100 V or more – it is quite substantial.

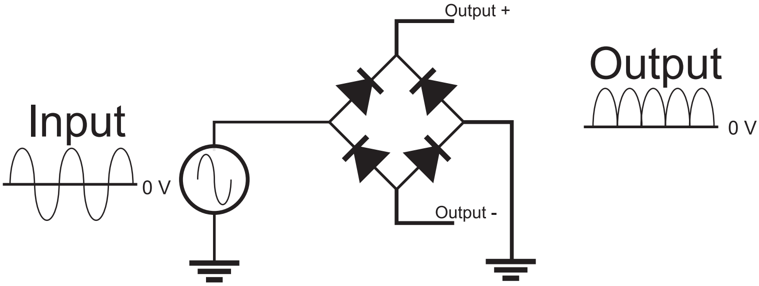

Fig. 3-14. "Full wave rectifier" using four diodes.

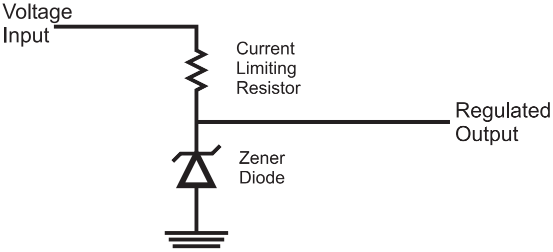

Fig. 3-15. Zener diode voltage regulator.

A typical use for a diode is to "rectify" AC to DC, as shown in Fig. 3-14, in which a positive and negative alternating current is converted using the four diodes to a "lobed" positive voltage signal, which can be filtered using capacitors, as discussed in the previous section.

Along with the simple silicon diode discussed above, there are two other types of diodes that you should be aware of. The first is the "Zener" diode which will break down at a low, predetermined voltage. The typical uses for the Zener diode is for accurate voltage references (Zener diodes are typically built with 1% tolerances) or for low-current power supplies like the one shown in Fig. 3-15. The symbol for the Zener diode is the diode symbol with the bent current bar shown in Fig. 3-15.

Building a power supply using this circuit is actually quite simple: the Zener diode's break down voltage rating will be the "regulated output" and the "voltage input" should be something greater than it. The value of the current limiting resistor is specified by the formula

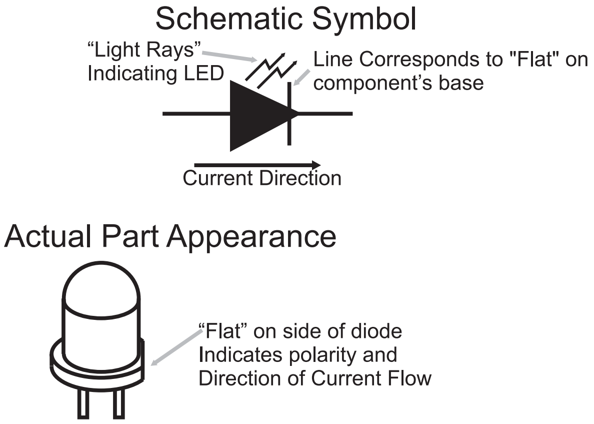
$$\mathtt{R}_{\mathtt{iLimit}} = (\mathtt{V}_{\mathtt{in}} - \mathtt{V}_{\mathtt{Zener}})/\mathtt{i}_{\mathtt{app}}$$

where "i_{app}" is the current expected to be drawn (plus a couple of tens of percent margin). The power rating of the Zener diode should take into account the power dissipated if i_{app} was passing through it.

As I will discuss later in this chapter, there are a lot of inexpensive power regulators that are a lot more efficient than the Zener diode one shown in Fig. 3-15. If you do the math for a typical application (say 9 volts in, 5.1 volt Zener diode and a 20 mA current draw), you will find that at best it is 60% efficient (which is to say 60% of the power drawn by the Zener regulator circuit and the application is passed to the application, and can often be as low as 25%). The reason for using the Zener diode regulator is its low cost, very small form factor and extreme robustness. Most practical applications will use a linear regulator chip.

The other type of diode that I want to mention in this section is one that you are already very familiar with – the light-emitting diode or LED. As its name implies, this diode emits light (like a light bulb) when a current passes through it. In Fig. 3-16, note that the LED symbol is the same as the diode's symbol, but with light rays coming from it. The most common package for the LED is also shown in Fig. 3-16 and it consists of a rounded cylinder (somewhat like "R2D2" from Star Wars) with a raised edge at its base with one side flattened to indicate the LED's cathode (negative voltage connection).

There are a few points that you should be aware of with regard to LEDs. In the past few years, LEDs producing virtually every color of the rainbow (including white) have become available. I must point out that LEDs can only produce one color because of the chemistry of the semiconductors used to build them. You may see advertisements for two or three color LEDs, but these devices consist of two or three LEDs placed in the same plastic package and wired so that when current passes through its pins in a certain direction, a specific LED turns on.



Schematic Symbol
"Light Rays" Indicating LED
Line Corresponds to "Flat" on component's base
Current Direction
Actual Part Appearance
"Flat" on side of diode Indicates polarity and Direction of Current Flow

Fig. 3-16. LED symbol.

The brightness of a LED cannot be controlled reliably by varying the current passing through it, as you would with a light bulb. LEDs are designed to provide a set amount of light with current usually in the range of 5 to 10 mA. Reducing the current below 5 mA may dim its output or it may turn it off completely. A much better way to dim a LED is to use "pulse wave modulation" (PWM), in which the current being passed to the LED is turned on, and faster than the human eye can perceive, with varying amounts of on and off time to set the LED's brightness. I will discuss PWMs later in the book.

Finally, when I first introduced diodes, I noted that silicon diodes output photons of light in the far infrared and have a 0.7 volt drop when current passes through them. To produce visible light, LEDs are not made out of silicon, they are made from other semiconductor materials in which the energy drop from the N-type semiconductor to the P-type semiconductor produces light in the visible spectrum. This change in material means that LEDs do not have silicon's 0.7 V drop; instead, they typically have a 2.0 V drop. This is an important point because it will affect the value of the current limiting resistor that you put in series to make sure the LED's current limit rating is not exceeded or that it does not allow too much current in the circuit to pass through it, resulting in an unnecessary current drain.

It is always a source of amazement to me how many people do not understand how transistors work. For the rest of this section, I will introduce you to the two most common types of transistors and explain how they work as well as what applications they are best suited for. Understanding the characteristics of the two types of transistors is critical to understanding how digital logic is implemented and how you can interface it to different technologies.

As I explain the operation of the "bipolar" transistor, I will endeavor to keep to the "high level" and avoid trying to explain transistor operation using tools like the "small signal model", which is intimidating and obfuscates the actual operation of the device. Instead, I want to introduce you straight to the "NPN bipolar transistor" by its symbol and typical package and pinout for a small scale (low-power) device in Fig. 3-17.

As you have probably heard, a bipolar transistor can be considered a simple switch or a voltage amplifier, but you are probably mistaken on how it is controlled and how it actually works. The transistor is not voltage controlled (as you may have been led to expect); it is actually current controlled. The amount of current passing through the "base" to the "emitter" controls the amount of current that can pass from the "collector" to the emitter. The amount of current that can be passed through the collector is a multiple (called "beta" and given the symbol "β" or h_{FE}) of the

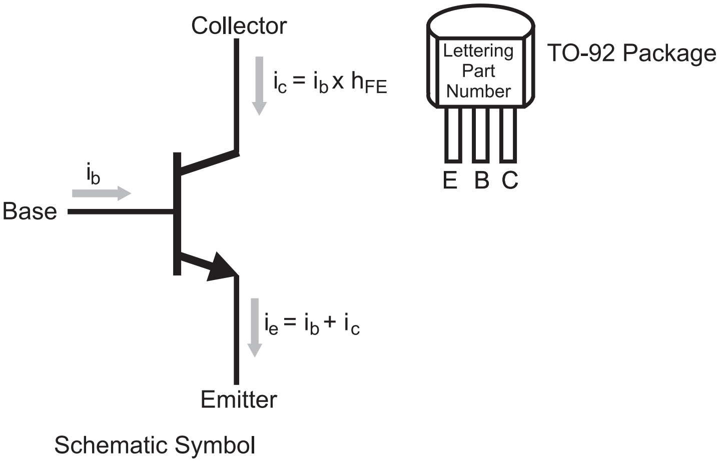


Fig. 3-17. NPN transistor symbol with parameters.

current flowing through the base; the bipolar transistor is actually an amplifier – a small amount of current allows a greater amount to flow. The simple formulas for the relationship between the base and collector currents are listed in Fig. 3-17.

I must point out that these formulas apply while the maximum collector current is in the ‘‘small signal’’ or ‘‘linear’’ operating range. As a physical device, a transistor can only allow so much current to flow through it; as it reaches this limit, increases in the transistor’s base current will not result in a proportional increase in collector current. This operating region is known as the ‘‘non-linear’’ or ‘‘saturation’’ region and what happens in this situation can be easily understood by looking at what happens in a cross section of a transistor (Fig. 3-18).

A bipolar transistor consists of a P-type semiconductor sandwiched between two N-type semiconductors. This structure forms a reverse biased diode and no current can flow through it. With no current being injected into the NPN bipolar transistor, the P-type semiconductor is known as the ‘‘depletion region’’ because it does not have any electrons. When current is passed to the device, electrons are drawn through the P-type semiconductor via the emitter N-type semiconductor. As electrons are drawn into the P-type semiconductor, the properties of the P-type semiconductor change and take on the characteristics of the N-type semiconductors surrounding it and becomes known as the ‘‘conduction region’’. The more electrons that are drawn from the P-type semiconductor, the larger the conduction region bridging the two pieces of N-type semiconductor and the greater amount of current that can pass from the collector to the emitter. As more electrons are

drawn from the P-type semiconductor, the conduction region grows until the entire P-type semiconductor of the transistor becomes "saturated".

The PNP bipolar transistor (Fig. 3-19) operates in the complete opposite way to the NPN transistor. It is built from an N-type semiconductor between two P-type semiconductors and to create a conduction region, electrons are injected into the base instead of being withdrawn, as in the case of the NPN bipolar transistor. As in the NPN bipolar transistor, the amount of collector current is a multiple of the base current (and that multiple is also called β or h_{FE}).

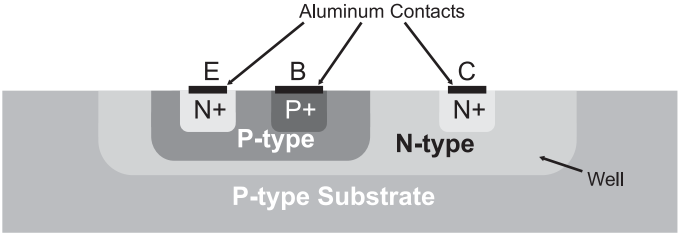

Fig. 3-20. Side view cross section of NPN bipolar transistor in an integrated circuit.

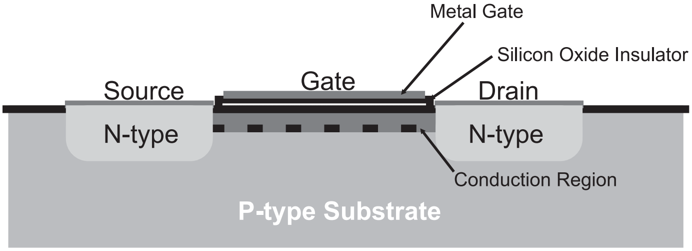

Fig. 3-21. N-channel MOSFET side view showing features during operation.

Bipolar transistor h_{FE} values can range anywhere from 50 to 500 and the amount of collector current they can handle ranges from a few tens of milliamps to tens of amps. As well as discrete (single) devices being inexpensive, they respond to changes in inputs in extremely short time intervals. You may think they are perfect for use in digital electronics, but they have two faults that make them less than desirable. First, the base current is actually a source of power dissipation in the device, which is usually not an issue when single transistors are used, but is of major concern when thousands or millions are used together in a highly complex digital electronic system.

Secondly, they take up a lot of chip "real estate" and are very expensive to manufacture. Figure 3.20 shows the side view of an NPN bipolar transistor built on a silicon chip. Instead of butting together different types of semiconductor, it is manufactured as a series of "wells", which are doped with the chemicals to produce the desired type of semiconductor by repeated operations. As many as 35 process steps are required to produce a bipolar transistor.

The N-channel enhancement "metal oxide silicon field effect transistor" (MOSFET) does not have these faults – it is built using a much simpler process (the side view of the transistor is shown in Fig. 3-21) that only requires one doping of the base silicon along with the same bonding of aluminum contacts as the bipolar transistor. N-channel MOSFETs (as they are most popularly known) require nine manufacturing processes and take a fraction of the chip real estate used by bipolar transistors.

The N-channel MOSFET is not a current-controlled device, like the bipolar transistor, but a voltage-controlled one. To ‘‘turn on’’ the MOSFET (allow current to flow from the ‘‘source’’ to the ‘‘drain’’ pins), a voltage is applied to the ‘‘gate’’. The gate is a metal plate separated from the P-type silicon semiconductor substrate by a layer of silicon dioxide (most popularly known as ‘‘glass’’). When there is no voltage applied to the gate, the P-type silicon substrate forms a reverse biased diode and does not allow current flow from the source to the drain. When a positive voltage is applied to the gate of the N-channel MOSFET, electrons are drawn to the substrate immediately beneath it, forming a temporary N-type semiconductor ‘‘conduction region’’, which provides a low-resistance path from the source to the drain. MOSFET transistors are normally characterized by the amount of current that can pass from the source to the drain along with the resistance of the source/drain current path.

The symbol for the N-channel MOSFET, along with its complementary device, the P-channel MOSFET are shown in Fig. 3-22. The P-channel MOSFET creates a conduction region when a negative voltage is applied to its gate. MOSFET transistors come in a variety of packages and some can handle tens of amps of current, but they tend to be very expensive.

MOSFETs do not have the issues of bipolar transistors; their gate widths (the measurement used to characterize the size of MOSFET devices) are, at the time of this writing, as small as 57 nm in high-performance microprocessors and memory chips. The voltage-controlled operation of MOSFETs eliminates the wasted current and power of the bipolar transistor’s base, but while MOSFETs do not have the disadvantages of bipolar transistors, they do not have their advantages.

MOSFET transistors do not have a small signal/linear operating region; they tend to change from completely off to completely on (conducting) with a

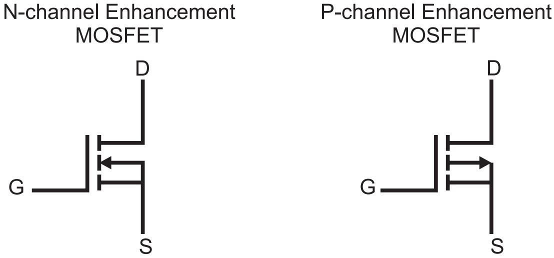

Fig. 3-22. MOSFET schematic symbols.

very small intermediate range. MOSFETs also tend to operate at slower speeds than bipolar devices because the gates become capacitors and "slow down" the signals, as I showed in the previous section. This point has become somewhat moot as modern MOSFET designs are continually increasing in speed, providing us with extremely high-speed PCs and other electronic devices. Finally, it is difficult to manufacture MOSFETs with high current capabilities; while high current MOSFETs are available, they are surprisingly expensive.

The characteristics of the two types of transistors give way to the conclusion that bipolar transistors are best suited to situations where a few high current devices are required. MOSFET transistors are best suited for applications where large numbers of transistors are placed on a single chip.

Today, for the most part, digital electronic designs follow these guidelines, but we are left with an interesting legacy. Despite being much simpler structurally and cheaper to manufacture, MOSFET transistors were only perfected in the late 1960s, whereas bipolar technology had already been around for 20 years and it was able to become entrenched as the basis for many digital electronic devices and chips. For this reason, you must be cognizant of the operating characteristics of bipolar transistors as well as those of MOSFET transistors. In the next section, many of these differences will become apparent.

Logic Gate Input and Output

If you have worked with digital electronics before, you probably have made a few assumptions about how the circuitry works and how you can demonstrate how digital electronic devices work. Chances are many of these assumptions are with regard to how gate and chip inputs and outputs work as well as how to properly interface them together and to different electronic devices. These assumptions are generally made on the evidence of by what somebody has seen with a voltmeter or logic probe and do not look at the underlying circuitry and how it works. In this section, I will give you a detailed introduction to the input and output pins on digital electronics and how they should be wired.

When we talk about digital electronics, we should identify the different technologies used. "Transistor to transistor logic" (TTL) is based on NPN bipolar transistors. TTL chips have the part number prefix "74" (i.e. a chip with four, two input NAND gates known as the "7400"). There are actually quite a few different technology chip families based on the 74xx "standard" pinout and operation and the technology is indicated by letter codes following the "74"; a chip marked with "74LS00" is a low-power, Shotkey four two-input NAND gate chips. Many of these technologies used with the 7400 series of chips are based on bipolar transistors, but some are based on MOSFET technology. These MOSFET technology based chips have the 74 prefix and a technology letter code containing a "C" (i.e. "C", "HC", "HCT"). Along with being used in 7400 series form factors, MOSFET devices are used in the "4000" series of logic chips. Understanding which type of transistor is used in a logic chip is critical to being able to successfully interface it to other chips or input/output devices.

When the term "TTL" is used, it is referring to bipolar transistor logic in the 7400 series. "CMOS" indicates MOSFET transistor logic used in the 74C00 and 4000 chip logic series.

Probably the biggest erroneous assumption that people have about digital logic is that TTL circuitry is voltage controlled. In the previous section, I emphasized the notion that bipolar transistors are *current* controlled and not voltage controlled. I'm sure that many people will argue with me and say that when they put a voltage meter to the input of a TTL gate, they saw a high voltage when a "1" was being input and a low voltage when a "0" was input. I won't argue with what they have seen; although I will state that the conclusion that TTL logic is voltage controlled made from these observations is incorrect.

The standard TTL input consists of an NPN bipolar transistor wired in the unusual configuration shown in Fig. 3-23. On the left side of this diagram, I have drawn a two input TTL gate which is implemented with a two emitter

No Current to TTL Gate
Current Path Through Input Pins, Keeping Current from Gate Logic

Fig. 3-24. Current control operation of TTL inputs.

NPN transistor – as unusual as this type of transistor sounds, they really do exist. To understand how the input works, I replaced the two emitter NPN transistor with the three diode equivalent "model" on the right side of Fig. 3-23.

Normally, an NPN transistor passes current from its base to the emitter, but when wired in the TTL input configuration, the base current does not have a path through the transistor's emitters and passes through the transistor's collector to the gate logic. Figure 3.24 shows this situation along the other case where one of the input transistor's emitter's is tied to ground and the base current passes through the emitter and not the collector. The logic connected to the input NPN transistor's collector responds depending on whether or not current is available from the collector.

Obviously a simple switch, connected to ground, will allow current to pass through the emitter but you are probably wondering how other logic devices can control this device. A typical logic device output looks like Fig. 3-25 and consists of two transistors: one that will connect the output to the device power and one that will connect the output to the device ground. This transistor path to ground will provide the emitter current path of the chip. When the output is a high voltage (the top transistor is on and the bottom one is off), no current will flow into the TTL input gate because of the reverse diode nature of the emitter input pin.

The TTL output shown in Fig. 3-25 is known as a "totem pole" output because of its resemblance to its namesake. If you were to connect a totem pole output to a TTL input and measured the voltage at the input or output pins, you would see a high voltage, which the gate connected to the input

Output Control Current
Output Pin, NPN Transistor Can ONLY Pull Pin to Ground

Fig. 3-26. TTL open collector output.

would respond to as a "1". When a low voltage is output, the TTL gate will respond as if a "0" was input. What you are not measuring is the current flow between the two pins.

There are two terms used in Fig. 3-25 that I should explain. When a transistor is connected to the power supply of a chip and is turned on, it is said to be "sourcing" current. When a transistor is connected to ground and is turned on, the transistor is said to be a current "sink". I will use these terms throughout the book and you will see in other books and references any time a device is either supplying ("sourcing") or taking away ("sinking") current.

There is another type of output which does not source any current and is known as the open collector output (Fig. 3-26). This output typically has two uses. The first is it can pull down voltages which are greater than the positive voltage applied to the chip. Normally these voltages are less than 15 V and can only source 10 to 20 mA. For higher currents and voltages, discrete transistors must be used.

By not sourcing any current, these outputs can be "ganged" together in parallel, as I have shown in Fig. 3-27. This circuit is known as a "dotted AND" because it only outputs a 1 if all the outputs are "high" and each

Fig. 3-27. Multiple ‘‘open collector’’ outputs combined to form a ‘‘dotted AND’’ gate.

transistor is ‘‘off’’ and not pulling the common output line to ground. Note that there must be a pull up resistor connected to the output to provide a high-voltage, low-current source. Dotted AND gates are useful in a variety of different situations ranging from circuits where an arbitrary number of outputs can control one line or where digital outputs and buttons are combined. (I will discuss this in more detail later in the book.)

Totem pole outputs are the recommended default gate output because you can easily check voltage levels between intermediate gates in a logic string. As I will show later in this chapter, you cannot use a voltmeter or logic probe to check the logic levels if a TTL gate is driven by an open collector output. Along with this, a CMOS input is connected to an open collector (or open drain, as I will discuss below) output. Then there will be no high voltage for the gate to operate. The only cases where an open collector/open drain output should be used is when you are wiring a dotted AND gate or are switching an input that is operating at a voltage different from the gate's power.

TTL output pins are internally limited to only sink or source around 20 mA of current, which limits the number of inputs that it can drive. If you were to do the math, you would discover that when a TTL input is pulled low, 1.075 mA of current is passed through the output pin (this was found by assuming the base/emitter voltage of a transistor is 0.7 volts and the current limiting resistor connected to the input transistor's base is 4 k, which is typical for TTL inputs.

Along with the totem pole and the open collector outputs, there is also the "tri-state driver" output, which cannot only source or sink current but can be turned "off" to electrically isolate itself from the circuit that it is connected to. I will discuss tri-state drivers later in the book, when I present busses and multiple devices on the same line.

Knowing that each TTL input requires a current sink of just over 1 mA and most TTL outputs can sink up 20 mA, you might expect the maximum number of TTL inputs driven by a single output (which is called "fanout") to be 18 or 19. The actual maximum fanout is 8 to ensure that there is a comfortable margin in the output to be able to pull down each output in a timely manner. Practically, I would recommend that you try to keep the number of inputs driven by an output to two and never exceed four. Some different technologies that you work with, do not have the same electrical drive characteristics and may not be designed to pull down eight inputs of another technology; so, to be on the safe side, always be very conservative with the number of inputs you drive with a single output.

Re-reading the last sentence of the previous paragraph, you might wonder if any potential low-drive situations could be improved by wiring multiple outputs together. This must be avoided because of the danger that the gates will switch at different times, resulting in large currents passing through the gate output circuitry, and not through the net the outputs are connected to.

The CMOS logic gate input (Fig. 3-28) is quite a bit simpler than the TTL gate input and much easier to understand. The CMOS input and, as I will explain, the output, consist of a balanced P-channel MOSFET and an N-channel MOSFET wired as a very high gain amplifier. The slightest positive or negative voltage applied to this input circuit will cause the

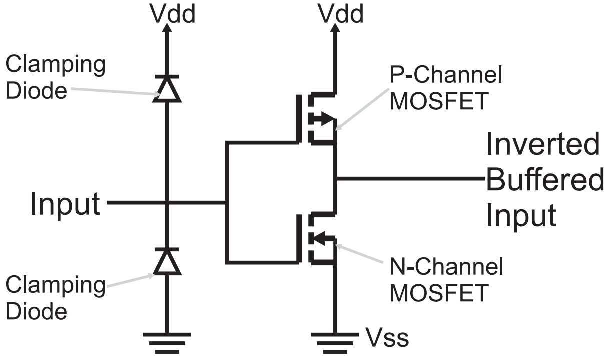

Fig. 3-28. Basic CMOS input/output circuit.

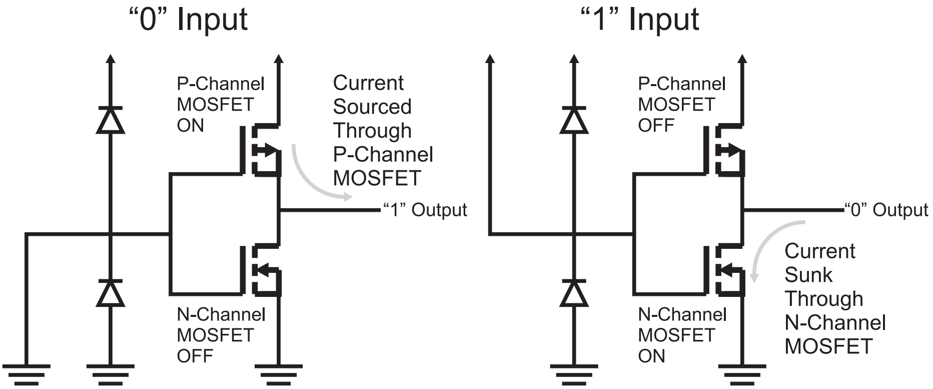

Fig. 3-29. CMOS gate response for different inputs.

appropriate transistor to turn on and either source current (in the case where a negative voltage is applied and the P-channel MOSFET turns on) or sink current (a positive voltage will turn on the N-channel MOSFET). This operation can be seen in Fig. 3-29.

One interesting aspect of the two MOSFET transistors that I have shown wired as an inverter is that they not only provide the ability to sense and respond to voltage inputs, but as the voltage controls transistor switches, they are also effective totem pole output circuits as well. Not only are MOSFET transistors much easier to place on a piece of silicon semiconductor and can be placed in a smaller amount of surface area but also gates built from them are also much simpler than their TTL counterparts.

When the P-channel MOSFET is removed from the output of a CMOS gate, its output is said to be ‘‘open drain’’. This term refers to the drain of the N-channel MOSFET that is not connected to a transistor which can source current in just the same way as an ‘‘open collector’’ TTL output transistor and does not have a transistor which can source current. The CMOS logic open drain output works exactly the same way as the TTL open collector output.

The two ‘‘clamping diodes’’ are placed in the circuit to hold the voltages to within Vdd (power input) and Vss (ground) and are primarily there to protect the P-channel and N-channel MOSFETs from damage from static electricity. These diodes also provide you with the ability to power a CMOS chip through its input pins; when no voltage is applied to Vdd but there is a high-voltage input to one or more input pins, the clamping diodes will allow current to pass to the internal MOSFETs and power the circuit. This is usually an undesirable side effect and one that you should watch for.

The clamping diode function is provided in TTL by the diode and the bipolar transistor emitter that makes up a TTL gate input. Whereas CMOS logic requires additional diodes built into the circuitry, TTL has this function built in.

Unlike TTL, CMOS logic is voltage controlled; there is no path for current to enter or leave the MOSFET's gate circuitry. This has some interesting side effects that you should be aware of. The first is that while at first glance of the inverter operation in Fig. 3-29 it appears that there is no current flow if the output of the CMOS input transistors was another CMOS gate, there actually is a very small amount of change passed to the gates of the transistor from Vdd when the P-channel MOSFET is turned on and this charge is sunk to Vss when the N-channel MOSFET is turned on. This transfer of charge grows with the number of CMOS gates as well as the speed that the gates switch; the faster they switch the more charge that is transferred over time. As I discussed at the start of this chapter, the measurement of charge movement over time is current.

Earlier in the book, I said that the basic gate used in CMOS logic circuits is the NOR gate (just as the NAND gate is the basic gate used in TTL). Before leaving this chapter, I would like to show you the circuit used by a CMOS NOR gate (Fig. 3-30). If you trace through the operation of the four MOSFETs that make up this circuit, you will discover that the only time both P-channel MOSFETs are on (and voltage/current from Vdd is passed to the "Output") is when the two inputs are low, which matches the expected operation of the NOR gate.

The reason why the NOR gate was selected for use as the basic CMOS logic gate has to do with how MOSFETs and other circuits are put

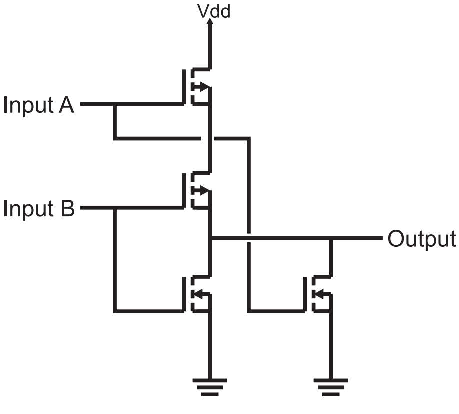

Fig. 3-30. CMOS NOR gate.

down on a silicon semiconductor. The NOR gate is the most efficient while the NAND (which would make the basic building blocks of TTL and CMOS logic the same) cannot be accomplished as easily and in as small amount of space.

The last point I want to make about inputs and outputs is how to wire them when you want to hold them at a specific state (high/"1" or low/"0"). While you could connect the pins directly to power (for a high input) and ground (for a low input), I want to show you the recommended way of doing this and explain why you should go through the extra effort. Connecting the input to high value is accomplished using a 10 k resistor (called a "pull up"), as I show in Fig. 3-31. This circuit will allow input to be temporarily wired to ground (for testing or circuit debug), without causing a short circuit (a low-resistance path between positive and negative power voltage).

Providing a "pull down" (connection to ground) is not quite so simple; the single resistor pull up of Fig. 3-31 is input into an inverter, as shown in Fig. 3-32. This circuit allows the pull up to be connected to ground for testing and debug (changing the input of the gate to a high from a solid low) just as in the pull up case.

Fig. 3-32. Recommended way to "pull down" a logic input.

If you have followed the gate explanations up to this point, you might be feeling like these methods of tying the gates to pull ups and pull downs is "overkill". I admit that these methods may seem more complex than just wiring the inputs to positive or negative power, but there are a number of reasons for specifying that pull ups and pull downs are wired in this way. For TTL, to make an input high all the time it can be simply left unconnected and to pull it down it can be pulled directly to ground; the 1 mA of current that will flow through the gate to ground should not be an excessive amount of current. For CMOS logic, the input pin can be tied directly to Vdd (positive power) for a high input and Vss (negative power) for a low input – there will be no current flow in either case. It is important to understand the three reasons why I recommend using the pull up resistor or the pull up resistor and inverter.

First, as I said above, it allows you to temporarily change the input value by connecting the resistor voltage to negative voltage without worrying about damaging any part of the circuit. Secondly, it allows simple test equipment to change the state of the input pin for testing without potentially overloading the circuit or the tester. This is a very important consideration when you are designing a product for mass production. Finally, this method can be used for both TTL and CMOS logic without regard to what type of logic is being used. I realize that going through the rigor of following these recommendations increases the complexity of a circuit as well as increasing the number of gates required, its cost and power consumption. In many cases, you will not feel that it is necessary, but if you decide to forgo using pull ups and inverted pull ups, make sure you understand what are the tradeoffs and the risks of the decision.

Simple Digital Logic Circuit Development

Many people do not realize that it is quite easy to build sample digital electronic logic circuits that demonstrate the concepts that have been presented to you as well as let you try out your own simple experiments. If you have, or are taking, a course in digital electronics, it probably includes a well-equipped laboratory in which you worked through a number of experiments. You do not need to replicate this laboratory at home if you wish to experiment with digital electronics. As I will show in this chapter, you can come up with a very capable digital logic circuit test kit for less than $20 and use parts available in modest electronics stores (like "Radio Shack").

Chances are, you are familiar with a variety of different electrical power sources: the ones that comes to mind first are batteries. There are a confusing number of different batteries that you can choose from, ranging from simple ‘‘AA’’ batteries that cost a few cents to the batteries used in the International Space Station that weigh (on Earth) 1200 pounds and cost over $200,000 each. Along with batteries, electricity can also be produced by generators, solar cells and fuel cells. Within your home you can access electrical power very conveniently through outlets in the walls, although this power is *alternating current* (‘‘AC’’) and not the *direct current* (‘‘DC’’) required for digital logic. AC power coming from the sockets in your home will have to be reduced and rectified into DC.

When you are experimenting with simple electronics, I think it’s best to use a power source that is definitely ‘‘low end’’; ‘‘alkaline’’ and rechargeable nickel–metal hydride (‘‘NiMH’’) batteries are widely available to power your experiments. TTL digital electronic chips generally operate between 4.5 and 5.5 volts – you could come up with a combination of batteries that will provide 5 volts to your circuit, or convert a 9 volt radio battery output to 5 volts using a ‘‘regulator’’. Rather than going through this effort and potential expense for TTL, I am going to recommend that you use CMOS digital logic chips that can be powered by 9 volts directly.

A 9 volt battery ‘‘clip’’ (Fig. 3-33) will cost you just a few cents and a bag of them can be bought for a dollar or so. For the purposes of the digital logic circuit test kit, you should look for a 9 volt battery clip that either has wire’s individual strands soldered together (the ends of the wires will look silver, shiny and attached together) or has a single strand. The wires will be covered

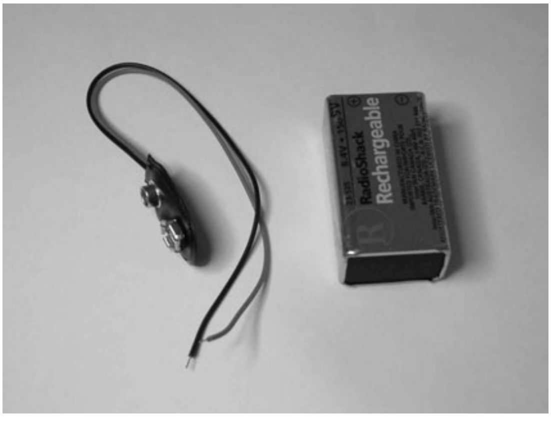

Fig. 3-33. 9 volt battery clip with red (positive) and black (negative) wires attached to it.

in a red and black plastic insulation and the strands will poke out the ends for a 1/4 inch or so.

Make sure the strands of the 9 volt battery clip wires are either soldered together or the wires consist of a single strand, because the wires from the battery clip will be pushed into holes and clamped by copper springs to provide power for the test circuits. Loose, individual strands break easily, can short with other loose wires or become a tangled mess, none of which are good things.

The battery clip is only one part of the wiring that will be used with the digital logic circuit test kit. By itself, the battery clip brings power out of the 9 volt battery conveniently, but is difficult to work with when you are working with chips and even moderately complex circuitry. The ‘‘breadboard’’ and wiring kit (Fig. 3-34) provide a customizable platform in which chips and other electronic components can be inserted into and easily wired together.

‘‘Breadboards’’ allow you to simply and quickly wire up your own prototyping circuits. From the top, a breadboard looks like a sea of holes, but if you were to ‘‘peel back’’ the top (Fig. 3-35), you would see that the holes are actually interconnected, with the central groups of holes connected outwards and the outermost two sets of holes connected along the length of the breadboard.

The central holes are spaced so that DIP chips can be placed in the breadboard and wired into the circuit easily. The outside two rows

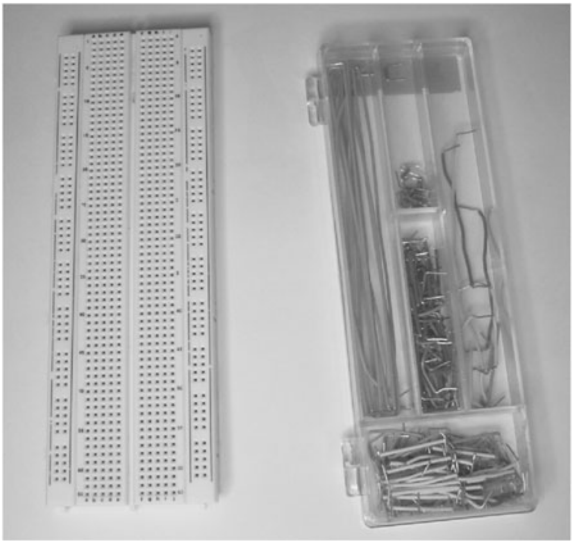

Fig. 3-34. Breadboard with a wiring kit.

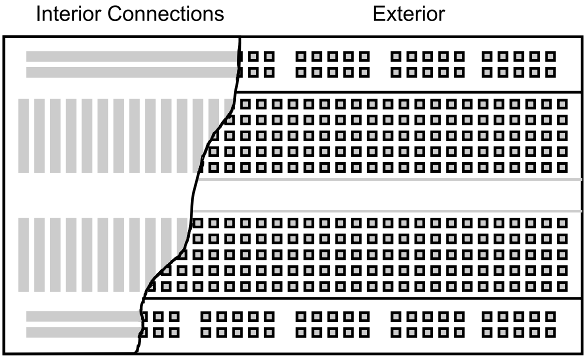

Fig. 3-35. “Breadboard” with interior connections shown.

of holes, I use as power “buss bars” and connect the power source to them directly.

Along with the breadboard, you can either buy a pre-cut and stripped wiring kit (shown in Fig. 3-34) or a roll of 24-gauge solid core wire and some needle nose pliers, wire clippers and maybe some wire strippers. For convenience, I usually go with the wiring kit as it costs just a few dollars.

Along with buying the battery clip, breadboard and wiring kit, you should also buy:

1. 5 or so LEDs in a 5 mm package
2. 10 or so 1k, 1/4 watt resistors
3. 10 or so 0.01 µF ceramic capacitors
4. One 555 oscillator/monostable chip
5. 5 or so SPDT switches, that can be inserted into the breadboard
6. One 74C00 quad two-input NAND gates chips
7. One 74C02 quad two-input NOR gates chips
8. One 74C04 hex inverter chip
9. One 74C08 quad two-input AND gates chip
10. One 74C32 quad two-input OR gates chip
11. One 74C74 dual D-flip flop chip.

All these parts should cost you less than $20 and are available at a fairly wide variety of sources including:

- Radio Shack (http://www.radioshack.com)
- Digi-Key (http://www.digikey.com)
- Mouser Electronics (http://www.mouser.com)
- Active Components (http://www.active-electronics.com).

You will not require any test equipment (such as a Digital Multi-Meter) for this kit and the sample circuits that I will present in this book.

Testing a Simple TTL Inverter

So far I have used the term ‘‘load’’ when I’ve described the electronic devices that are to be used in a circuit, but before going on, I want to familiarize you with the basic, ‘‘dual in-line package’’ ‘‘chip’’ (Fig. 3-36). The ‘‘chip’’ consists of a rectangular plastic box which has a series of metal pins (or connections) coming out from the two long sides. These pins are the electrical connections that are to be made to make up the digital logic circuits as well as provide power to the chip. As I have shown in Fig. 3-36, there can be one or two ‘‘pin 1’’ indicators on each chip (not all chips have both indicators) and the pins are numbered by going counterclockwise around the top of the chip.

Before leaving this chapter, I would like to show both how easy it is to create a simple circuit to test out ideas and parts of applications as well as demonstrate how the TTL gate works. You should have a pretty good idea of how to wire in the chip, but you probably have some questions on how to create useful inputs and outputs to see what’s happening. The output will simply consist of a resistor and a LED – when the chip’s output is high, the LED will be on. Providing the same function for the input, a LED that is on

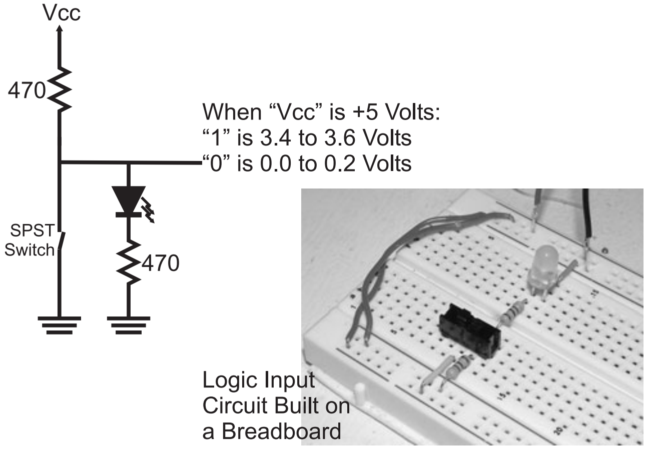

Fig. 3-37. Switch input circuit with LED.

when the input is high is a bit more difficult and uses the circuit shown in Fig. 3-37.

This input circuit probably seems to be much more complex than I have led you to believe is necessary, but there are some requirements that were important for this circuit to meet so that it could be used in a variety of different situations. The first requirement was that it had to work for both TTL (using 5 volt power) as well as CMOS logic (powered from 5 to 9 volts). By providing a direct path to ground, the low voltage requirement of CMOS logic and the current path to ground for TTL was provided. Next, it had to light a LED when the input was high and turn it off when the input was low; the switch will provide a zero impedance current path for the current from the positive power to bypass the LED. Finally, it had to be easy for you to wire and check over in case it doesn't seem to be working properly.

In Fig. 3-37, along with the logic input circuit schematic, I have included a photograph of the completed circuit built on a breadboard. In the photograph, notice that I have clipped the LED and resistor leads to keep the circuit as neat as possible on the breadboard. I strongly recommend that you keep components as close to the surface of the breadboard as possible to minimize your confusion when you are starting to build more complex circuits.

To demonstrate the operation of the inverter, you can build the circuit shown in the left side of Fig. 3-38 on your breadboard using the wiring diagram on the right side of Fig. 3-38. When the input LED is on, the output LED will be off and vice versa. If one or the other LED does not light, then first check your wiring followed by the polarity of the LEDs – the flat side of

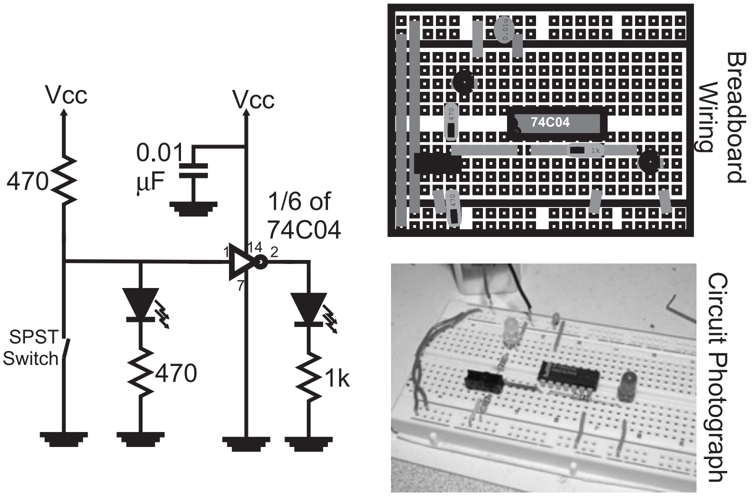

Fig. 3-38. Putting the input with an inverter.

the LED must be connected to the negative voltage (Vss) connection of your circuit.

To build the inverter test circuit, you will need the following parts:

- Breadboard
- 9 volt battery
- 9 volt battery clip
- 74C04 CMOS hex inverter chip
- Two 5 mm LEDs
- Two 470 Ω 1/4 watt resistors
- 1 k 1/4 watt resistor
- 0.01 µF capacitor (any type)
- Breadboard mountable switch (Digi-Key EG1903 suggested).

The only part that you might have some problems finding is the breadboard mountable switch (the EG1903 is a single-pole, double-throw switch with three posts 0.100 inch apart). This part is fairly unique and if you don't want to go through the trouble of ordering the part from Digi-Key, you can either add wires to another switch or simply connect the circuit to the Vss connection to simulate the switch closing (in this case, the LED will go off indicating a low input, just as if a switch were in circuit).

The 74Cxx family of chips are CMOS logic that are pin and output current compatible with 74LSxx TTL chips. The 74C04 used in the circuit shown in Fig. 3-38 demonstrates the operation of the NOT gate (or inverter) to quite good effect. The 74C04 does not demonstrate the operation of a TTL gate all

that well, so if you have a few moments, I suggest that you build the circuit shown in Fig. 3-39 (wired according to Fig. 3-40) and test it out – externally, it will seem to work identically to the 74C04 circuit shown in Fig. 3-38, but there are a few differences that you can experiment with.

The parts that you will need for this circuit are:

- Breadboard
- 9 volt battery
- 9 volt battery clip
- Four 2N3904 NPN bipolar transistors
- Two 1N914 (or equivalent) silicon diodes
- Two 5 mm LEDs
- 150 Ω 1/4 watt resistor

- Two 470 Ω 1/4 watt resistors
- 1 k 1/4 watt resistor
- 1.5 k 1/4 watt resistor
- 2.2 k 1/4 watt resistor
- 4.7 k 1/4 watt resistor
- 100 k 1/4 watt resistor
- 10 k potentiometer
- Breadboard mountable switch (Digi-Key EG1903 suggested).

Going through the circuit, you can see that current flows through the circuit in two different directions, as shown in Figs. 3-41 and 3-42. When the input is

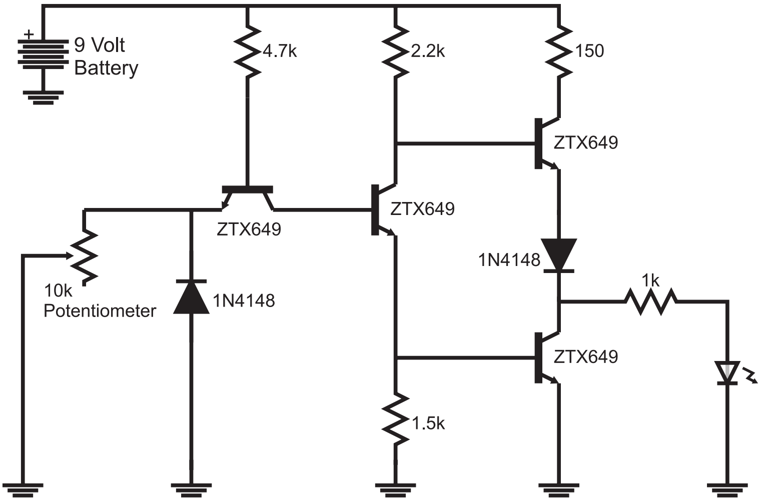

Fig. 3-43. Circuit to test current draw for TTL operation.

"high" (LED on) and you follow the current path, you will see that the current will ultimately turn on the bottom right transistor, connecting the gate's output pin to ground ("low" voltage output). When current is drawn from the TTL input pin (Fig. 3-42), the current that ultimately turned on the bottom right transistor is taken away, resulting in a different path for currents within the gate. This change in current flow ultimately turns on the top right transistor, effectively tying the output to power and driving out a "high" voltage.

Once you have built the circuit and tested it, you can now look at the operating aspects of it by putting a potentiometer in the circuit, as I have shown in Fig. 3-43, and adjust it until the LED either flashes on and off or dims. If you have a digital multi-meter (DMM), you will find that the *threshold* current is about 1 mA, with a voltage across the potentiometer of around 0.5 volts.

The final aspect of this experiment is to wire the inverter's input as shown in Fig. 3-44 and alternatively connect the input (passing through the 100 k resistor) to the power in or ground. You will find that the LED never turns on regardless of the switch position. If you were to measure the voltage at the 100 k resistor, you would see that it is connected directly to the power and ground connections, but the circuit seems to ignore the ground connection. The 100 k resistor prevents the 1 mA of current passing through to ground, resulting in the LED being turned on. If you were to repeat this experiment with the 74C04, you would see the LED turning on and off according to the voltage at the 100 k resistor.

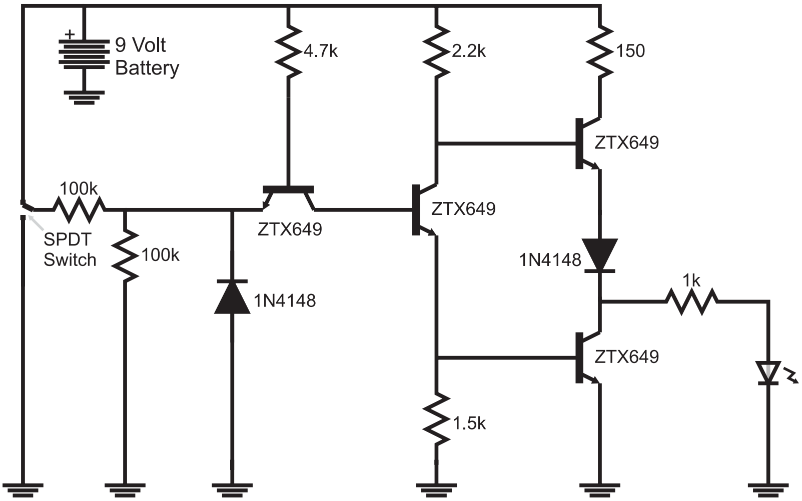

Fig. 3-44. Circuit to test voltage control of TTL operation.

In this chapter, I have given you a brief tutorial in basic electronics, an introduction to semiconductors and a method that you can use to build test circuits to experiment with digital electronics. In these few pages, I have covered the material included in several high school and college courses. It was not my intention to overwhelm you, but provide you with enough information to understand what is happening in a digital electronic circuit as well as give you a few basic rules to help you avoid problems, or if things aren't working as you would expect, to have some ideas on where to look for the problems.

Quiz

1. Electricity must:
   (a) Change polarity 60 times a second
   (b) Flow between the planets
   (c) Be equal in all parts of a circuit
   (d) Flow in a closed, continuous loop
2. Every electrical circuit has three parts:
   (a) Breadboards, batteries and electronic parts
   (b) Power source, load and conductors

(c) Intelligence, compassion and a sense of humor
(d) Speed, power (or torque) and corporeal form

3. In the water pipe/tap/hose example, if you were to partially close the tap:
   (a) Water would stream out faster from the hose
   (b) The tap would get hot in your hand from the friction of the water passing through it
   (c) The amount of water leaving the hose would decrease
   (d) The water leaving the hose would stream further

4. In a single resistor circuit, if you apply 9 volts and measure 100 mA flowing through it, the resistance value is:
   (a) 9 ohms
   (b) 900 ohms
   (c) 90 ohms
   (d) 1,111 ohms

5. The equivalent resistance of a 10 ohm and 20 ohm resistor in parallel:
   (a) Is always zero
   (b) 30 ohms
   (c) 7.5 ohms
   (d) 6.7 ohms

6. A diode is said to be "forward biased" when:
   (a) A positive voltage is applied to the "bar" painted on the side of the diode
   (b) Electrons are injected into the P-type semiconductor of the diode
   (c) Current flows into the diode through the end which doesn't have a band painted on it
   (d) More than 0.7 volts is applied to it

7. If a bipolar transistor with an h_{FE} of 150 had a "small signal operating region" base current of 1 μA to 1 mA, what base current would be required to allow 10 mA collector current?
   (a) This is impossible to answer because 10 mA collector current is greater than 1 mA.
   (b) 1 mA
   (c) 67 μA
   (d) 667 μA

8. The basic TTL gate is:
   (a) The NOT gate
   (b) The AND gate
   (c) The NOR gate
   (d) The NAND gate

9. Totem pole outputs are best used:
   (a) When there are multiple outputs tied together as a ‘‘dotted AND’’
   (b) To drive electric motors
   (c) As the default output type used in digital electronic circuits
   (d) When high-speed operation of the digital electronic circuit is required

10. The dual in-line package:
    (a) Is a standard method for packaging digital electronic chips
    (b) Is used because part numbers cannot be stamped on bare chips
    (c) Allows for an easy visual check to see whether or not the part was damaged by heat
    (d) Facilitates effective cooling to the chip inside

4

CHAPTER

Number Systems

Working through the book to this point, you should be comfortable with combining multiple single bit values together in a variety of different ways to perform different combinatorial circuit functions. Along with being able to meet the basic requirements, you should be able to optimize the circuit to the fewest number of gates that is available within the technology that you are going to use. This skill is very useful in itself, but it is only scratching the surface of what can be done with digital electronics; most data consists of more than a single bit (which can have only two values) to process, and working with multiple single bits of data can be cumbersome. What is needed is a methodology for combining bits together so they can represent larger values that can be simply expressed.

The solution to this issue is to combine bits in exactly the same way as a 10-value character is combined to produce the decimal numbers that you are familiar with. While on the surface, combining bits does not seem to be directly analogous to decimal numbers, by using the same method that decimal numbers are produced, multi-bit numbers (which are most often described as "binary") numbers can be produced.

In primary school, you learned that the four-digit number "1,234" was built out of four digits, any of which could have the 10 values "0", "1", "2",

Copyright © 2005 by The McGraw-Hill Companies, Inc. Click here for terms of use.

"3", "4", "5", "6", "7", "8" and "9". When listing the different values for a digit, zero is stated because the number "10" is actually a two digit number. The number of different values for each digit is referred to as its "base" or "radix". It is important to note that the first value is always zero and the last value is the base minus one.

When expressing each digit, its value was stated by the "column" it was in ("ones", "tens", "hundreds", "thousands", etc.). For example, the second column of "1,234" is the "hundreds" column and in 1234, there are two hundreds.

In high school, you would have been introduced to the concept of exponents and instead of expressing each digit in the number by the column, you would express it by the digit multiplier. So, 1,234 could now be written out as:

$$
\begin{aligned}
&\texttt{1 Thousand} = 1 \times 1{,}000 = 1 \times 10^3 \\
&\texttt{2 Hundreds} = 2 \times 100 = 2 \times 10^2 \\
&\texttt{3 Tens} \quad\;\; = 3 \times 10 = 3 \times 10^1 \\
&\texttt{4 Ones} \quad\;\; = 4 \times 1 = 4 \times 10^0
\end{aligned}
$$

The beauty of expressing a number in this way is that each digit's multiplier is mathematically defined as a power of the base. Using this format, it is possible to create a numbering system using single bits to represent "binary" numbers.

For example, four bits could be put together with the bit containing the least significant digit labelled "Bit_0", the second least significant as "Bit_1", the second most significant as "Bit_2" and the most significant as "Bit_3". The term significance when applied to bits is used to express the magnitude of the bit's multiplier. For example, Bit_0, which is multiplied by 2^0 or 1, has less significance than Bit_3 which is multiplied by 2^3 or 8.

Using the same exponent format as was used to define the decimal number 1,234, the four-bit binary number could be defined as:

$$
\begin{aligned}
&\texttt{Bit}_3 \times 2^3 \\
&\texttt{Bit}_2 \times 2^2 \\
&\texttt{Bit}_1 \times 2^1 \\
&\texttt{Bit}_0 \times 2^0
\end{aligned}
$$

and written out in a similar format to a decimal number. Collectively, the number is written out as a series of ones and zeros, in a similar manner to that of a decimal number.

Many books go into great length trying to explain how to convert a decimal number to a binary number. I won't go into the same amount of detail because the algorithm to do this is really quite simple: you simply start at some most power of two and work your way down, writing out a "1" for each time the subtraction the power of two results in a positive number or zero and a "0" when the difference is negative.

Written out as part of a "C" program, converting a decimal number to a character four-bit binary number is accomplished by the following statements:

```
for (i = 4; i! = 0; i − −)
    if ((DecVal − (2 ∗ ∗(i − 1)))> = 0)
    {                            //Can Take Away Digit Value
        DecVal = DecVal − (2 ∗ ∗(i − 1));
        Bit[i − 1] = `1´;
    } else                       //Result of subtraction is negative
        Bit[i − 1] = `0´;  //Can't take away value
```

Note that I start at "4" and subtract one for the actual bit value in the example code above.

Demonstrating the algorithm, consider the case where you wanted to express the decimal number "11" as a four-bit decimal. In Table 4-1, I have listed each step of the program with the variable values at each step.

Converting binary numbers to decimal is very easy because the power of two of each digit that has a value of "1" are summed together. The "C" code

Table 4-1 Converting decimal 11 to binary 1011.

'Bit' variable	i	DecVal	DecVal − ((2 ** (i − 1))
xxxx	4	11	3 (Positive)
1xxx	3	3	−1
10xx	2	3	1 (Positive)
101x	1	1	0 (Positive)
1011	0	0	N/A

Table 4-2 Converting binary 0110 to decimal 6.

'Bit' variable	i	Bit[i − 1] != 0?	DecVal
0110	4	No	0
0**1**10	3	Yes	4 (DecValue + (2 ** (3 – 1)))
01**1**0	2	Yes	6 (DecValue + (2 ** (2 – 1)))
011**0**	1	No	6
0110	0	N/A	6

to convert a value in "Bit" to a decimal value is:

```
DecVal = 0;                    // Initialize the Decimal
                                  Value Variable
for (I = 4; i> = 0; i − −)     // Repeat for four bits
   if(Bit[i − 1] == "1")      // Add Digit Value if Digit Not 0
     DecValue = DecValue + (2 ∗ ∗(i − 1));
```

In Table 4-2, I have listed the process of converting the binary number 0110 to decimal and you should note that I have highlighted the bit that is being tested.

Before going on, I would like to point out that there can be a lot of confusion with regards to using binary numbers with decimal numbers or numbers of different bases. To eliminate the confusion, you should always identify the binary numbers by placing a percentage sign ("%") or surrounding it with the letter "B" and two single quotes ("' "). Using these conventions, the bit pattern converted in Table 4-1 would be written out as %0110 or B'0110'. The % character put before a binary number is a common assembly language programming convention. The letter "B" and the single quotes around the number is the format used in "C" programming and will be the convention that I use in this book.

Another area of confusion with regards to binary numbers is how they are broken up for easier reading. Each group of three digits in a decimal number is usually separated from other groups of digits by use of a comma ("," in North America and a period or dot (".") in Europe and other parts of the world). When working with binary numbers, instead of separating each three digit group with a punctuation character, it is customary to use a blank to separate four digit groups. Using the conventions outlined here, the eight bit number 10111101 would be written out as:

`B'1011 1101'`

This is the binary number format convention that I will use for the rest of the book.

Base 16 or Hexadecimal Numbers

As I will show in this and the next section, having programming experience is a two-edged sword – it will help you understand certain concepts (such as the "bit" and some data structures like the ones presented in this and the next section), but it will blind you to other opportunities. The goal of these sections is to illustrate how bits can be grouped together to make your design efforts more efficient as well as making it easier for you to both see possibilities for the design and articulate them to other people.

Creating binary numbers from groups of bits, as I demonstrated in the introduction to this chapter, is quite easy to do, but can be very cumbersome to write out as well as transfer correctly. You may also have difficulty in figuring out exactly how to express the number, asking should it be passed along starting from the most significant or least significant bit. At the end of this chapter's introduction, I left you with the number B'1011 1101' and you should agree that telling somebody its value is quite cumbersome; for example, you might say something like, "The eight bit, binary number, starting with the most significant bit is one, zero, one, one, one, one, zero and one."

It is much more efficient to combine multiple bits together into a single entity or digit.

The most popular way of doing this is to combine four bits together as a "hexadecimal" digit which has 16 different values. This numbering system has a base of 16. If you are familiar with programming, chances are you are familiar with hexadecimal digits (which is often contracted to the term "hex"), which I have listed out with their decimal and binary equivalents in Table 4-3.

To create a way of expressing the 16 values, the first 10 hexadecimal values are the same as the 10 decimal number values, with the following six being given letter codes. This is why I included the "phonetic" values for the hexadecimal values greater than 9; the letter names "B", "C" and "D" can be easily confused, but their phonetic representations are much clearer.

Table 4-3 Hexadecimal digits with binary, decimal equivalents and phonetic values.

Decimal	Binary	Hex	Phonetic	Decimal	Binary	Hex	Phonetic
0	B'0000'	0	Zero	8	B'1000'	8	Eight
1	B'0001'	1	One	9	B'1001'	9	Nine
2	B'0010'	2	Two	10	B'1010'	A	Able
3	B'0011'	3	Three	11	B'1011'	B	Baker
4	B'0100'	4	Four	12	B'1100'	C	Charlie
5	B'0101'	5	Five	13	B'1101'	D	Dog
6	B'0110'	6	Six	14	B'1110'	E	Easy
7	B'0111'	7	Seven	15	B'1111'	F	Fox

I tend to place a lot of importance to using conventions when expressing letters. You may be tempted to make up your own letter codes or use the aviation phonetic alphabet (Table 4-4) when communicating hexadecimal values to other people ("AF" could be "Apple-Frank" or "Alpha-Foxtrot" instead of "Able-Fox"). I would like to discourage this for two reasons: the first is that the person you are talking to will have to mentally convert your words into letters and then hex digits – this process is complicated when unexpected words are used. Secondly, I prefer using the phonetic codes in Table 4-3 for hex values and the aviation phonetic codes for letter codes.

Multi-digit hexadecimal numbers are written out in a similar way as decimal or binary numbers with each digit multiplied by 16 to the power of the number of value's position. For a 16 bit number (four hexadecimal digits), the digit multipliers are listed below:

$$\mathtt{HexDigit}_3 \times 16^3 = \mathtt{HexDigit}_3 \times 4{,}096$$

$$\mathtt{HexDigit}_2 \times 16^2 = \mathtt{HexDigit}_2 \times 256$$

$$\mathtt{HexDigit}_1 \times 16^1 = \mathtt{HexDigit}_1 \times 16$$

$$\mathtt{HexDigit}_0 \times 16^0 = \mathtt{HexDigit}_0 \times 1$$

To indicate a hex number, you should use one of the programming conventions, such as putting the prefix "0x0" or "$" at the start of the hexadecimal

Table 4-4 Aviation phonetic codes.

Letter	Phonetic	Letter	Phonetic	Letter	Phonetic
A	Alpha	J	Juliet	S	Sierra
B	Beta	K	Kilo	T	Tango
C	Charlie	L	Lima	U	Uniform
D	Delta	M	Mike	V	Victor
E	Echo	N	November	W	Whiskey
F	Foxtrot	O	Oscar	X	X-Ray
G	Gulf	P	Papa	Y	Yankee
H	Hotel	Q	Quebec	Z	Zulu
I	India	R	Romeo		

value. The same formatting convention used with binary numbers (X'##', where "##" are the hex digits) could also be used. For this book, I will be expressing hexadecimal numbers in the format 0x0## which is visually very different from binary numbers, which should help to immediately differentiate them.

To convert a decimal number to a character 16 bit hexadecimal number, you can use the "C" algorithm shown below. Note that I have used the C modulo ("%") operation which returns the remainder from an integer division operation and not its dividend.

```
for (i = 16; i! = 0; i = i − 4)
{
  if ((DecVal/(16 ∗ (1<<(i − 8)))) > 9)
    Hex[(i/4) − 1] = (DecVal/(16 ∗ (1<<(i − 8)))) − 10 + `A´;
  else
    Hex[(i/4) − 1] = (DecVal/(16 ∗ (1<<(i − 8)))) + `0´;
  DecValue = DecValue%(16 ∗ (1<<(i − 8));
} //  rof
```

Going the other way, to convert a four hexadecimal digit number to decimal you can use the algorithm:

```
DecVal = 0;
for(i = 4; i! = 0; i − −)
   if((Hex[i − 1] >= “A”)&&(Hex[i − 1] <= “F”))
      DecVal = (DecValue ∗ 16) + (Hex[i − 1] − `A´ + 10);
   else
      DecVal = (DecValue ∗ 16) + (Hex[I − 1] − `0´);
```

Many books provide a conversion table between binary, hexadecimal and decimal numbers, but I would like you to be familiar with the conversion algorithms written out above as well as buy yourself an inexpensive scientific calculator which has ability to convert between base systems. The ability to convert between the base systems is actually quite simple and available in many basic scientific calculators which cost $10 or less. Understanding how to convert between base systems and having an inexpensive calculator will enable you to perform the conversions faster and with more flexibility than using a table, which is limited in the number of different values it can present.

If you are familiar with numbers in different languages, then you will know that the prefix ‘‘hex’’ actually refers to the number ‘‘six’’ and not ‘‘16’’. The actual prefix for 16 is the term ‘‘sex’’ and in the early days of computers, this was (obviously) a source of some amusement. When IBM introduced the System/360, in the early 1960s, the company was uncomfortable with releasing something that was programmed in ‘‘sexadecimal’’, fearing that it might upset some users. To avoid any controversy, all documentation for the System/360 was written using the 16 bit ‘‘hexadecimal’’ numbering system presented here. The System/360 was a wild success, becoming the first ‘‘computer for the masses’’ and many people’s first experience in programming and electronics. The term ‘‘hexadecimal’’ became the popular term for 16 bit numbers and displaced the more correct ‘‘sexadecimal.’’

Binary Coded Decimal

In the early days of programming, data structures were often the result of a curious blend of trying to come up with a data format that best suited the programmer and what best suited the current hardware. One of the more

Table 4-5 Decimal digits with binary and BCD decimal equivalents.

Decimal	Binary	BCD	Decimal	Binary	BCD
0	B’0000’	0	8	B’1000’	8
1	B’0001’	1	9	B’1001’	9
2	B’0010’	2	10	B’1010’	Invalid
3	B’0011’	3	11	B’1011’	Invalid
4	B’0100’	4	12	B’1100’	Invalid
5	B’0101’	5	13	B’1101’	Invalid
6	B’0110’	6	14	B’1110’	Invalid
7	B’0111’	7	15	B’1111’	Invalid

enduring structures that came from this time is the ‘‘binary coded decimal’’ (most often referred to by its acronym ‘‘BCD’’) which used four bits, like hexadecimal values, but only allowed the values of zero through nine rather than the full 16 values that were possible (as shown in Table 4-5). The reason for using this data structure has largely disappeared in computer systems, but it is still a viable and useful method of handling data in digital electronics and one that you should keep in your ‘‘hip pocket’’ when you design circuits.

The original reason for using the BCD data format in computer programming was its elimination of the need to add code to the program to convert a binary or hex number into decimal. The code storage required for the conversion was expensive and the processors were nowhere near as possible as what is available today. Using decimal values was actually an optimal way of processing data in these old systems.

The lasting legacy of this is the number of standard chips that can process BCD values just as easily as other standard chips can process hexadecimal values and will allow you to design circuitry that works with decimal values just as easily as if you were working with hex values.

While this is getting a bit ahead of things, I want to give the example of designing a delay that holds back a signal for 100 seconds. Using traditional binary logic, which only works with bits that are a power of two, you would have to design a circuit that compares a counter value and indicates when the value “100” was reached and reset itself. When using digital electronic chips that are designed for BCD values, the comparator function is not required, as each BCD digit cannot be greater than “9” and, cascaded together, they can only count to a maximum value of “99” to “00”.

This may seem like a trivial example, but you will find a number of cases like this one where you will have to create circuits that work on base 10 data and by using chips which are designed for BCD values, the complexity of your work will be greatly reduced.

Going back to Table 4-5, the production of the “invalid” indication is worthy of some discussion as it provides a good example of how gate optimization is not always as straightforward as you might expect.

In most BCD chips, if the value of 10 or more is passed in the binary bits, then the value is converted to zero and a carry indication is output. Using the tools presented in Chapter 2, you should be able to derive the sum of products formula for the positive active “invalid” indicator as:

$$\texttt{Invalid} = (\texttt{A3} \cdot \texttt{A2}) + (\texttt{A3} \cdot \texttt{A2})$$

and using the conversion formulas of Chapter 2, you would simplify the “invalid” formula above to:

$$\texttt{Invalid} = \texttt{A3} \cdot (\texttt{A2} + \texttt{A1})$$

Figure 4-1 shows the AND/OR gates for this function along with the “NAND equivalent” function beneath it. The NAND equivalent was chosen by assuming that the function would be implemented in TTL. While this circuit looks a bit complex, if you follow it through, you will find that it provides the same function as the AND/OR combination above it.

It will probably surprise you to find out that this circuit is not optimal by any measurement: you can do better in terms of the number of gates, the time

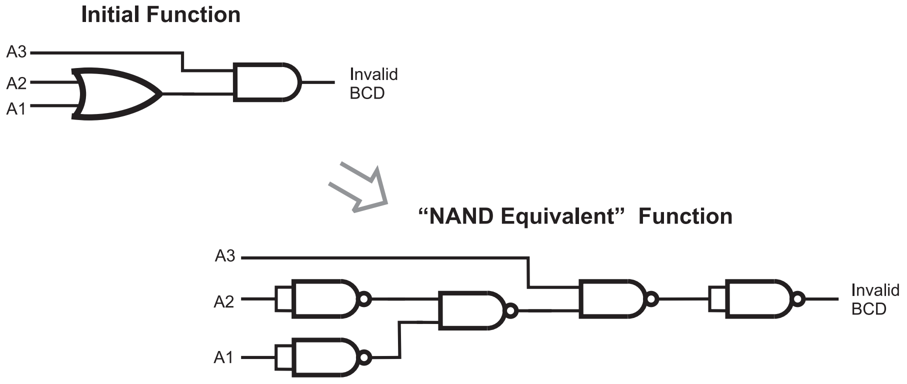

Fig. 4-1. Basic circuit for detecting values over “9” with reduction.

it takes a signal to pass through the gates and in providing a constantly timed output. The circuit at the bottom half of Fig. 4-1 will respond in two gate delays if A3 changes and in four gate delays if A2 changes. For many circuits, this is not a problem, but when you are working with high-performance designs, a variable output delay can result in the application not working correctly and being almost impossible to debug.

A much better approach to optimizing the circuit is to work at converting it to the basic gate used by the technology that you are working with and then optimizing this. Going back to the original "Invalid" equation:

$$\mathtt{Invalid} = (\mathtt{A3} \cdot \mathtt{A2}) + (\mathtt{A3} \cdot \mathtt{A2})$$

I can convert the OR to a NAND, by inverting its two parameters (according to De Morgan's theorem), ending up with:

$$\mathtt{Invalid} = \mathtt{!}(\mathtt{!}(\mathtt{A3} \cdot \mathtt{A2}) \cdot \mathtt{!}(\mathtt{A3} \cdot \mathtt{A2}))$$

It is probably astounding to see that the function provided by the mess of NAND gates in Fig. 4-1 can be reduced to the three simple gates required by the formula above. Along with reducing the number of gates, you should also notice that the maximum number of gate delays is two, regardless of which bit changes.

Looking at the NAND circuits in both diagrams, you are probably at a loss as to how you could reduce the NAND circuit in Fig. 4-1 to the three

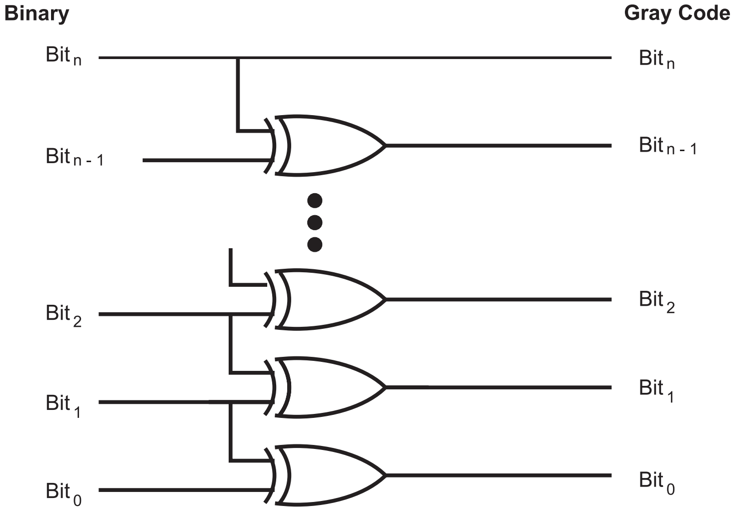

Fig. 4-2. Simple digital electronic circuit to convert a binary number to a Gray code.

gates of the optimized circuit. Personally, I would be surprised if you could; when I look at the two circuits, they look like they provide completely different functions.

What I want to leave you with is an example of how looking at a logic function from different perspectives can result in radically different circuits with surprisingly different parameters. In the first case, I reduced three gates to two, to end up with six NAND gates, while in the second, I avoided reducing the basic function and converted it directly to a much more efficient three NAND gate circuit.

In going through this exercise to produce the “invalid” output for BCD, I hope that you can apply this knowledge for creating circuits that work with different base systems than just a power of two. In some cases, you may have to work with numbers that are base 9 or 13 and using the example here, you should have some idea of how to keep the values within certain “bounds”.

Gray Codes

I hope I have convinced you of the usefulness of using Gray codes for inputs when you are illustrating how digital electronic logic functions respond to inputs. I must point out, however, that Gray codes were originally created for a much different function – they were designed for use in position sensors as the single changing bit allowed hardware to be designed to respond to a single changing bit and not the potentially several bits of a binary sequence. By only changing one bit at a time, absolutely precise positioning of marking sensors (causing all changing bits being sensed at the exact same instant) was not required.

Gray codes were invented by Frank Gray of Bell Labs in the mid 1950s and has a “hamming value” of 1. The hamming value is the number of bits that change between one value and the next. A four bit binary number can have all four bits change as it increments or decrements; a Gray code never has more than one bit change during incrementing or decrementing operations.

Chances are, you would not have any trouble coming up with a two bit Gray code (b’00’, b’01’, b’11’ and b’10’) and in a pinch, you would be able to come up with a three bit Gray code (b’000’, b’001’, b’011’, b’010’, b’110’, b’111’, b’101’ and b’100’). I suspect that if you were given the task of coming up with any more bits than this, you would be stumped.

In trying to come up with a way of explaining how Gray codes worked, I noticed that when a new most significant bit was set, the previous values were ORed with this bit, but written out in reverse order. In some texts, this property is recognized by calling Gray codes a *binary reflected code*. Looking at Table 4-6, you can see that I created a four bit

Table 4-6 Building Gray codes from previous value.

Binary value	Gray code	Comments
B'0000'	B'0000'	1 bit Gray code, Gray code = binary value
B'0001'	B'0001'	1 bit Gray code, Gray code = binary value
B'0010'	B'0011'	2 bit Gray code, last value of bit 1 (B'1') list ORed
B'0011'	B'0010'	2 bit Gray code, first value of bit 1 (B'0') list Used
B'0100'	B'0110'	3 bit Gray code, last value of bit 2 (B'10') list ORed
B'0101'	B'0111'	3 bit Gray code, next last value of bit 2 bit (B'11') list ORed
B'0110'	B'0101'	3 bit Gray code, next last value of bit 2 (B'01') list ORed
B'0111'	B'0100'	3 bit Gray code, first value of bit 2 (B'00') list ORed
B'1000'	B'1100'	4 bit Gray code, last value of bit 3 (B'100') list ORed
B'1001'	B'1101'	4 bit Gray code, next last value of bit 3 (B'101') list ORed
B'1010'	B'1111'	4 bit Gray code, next last value of bit 3 (B'111') list ORed
B'1011'	B'1110'	4 bit Gray code, next last value of bit 3 (B'110') list ORed
B'1100'	B'1010'	4 bit Gray code, next last value of bit 3 (B'010') list ORed
B'1101'	B'1011'	4 bit Gray code, next last value of bit 3 (B'011') list ORed
B'1110'	B'1001'	4 bit Gray code, next last value of bit 3 (B'001') list ORed
B'1111'	B'1000'	4 bit Gray code, first value of bit 3 (B'000') list ORed

Gray code by taking the eight values of the three bit code, reversing them and setting bit 3.

This could be written out as a computer program algorithm as:

```
for  (i = 1; i < #Bits; i + +)  //Loop Around for Each Code
     if(1 == i)                  // − Trivial Initial Case
     {
      GrayCode[0] = 0;  GrayCode[1] = 1;
     } else {                    //Copy Previous Codes with
                                   //New MSB Set
         for(j = (1 << (i − 1)),k = ((1 << (i − 1)) − 1);
          j < (1 << i); j + +,k − −)
            GrayCode[j] = (1 << (i − 1)) + GrayCode[k];
     }        //fi
```

This code demonstrates how Gray codes are produced, but is not the optimal method for producing Gray codes (it is actually an ‘‘order n_2’’ algorithm, which means that every time the number of bits is doubled, the amount of time required to produce the values is quadrupled). Along with this, it is not easy to create digital logic hardware that will create these codes.

Fortunately, individual binary codes can be converted to Gray codes using the circuit shown in Fig. 4-2, which simply implements the formula:

```
Gray Code = Binary ^ (Binary >> 1)
```

Going the other way (from Gray code to binary) is a bit more complex and while it uses n − 1 (where ‘‘n’’ is the number of bits) XOR gates, like converting binary codes to Gray codes, the output of each XOR gate is required as an input to the next least significant bit, as shown in Fig. 4-3. The output of the circuit is not correct until the most significant bit has passed through each of the XOR gates to the least significant bit.

To perform the data conversion a simple formula cannot be used. Instead the following algorithm is required:

```
GrayCode = Binary; Shift = 1;
While((GrayCode >> Shift)! = 0)
```

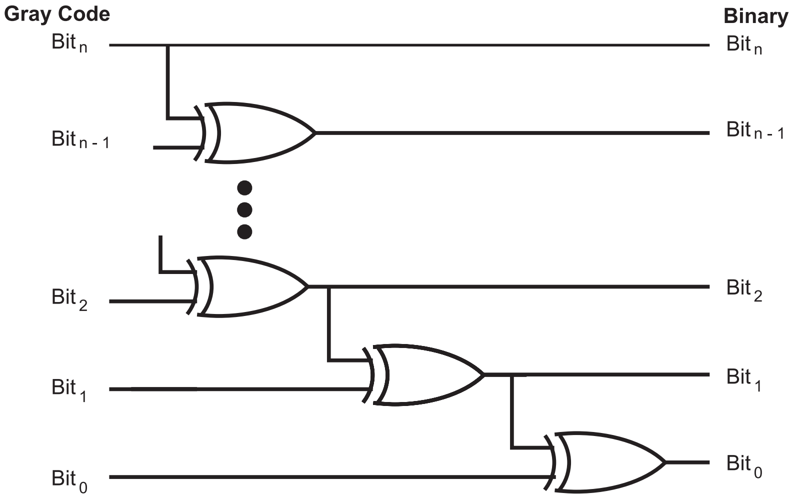

Fig. 4-3. Digital electronic circuit to convert a Gray code to a binary number.

```
  {
      GrayCode = GrayCode ^ (GrayCode >> Shift);
      Shift = Shift * 2;
  } //  elihw
```

I find it very difficult to explain exactly how this code works, except to say that with each iteration of the while loop, the "Gray code" value gets shifted down more and more to move the most significant bits into position for XORing with the less significant bits. To convince yourself that the algorithm works, you might want to perform a "thought experiment" on it and list the changing value of "Gray code" as I have done in Table 4-7.

In this chapter, more than anywhere else in the book, I have used sample computer programs to show how different values can be produced. This is a somewhat different approach to explaining how multi-bit binary data conversions are implemented and one that takes advantage of the ubiquity of the personal computer and the ability of most technical students to perform even rudimentary programming.

Using computer code to help demonstrate how the conversions are done should also give you another method for processing binary values as well as of testing formulas and optimizations. I always find it useful to have a number of different ways to solve a problem, or test a potential solution,

Table 4-7 Working through the shifting values of the Gray code convention algorithm.

Initial bit values	Shift = 1 bit values	Shift = 2 bit values	Shift = 4 bit values

B1	B1 ˆ B2	B1 ˆ B2 ˆ B3 ˆ B4	B1 ˆ B2 ˆ B3 ˆ B4 ˆ B5 ˆ B6 ˆ B7
B0	B0 ˆ B1	B0 ˆ B1 ˆ B2 ˆ B3	B0 ˆ B1 ˆ B2 ˆ B3 ˆ B4 ˆ B5 ˆ B6 ˆ B7

and I suggest that along with the various tools and computer algorithms presented in this book that you try to come up with methods for yourself that will help you design and test digital electronic circuits more efficiently.

Quiz

1. If you had a number system that was base 5, the most significant value in a digit would be:
   (a) 6
   (b) 10
   (c) 4
   (d) 5
2. The eight bit binary equivalent to decimal 47 is:
   (a) 0010 1111
   (b) B'0010 1111'

   (c) 101111
   (d) 1011 11

3. The third most significant digit in the decimal number "1234" is:
   (a) The hundreds column
   (b) 3
   (c) 1
   (d) No digit can be the third most significant
4. To verbally tell somebody the hex number value 0x04AC you would say:
   (a) "Four-Able-Charlie"
   (b) "Hexadecimal Four-Eh-See"
   (c) "Hexadecimal Four-Apple-Charlie"
   (d) "Hexadecimal Four-Able-Charlie"
5. The decimal number "123" in hexadecimal is:
   (a) 0x0123
   (b) B'0111 1011'
   (c) 7B
   (d) 0x07B
6. The four bit hexadecimal number 0x01234 expressed in decimal is:
   (a) 1,234
   (b) 4,660
   (c) B'0001 0010 0011 0100'
   (d) 0x04D2
7. Binary coded decimal is defined as:
   (a) Ten bits providing ten different values
   (b) Four bits providing ten numeric values and six control codes
   (c) Four bits providing ten numeric values
   (d) Five bits with each bit providing two values for a total of 10
8. BCD should:
   (a) Never be used
   (b) Used with circuits that operate with base 10 numbers
   (c) Only be used when you've run out of binary chips
   (d) Used when values are not expected to exceed 9
9. B'0110' in binary, using the formula $\text{Gray code} = \text{binary}\ \hat{}\ (\text{binary} \gg 1)$ can be converted to the Gray code:
   (a) B'1010'
   (b) B'0110'

(c) B’0101’
(d) B’0111’

10. The Gray code B’0010’ corresponds to the binary value:
(a) B’0011’
(b) Unknown because more data is required
(c) B’1101’
(d) B’0010’

5

CHAPTER

Binary Arithmetic Using Digital Electronics

Before going into showing how basic binary arithmetic operations are performed in digital electronic circuits, I thought it would be useful to review how you would perform basic arithmetic operations. Before discussing how many binary arithmetic operations there are, some different characteristics of binary numbers should be discussed. I realize that much of the material in this chapter introduction is a review of work that you first did in grade school, but often when confronted with situations that require you to develop binary arithmetic operations in digital electronics, this basic information can easily be forgotten and standard devices that provide this function are often overlooked.

Table 5-1 Necessary decimal addition pairs to memorize.

0 + 0									
0 + 1	1 + 1								
0 + 2	1 + 2	2 + 2							
0 + 3	1 + 3	2 + 3	3 + 3						
0 + 4	1 + 4	2 + 4	3 + 4	4 + 4					
0 + 5	1 + 5	2 + 5	3 + 5	4 + 5	5 + 5				
0 + 6	1 + 6	2 + 6	3 + 6	4 + 6	5 + 6	6 + 6			
0 + 7	1 + 7	2 + 7	3 + 7	4 + 7	5 + 7	6 + 7	7 + 7		
0 + 8	1 + 8	2 + 8	3 + 8	4 + 8	5 + 8	6 + 8	7 + 8	8 + 8	
0 + 9	1 + 9	2 + 9	3 + 9	4 + 9	5 + 9	6 + 9	7 + 9	8 + 9	9 + 9

When you first learned to add decimal numbers together, you probably were required to memorize all 100 different combinations of single digit parameters when only 55 are really required. In Table 5-1, I have listed the 55 pairs which have to be memorized; the remaining 45 pairs do not have to be memorized because of the commutative law which states:

$$A + B = B + A$$

and means that the number pairs like "4 + 7" and "7 + 4" are equivalent.

The result of adding each of these two parameters produces either a single digit or double digit sum. The double digit sum indicates that the value of the result is greater than could be represented in a single digit of the number base. For decimal numbers, the maximum value that can be represented by a single digit is "9". Looking at the general case, the maximum value that can be represented by a number system is the base minus one. So, for the binary number system (base 2), the maximum value is "1"; for hexadecimal (base 16), the maximum value is "15" (or "0x0F").

The leftmost digit of a double digit number is known as the "carry" digit.

In Chapter 4, I showed how multi-digit numbers are made up of single digit values multiplied by powers of their base. Knowing the sums of the 55 addition pairs of Table 5-1, multi-digit numbers can be added together

Sum of Addition Operation

Fig. 5-1. The process steps used to add two three digit numbers together.

by working through pairs of numbers, as I show in Fig. 5-1. This is a rather pedantic way of showing addition and I'm sure that when you add two multi-digit numbers together, you are much more efficient, but when you were learning, this was probably the process that you went through.

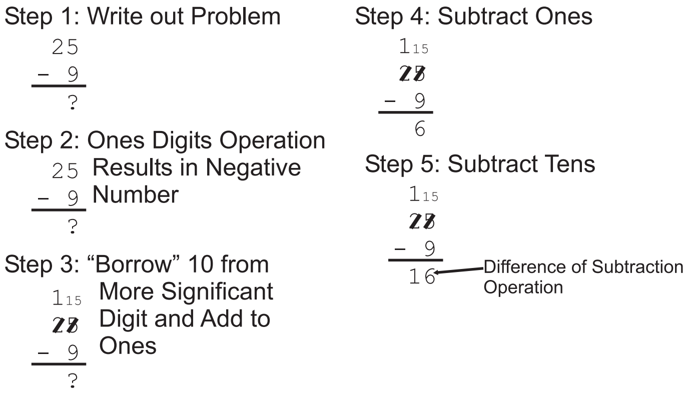
While saying that you are much more efficient, it really comes down to the idea that you are able to recognize that one plus another number is the same as incrementing the other number. You are still only adding one digit at a time and the carry is "rippling" to the next significant digit. Carry "ripple" is an important concept that will be discussed in more detail in the next section.

Subtraction has many of the same issues as addition, but with some additional complexities. The first being that you cannot simplify your memorization of the 100 pairs of subtracted parameters as you did for addition; the commutative law does not apply to subtraction as it did for addition. For example,

$$6 - 4 \neq 4 - 6$$

Next, if the number being taken away is greater than the original number, the result (or "difference") could be less than 0 or "negative". There is a very big question on how to represent that negative number. Typically, it is represented as a value with a "minus" or "subtraction" sign in front of it, e.g. "-2".

The minus sign is only used when the digit cannot "borrow" from the next significant digit, as shown in Fig. 5-2. The result of 25 minus 9 is 16, with the ones borrowing 10 from the tens column (the next significant digit) to allow the operation to proceed without a negative result.



Step 1: Write out Problem

Difference of Subtraction Operation

Fig. 5-2. Multi-digit subtraction with borrowing.

Subtraction can also be expressed as adding a negative value and can be written out as:

$$A - B = A + (-B)$$

This should not be a surprise to you unless you consider the following philosophical question: What would happen if infinity was arbitrarily defined as one million (1,000,000)? Instead of adding a minus sign to our value to make it negative, we could subtract it from "infinity".

For example, if we had the problem:

$$8 - 5 = 8 + (-5)$$

we could define "−5" as one million subtract 5 or "999,995". Now, going back to the addition of the negative number and substituting in "999,995" for "−5" we get:

$$\begin{aligned} 8 - 5 &= 8 + (-5) \\ &= 8 + 999{,}995 \\ &= 1{,}000{,}003 \end{aligned}$$

Since a million is defined as infinity and has no meaning, it can be taken away from the result, leaving us with the difference of 8 minus 5 being "3". This method may seem to be overly complex, but I will show you how this applies to digital electronics later in the chapter.

Like addition, the method presented here for subtraction is carried out a single digit at a time with the need to borrow from the next more significant digit being similar to passing the carry digit in addition. Like the "ripple carry" in addition, the "borrow" in subtraction can also be thought of as a "ripple" operation.

Multiplication and division have, not surprisingly, many of the same issues and when I discuss them later in this chapter, I will review them with you. Before reading the section discussing multiplication and division, I suggest that you review these operations and try to think of how they can be accomplished using digital electronics.

Adders

The circuit shown in Fig. 5-3 will add two bits together and output the sum ("S") bit along with a carry ("C") bit, if both inputs are "1" and the sum is "2", which is greater than the maximum number that can be represented by the number base (which is 1 for binary). Table 5-2 is a truth table, showing the output of each bit for different input values. You should be able to see that the "sum" bit is 1 when one or the other (but not both) of the two input bits is 1 and the "carry" bit is 1 only when both input bits are 1.

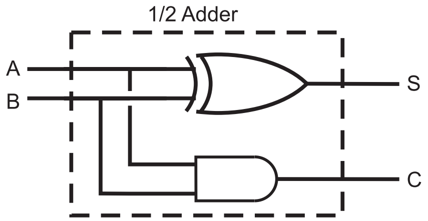

Fig. 5-3. Half adder circuit.

Table 5-2 Half adder operation truth table.

0	0	0	0
0	1	1	0
1	1	0	1
1	0	1	0

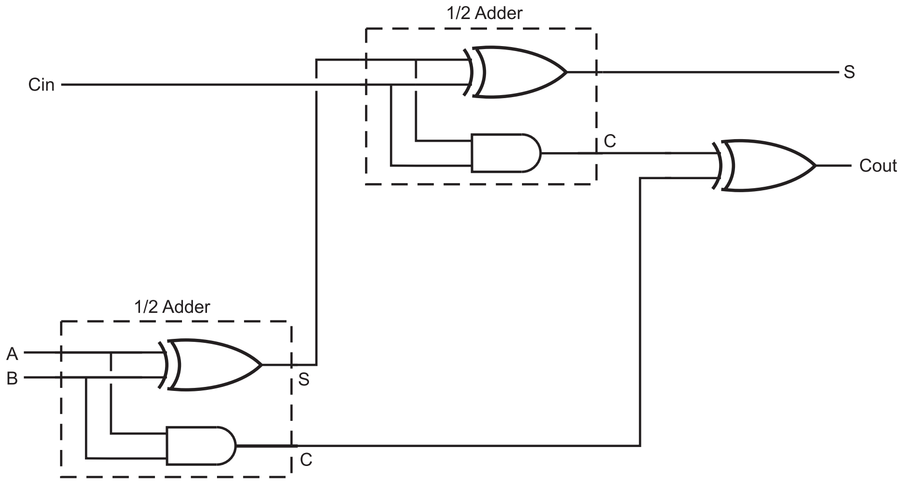

Fig. 5-4. Full adder circuit.

The adder is the first practical use most people have for the XOR gate and its function can be seen very clearly in Table 5-2 for the sum bit. Along with the XOR gate providing the function for the sum bit, you should also recognize that the carry bit is the output of a simple AND gate.

This simple digital electronic circuit is known as a ‘‘half adder’’ because it will handle half the operations required of the general case addition circuit. The ‘‘full adder’’ (Fig. 5-4) starts with a half adder and adds another bit (which is the less significant bit’s ‘‘carry’’ output) to its sum. Put another way, the full adder adds three individual bits together (two bits being the digit inputs and the third bit assumed to be carry from the addition of the next least-significant bit addition operation, known as ‘‘C_{in}’’).

You can analyze the operation of the full adder to check on its operation. The sum bit is 1 only if one or three of the input bits is 1. In the half adder, I showed that the sum bit could be written out as:

$$\mathtt{Sum} = \mathtt{A} \otimes \mathtt{B}$$

and should only be ‘‘1’’ if only one of the two inputs was 1. To understand the logic required to produce the sum bit for the three bit full adder, I created Table 5-3 in which the XOR output of the A and B inputs was given a single column entry. From the data presented in this table, you can see that the sum could be expressed as:

$$\mathtt{Sum} = (\mathtt{A} \otimes \mathtt{B}) \otimes \mathtt{C}$$

Table 5-3 Full adder sum bit operation truth table.

“A ⊗ B”	**“C_{in}” bit**	**“Sum” bit**
0	0	0
0	1	1
1	1	0
1	0	1

which, if you look back at Fig. 5-4, is exactly how it is implemented in the “full adder”.

The carry output bit is 1 if two or three of the input bits are 1. As an exercise, you may wish to create a truth table and reduce it down to see if you can match the carry gate logic of Fig. 5-3, but you can write out and reduce a sum of products equation quite easily:

$$
\begin{aligned}
\mathtt{Carry} &= (A \cdot B \cdot !C_{in}) + (!A \cdot B \cdot C_{in}) \\
&\quad + (A \cdot !B \cdot C_{in}) + (A \cdot B \cdot C_{in}) \\
&= (!C_{in} \cdot (A \cdot B)) + (C_{in} \cdot (A \cdot B)) \\
&\quad + (C_{in} \cdot (A \cdot !B) + (!C_{in} \cdot (!A \cdot B) \\
&= ((!C_{in} + C_{in}) \cdot (A \cdot B)) + (C_{in} \cdot (A \cdot !B)) \\
&\quad + (C_{in} \cdot (!A \cdot B)) \\
&= (A \cdot B) + (C_{in} \cdot ((!A \cdot B) + (A \cdot !B))
\end{aligned}
$$

Knowing that

$$((!A \cdot B) + (A \cdot !B)) = A \otimes B$$

the equation for the carry output of the full adder can be written out as:

$$\mathtt{Carry} = (A \cdot B) + ((!A \otimes B) \cdot C_{in})$$

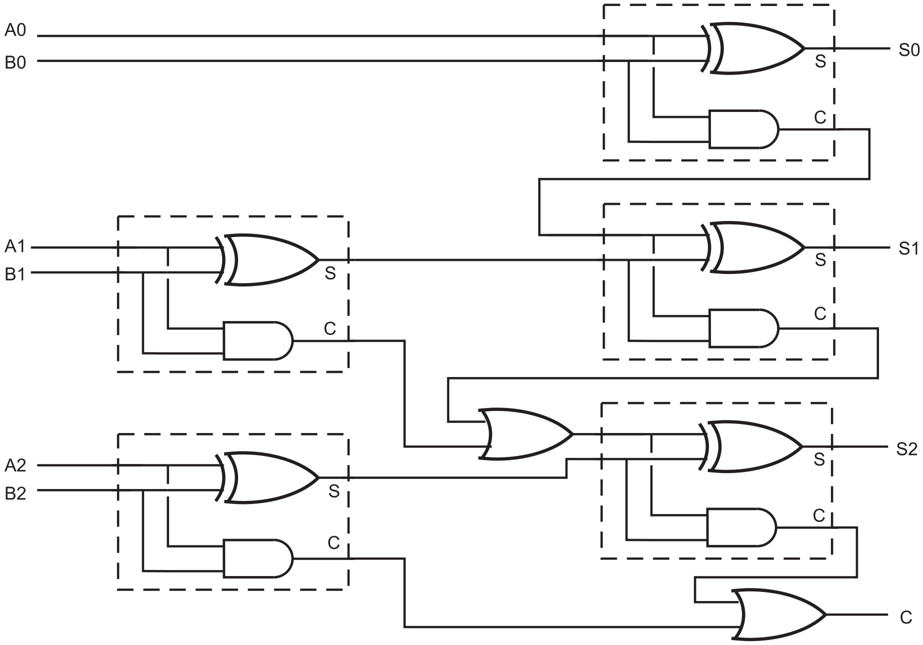

Fig. 5-5. Three bit "ripple adder" circuit.

which is *exactly* the carry logic circuit shown in Fig. 5-2. This type of analysis is useful to do when you are trying to puzzle out what a circuit is doing or to confirm that it is doing exactly what you expect it to do. It is also good practice of using the logic equation optimization skills first presented in Chapter 2.

Multiple full adders can be chained together (like in Fig. 5-5) to produce a multi-bit adder in which the carry results for each bit "ripples" through the various adder circuits. For most applications, this "ripple carry adder" can be used safely, but in something like your PC's processor, where quite a few bits are required and the adder is expected to execute quickly, the time required for the carry to ripple through the adders is prohibitive.

The solution to this problem is the "carry look-ahead" adder in which each bit takes not only the appropriate bits for input but also all the least significant bits that can affect the bit. The length of time the carry look-ahead adder needs to produce a sum is generally independent of the number of bits in the operation (unlike the time the ripple adder requires to produce a sum which is a function of the number of bits). Table 5-4 lists the different inputs and expected outputs for a three bit carry look-ahead adder. Reducing the

Table 5-4 Carry look-ahead adder input/output truth table.

information from this table, I have listed the equations for the three sum bits and the carry bit below:

$$\begin{aligned}
\texttt{S0} &= (\texttt{A0}\otimes\texttt{B0})\\
\texttt{S1} &= ((\texttt{A0}\otimes\texttt{B0})\cdot(\texttt{A1}\otimes\texttt{B1}))\\
&\quad+((\texttt{A1}\otimes\texttt{B1})\cdot!(\texttt{A0}+\texttt{B0}))\\
&\quad+(!(\texttt{A1}\otimes\texttt{B1})\cdot(\texttt{A0}\cdot\texttt{B0}))\\
\texttt{S2} &= ((\texttt{A2}\otimes\texttt{B2})\cdot!(\texttt{A2}\cdot\texttt{B2}))\\
&\quad+(!(\texttt{A2}\otimes\texttt{B2})+(\texttt{A1}\cdot\texttt{B1}))+(!(\texttt{A2}\cdot\texttt{B2})\\
&\quad+(\texttt{A1}\otimes\texttt{B1})\cdot(\texttt{A0}\cdot\texttt{B0}))\\
\texttt{Carry} &= (\texttt{A2}\cdot\texttt{B2})+((\texttt{A2}\otimes\texttt{B2})\cdot(\texttt{A1}\cdot\texttt{B1}))\\
&\quad+(\texttt{A2}\otimes\texttt{B2})\cdot(\texttt{A1}\otimes\texttt{B1})\cdot(\texttt{A0}\cdot\texttt{B0}))
\end{aligned}$$

It was a major effort on my part to reduce the equations for each sum bit and the carry bit. To do this, I used the truth table reduction method discussed in Chapter 2. To reduce the number of terms in the resulting sum of products equations, I first deleted all the instances where the specific bit was not "1"–in every case, this reduced the number of instances by half. Next, I worked at combining instances that were similar and found that rather than combining "don't care" bits, I found a number of places where two bits were XORed together. In the resulting equations, I kept the "XOR" terms in, even though when the "technology optimization" stage of the development effort is completed, these gates will be reduced to the technology's basic gates.

If you read through the equations and try to understand them, you will find that they do make a kind of sense. Obviously, as more bits are added to the carry look-ahead adder, the circuit becomes much more complex. Despite this complexity, the carry look-ahead is the most efficient way to provide an adder circuit for large bit words in fast applications.

Subtraction and Negative Numbers

As you might expect, binary subtraction has many of the same issues as addition, along with a few complexities that can make it harder to work with. In this section, I will introduce some of the issues in implementing a practical "subtracter" as well as look at some ways in which subtraction can be implemented easily with an existing addition circuit.

To make sure we're talking the same language, I want to define the terms that I will be using to describe the different parts of the subtraction operation. The "horizontal" arithmetic equation:

```
Result = A - B
```

can be written out "vertically" as:

```
      A  <- Minuend
     -B  <- Subtrahend
 ------
 Result  <- Difference
```

The "minuend" and "subtrahend" terms are probably something that you forgot that you learned from grade school. I use them here because they are less awkward than referring to them as the "value to be subtracted from" and the "value subtracted". The term "difference" as being the result of a subtraction operation is generally well understood and accepted.

When you carry out subtraction operations, you do it in a manner that is very similar to how you carry out addition; each digit is done individually and if the digit result is less than zero, the base value is "borrowed" from the next significant digit. With the assumption that subtraction works the same way as addition, you could create a "half subtracter", which is analogous to the half adder and could be defined by the truth table shown in Table 5-5

The "difference" bit is simply the minuend and subtrahend XORed together, while the "borrow" bit (decrementing the next significant digit) is only true if the minuend is 0 and the subtrahend is 1. The borrow bit can be defined as the inverted minuend ANDed with the subtrahend. The equations

Table 5-5 "Half subtracter" defining truth table.

Minuend	Subtrahend	Difference	Borrow
0	0	0	0
0	1	1	1
1	1	0	0
1	0	1	0

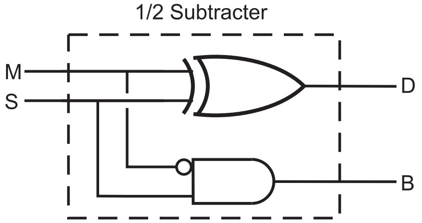

Fig. 5-6. Half subtracter circuit.

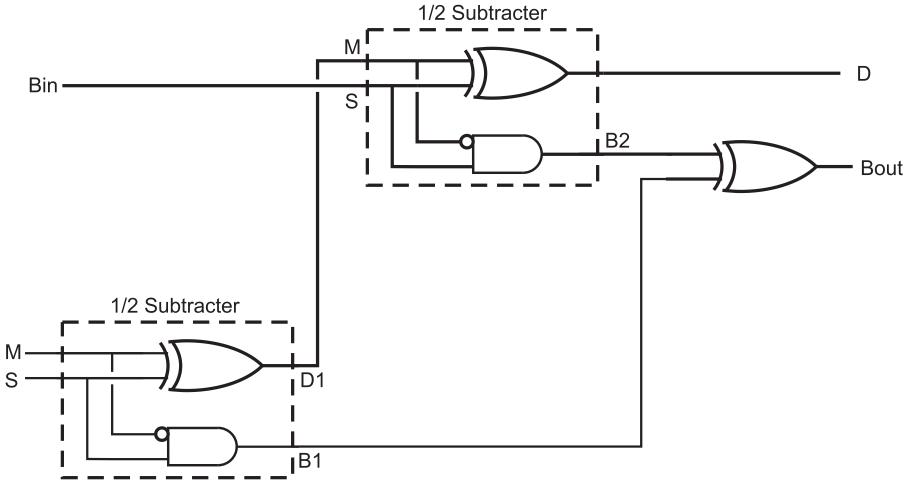

Fig. 5-7. Full subtracter circuit.

for the half subtracter are listed below and the subtracter building block is shown in Fig. 5-6.

$$\texttt{Difference} = \texttt{Minuend} \otimes \texttt{Subtrahend}$$
$$\texttt{Borrow} = !\texttt{Minuend} \cdot \texttt{Subtrahend}$$

The small circle on the single input indicates that the value is inverted before being passed into the gate. This convention avoids the need for putting a full inverter symbol in the wiring diagram of a digital circuit and is often used in chip datasheets to indicate inverted inputs to complex internal functions.

Two half subtracters can be combined into a "full subtracter", just as two half adders can be combined to form a full adder (Fig. 5-7). In Fig. 5-7, I have labeled the two half subtracters, so that their operation can be listed in Table 5-6, to test the operation of the full subtracter.

Table 5-6 Full subtracter operation truth table.

Bin	Minuend ("M")	Subtrahend ("S")		D1	B1	D	B2	Bout
0	0	0		0	0	0	0	0
0	0	1		1	1	1	0	1
0	1	1		0	0	0	0	0
0	1	0		1	0	1	0	0
1	1	0		1	0	0	0	0
1	1	1		0	0	1	1	1
1	0	1		1	1	0	0	1
1	0	0		0	0	1	1	1

Like the ripple adder, full subtracters can be chained together to create a multi-bit subtracter circuit (Fig. 5-8) and a "borrow look-ahead" (to coin a phrase) subtracter could be designed, but instead of going through the pain of designing one, there is another option and that is to add the negative of the subtrahend to the minuend.

In the introduction to this chapter, I introduced the idea of negative numbers as being the value being subtracted from an arbitrary large number and showed an example that produced "−5" in a universe where infinity was equal to one million. When you first went through this example, you might have thought that this was an interesting mathematical diversion and an illustration as to how negative and positive numbers converge when they approach infinity. This concept, while seemingly having little application in the "real world", is very useful in the digital domain.

In the digital domain, the term "infinity" can be replaced with "word size" and if the most significant bit of the word is considered to be the "sign" bit, positive and negative numbers can be expressed easily. In Table 5-7, I have listed the decimal, hex as well as the positive and negative values which take into account that a negative number can be written as:

$$-\mathtt{A} = \mathtt{Word\ Size} - \mathtt{A}$$

This negative value is known as a "two's complement" negative number and is the most commonly used negative bit format used. There is a "one's

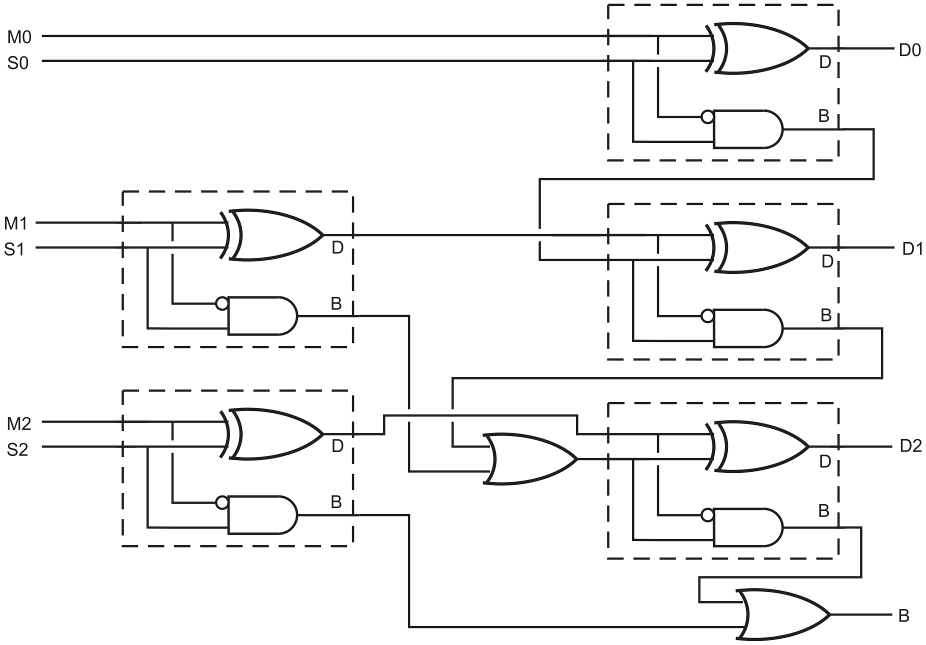

Fig. 5-8. Three bit "ripple subtracter" circuit.

complement" number format, but it does not avail itself as efficiently as two's complement to allow for easier subtraction and addition of negative numbers.

Looking at the formula above, you are probably confused as to why it would be used because it requires both a subtraction operation as well as an addition operation to carry out one subtraction operation. Negating a number in two's complement format does not actually require a subtraction operation; it can be done by inverting each bit (XORing each bit with 1) and then incrementing the result. Using the values of Table 5-7, you can demonstrate how a positive value is negated.

For example, to negate the value "5", the following steps are used:

1. Each bit of the number is XORed with "1". B'0101' becomes B'1010'.
2. The XORed result is incremented. B'1010' becomes B'1011', which is "−5".

The opposite is also true: the individual bits can be inverted and the result incremented to convert a negative two's complement value to a positive.

Once the value has been negated, it can be simply added to the other parameter, as I show in Fig. 5-9. There are three things that you should be

Table 5-7 Different ways of representing a four bit number.

Binary value	Decimal value	Hex value	Two's complement value
B'0000'	0	0x00	0
B'0001'	1	0x01	1
B'0010'	2	0x02	2
B'0011'	3	0x03	3

B'1000'	8	0x08	−8
B'1001'	9	0x09	−7
B'1010'	10	0x0A	−6
B'1011'	11	0x0B	−5
B'1100'	12	0x0C	−4
B'1101'	13	0x0D	−3
B'1110'	14	0x0E	−2
B'1111'	15	0x0F	−1

aware of before leaving this section. The first is the use of the "V" shaped mathematical function symbols in Fig. 5-9; these symbols indicate that two parameters are brought together to form one output. I use this symbol when a group of bits (not just one) are passing through the same operation.

You might be wondering why instead of simply inverting the individual bits of the value to be converted to a negative two's complement value, I XOR the bits with the value 1. The reason for doing this is in the interests

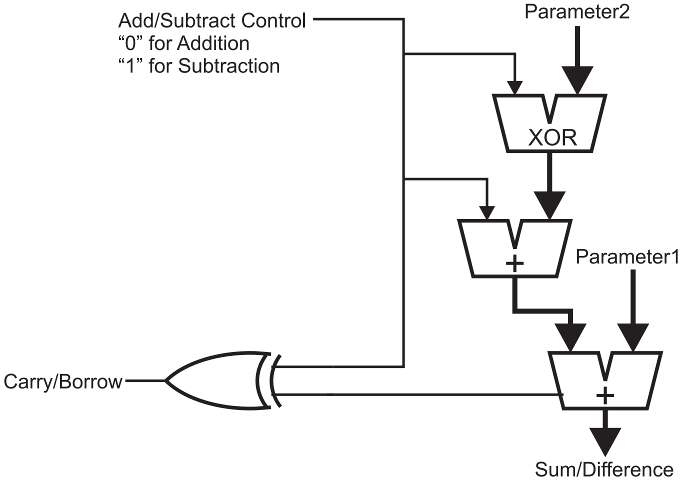

Fig. 5-9. Integrated adder/subtracter circuit.

of practicality and looking ahead. In Fig. 5-9, I show a circuit in which two parameters can be added together or one can be subtracted by the other – the "switch" control for which operation is selected. If a 1 is passed to the "Parameter2" circuitry, each bit of Parameter2 is XORed with 1, inverting each bit and a 1 is passed to the Parameter2 adder, which increments the value. If a zero is passed to the Parameter2 circuitry, the bits of Parameter2 are not inverted and zero is added to the output of the XOR function, resulting in an unchanged value of Parameter2 being passed to the adder with Parameter1. To net it out, if a "1" is passed to this circuit, Parameter2 is subtracted from Parameter1; if a "0" is passed to the circuit, the two parameters are added together.

The last point to note is that the "carry" output of the final adder is a negated "borrow" output when the subtraction operation is taking place. To integrate the operation of the "carry/borrow" bit with the add/subtract switch bit, this bit is set when a carry or borrow of the next significant word is required, regardless of the operation.

Magnitude Comparators and Bus Nomenclature

Along with being able to add and subtract binary values, you will find the need to compare binary values to determine whether or not a value is less than, equal to or greater than another value. Just as if this were a programming requirement, to test two binary values together, you would subtract one from the other and look at the results. An important issue when comparing a value made up of multiple bits is specifying how it is to be represented in logic drawings and schematic diagrams. In the previous section I touched on both these issues, in this section, I want to expand upon them and help you to understand a bit more about them.

When you are comparing two binary values, you are comparing the *magnitude* of the values, which is where the term “magnitude comparator” comes from. The typical magnitude comparator consists of two subtracters which either subtract one value from another and vice versa or subtract one value from another and then compare the result to zero. In either case, the magnitude comparator outputs values indicating which value is greater than the other or if they are equal.

Figure 5.10 shows a basic comparator, which consists of two subtracters utilizing the negative addition discussed in the previous section. The differences are discarded, but the !borrow outputs are used to determine if the negative value is greater. If the !borrow outputs from the two

subtracters are both equal to “1”, then it can be assumed that the two values are equal.

If one value is subtracted from the other to determine if one is lower than the other and if the value is not lower (i.e. !borrow is not zero), the result can then be compared to zero to see if the value is greater than or equal to the other. This method is probably less desirable because it tends to take longer to get a valid result and the result outputs will be valid at different times. Ideally, when multiple outputs are being produced by a circuit, they should all be available at approximately the same time (which is the advantage of the two subtracter circuit shown in Fig. 5-10 over this one).

If you are working with TTL and require a magnitude comparator, you will probably turn to the 7485, which is a four bit magnitude comparator consisting of two borrow look-ahead subtracters to ensure that the outputs are available in a minimum amount of time and are all valid at approximately the same time.

In Fig. 5-10 (as well as the multi-bit subtracter shown in the previous section), I contained related multiple bits in a single, thick line. This very common method of indicating multiple related bits is often known as a “bus”. Other methods include using a line of a different color or style. The advantage of grouping multiple bits that function together like this should be obvious: the diagram is simpler and it is easier to see the path that related bits take.

When I use the term “related bits”, I should point out that this does not only include the multiple bits of a binary value. You may have situations where busses are made up of bits which are not a binary value, but perform a similar function within the circuit. For example, the memory control lines for a microprocessor are often grouped together as a bus even though each function is provided by a single bit (memory read, memory write, etc.) and they are active at different times.

As well as indicating a complete set of related bits, a bus may be broken up into subsets, as shown in Fig. 5-11. In this diagram, I have shown how two four bit magnitude comparators can be “ganged” together to provide a comparison function on eight bits. The least significant four bits are passed to the first magnitude comparator and the most significant four bits are passed to the second magnitude comparator. The bits are typically listed as shown in Fig. 5-11, with the most significant bit listed first and separated from the least significant bit by a colon. In very few cases will you see the width of the bus reduced to indicate a subset of bits as I have done in Fig. 5-11; most design systems will keep the same width for a bus, even if one bit is being used in it.

Fig. 5-11. Cascading two four bit comparators.

Before going on, I want to make some comments about Fig. 5-11 as it provides a function that is often required when more bits must be operated on than is available by basic TTL or CMOS logic chips. To carry out the magnitude comparison operation on eight bits, I used two four bit magnitude comparator chips (modeled on the 7485) with the initial state inputs (marked ‘‘Initial Inputs’’ on Fig. 5-11) to start the chip off in the ‘‘neutral’’ state as if everything ‘‘upstream’’ (before) was equal to each other and the chip’s bits as well as any ‘‘downstream’’ (after) bits will determine which value is greater or if the two values are equal. This is a typical method for combining multiple chips to provide the capability to process more bits than one chip is able to.

Multiplication and Division

As you’ve read through this chapter, you should have noticed that there are usually many different ways of implementing different digital electronics functions. Each of the different implementation methods have their own advantages and tradeoffs – it is up to the application designer to understand what are the important ones. Nowhere is this more true than when you start discussing multiplication and division; there are a number of different methods of performing these arithmetic operations, each with their own characteristics.

Off the top of my head, I can come up with five different ways to multiply two binary numbers together. Before listing the different methods, I should make sure that I have defined the terms used in multiplication. The "multiplicand" is the value that is multiplied by the "multiplier" and typically remains static. The "multiplier" is the number of times that the multiplicand is added together to form the result or "product".

It should go without saying that if you had to multiply by a power of 2 (i.e. 1, 2, 4, 8, 16, etc.) a true multiplication operation is not required at all; the operation can be accomplished by shifting the multiplicand. For example to multiply a value by 4, you would simply shift the value to the left two times. Division is the same, except the value is shifted to the right.

Understanding the basic terms "multiplier" and "multiplicand" leads to a second method to implement a multiplication function in software – the multiplicand is added multiplier number of times to the product. It can be written out in "C" as:

```
Product = 0;                      //Clear result accumulator
for (i = 0; i < Multiplier; i++)
                                 //Repeatedly add Multiplicand
    Product = Product + Multiplicand;
```

This method is painfully slow (especially for large multiplier values) and is difficult to implement in combinatorial digital logic. It is also different from the method which you were taught in school in which the multiplicand is shifted up by the radix for each digit of the multiplier. Using this method, "123" decimal is multiplied by "24" decimal in the format:

```
     123
×     45
    ----
     615
+   492   < -Sum Products of each digit
    ----
    5535
```

In the first line of the solution, I multiplied the multiplicand "123" by the least significant digit of the multiplier followed by multiplying the multiplicand by 10 (the radix) followed by the next significant digit of the multiplier. Once the multiplicand has been multiplied by each digit of the multiplier (along with the appropriate multiplication of the digit position), each product is added together to get the final result.

This method lends itself extremely well to working within binary systems. Rather than multiplying the multiplicand repeated by the radix for each digit, the multiplicand is simply shifted to the right (which is multiplying by two) for each bit of the multiplier. If the multiplier bit is zero, then the value added to the product is zero. The binary multiplication operation for 123 by 45 is:

```
            B′01111011′
          × B′00101101′
           B′01111011′      < – Bit 0 of Multiplier is not Zero
          B′00000000′       < –Bit 1 of Multiplier is Zero
         B′01111011′        < –Bit 2
        B′01111011′         < –Bit 3
       B′00000000′          < –Bit 4
      B′01111011′           < –Bit 5
     B′00000000′            < –Bit 6
 +  B′00000000′             < –Bit 7
  B′0001010110011111′       < – Product (5,535 Decimal)
```

This is much more efficient than the previous version in terms of execution time and not significantly more complex than the other version. The “C” code that implements it is:

```
Product = 0;                              //Clear result accumulator
for (i = 0; i < log 2 (Multiplier); i ++)
{
     if ((Multiplier & 1) == 1)       //If LS Bit Set, Add Current
     Product = Product + Multiplicand;           //to Product
     Multiplier = Multiplier >>1; //Shift down Multiplier
     Multiplicand = Multiplicand << 1;    //Shift up
                                                 //Multiplicand
} //  rof
```

The first version is known as “Order n” because it loops once for each value of the multiplier. The shift and add version shown directly above is known as “Order $\log_2$” because it executes the $\log_2$ of the word size of the multiplier. For the eight bit multiplication example shown here, for the first method, up to 255 loops (and addition operations) may have to be executed. For the second example, a maximum of 8 loops (one for each bit, which is a simple way to calculate $\log_2$ of a number) is required.

The final method of multiplying two numbers together is known as “Booth’s algorithm” and looks for opportunities to reduce the number of addition operations that are required by rounding the multiplier up and then adjusting the product by subtracting the multiplier’s zero bits that were ignored. For the example given in this section (123 multiplied by 45), Booth’s algorithm would recognize that 45, B’00101101’ rounds up to 64 (B’01000000’). Multiplying a binary number by 64 is the same as shifting left six times.

To adjust the product, the basic multiplicand (multiplied by 1) along with all the instances where the multiplier has bit value of zero (in this case, bits one and four) have to be taken away from the rounded up value. For this example, the multiplication operation would look like:

$$
\begin{array}{rr}
\multicolumn{2}{l}{(\texttt{B}'\texttt{01111011}' << 6) - \texttt{B}'\texttt{01111011}' - (\texttt{B}'\texttt{01111011}' << 1)} \\
\multicolumn{2}{l}{\quad - (\texttt{B}'\texttt{01111011}' << 4)} \\
= & \texttt{B}'\texttt{01111011000000}' \\
- & \texttt{B}'\texttt{01111011}' \\
- & \texttt{B}'\texttt{011110110}' \\
- & \texttt{B}'\texttt{011110110000}' \\
\hline
 & \texttt{B}'\texttt{01010110011111}'
\end{array}
$$

which is the same result as we got above for a bit less work. Booth’s algorithm can produce a product in fewer, the same or more addition/subtraction operations as the previous method, so care must be taken to make sure that it is only used when it is going to provide an advantage.

Each of the three methods presented so far requires the ability to “loop” through multiple iterations. This is a problem for most digital electronic circuits, as it not only requires a “clock” to synchronize the operations but it will also most likely take up more time than is desired. When a digital logic multiplier is designed, it typically looks something like Fig. 5-12. This circuit is wired to add all the multiplicand bits together for each possible multiplier values.

The multiplier bits are taken into account by ANDing them with each of the multiplicand bits. If a multiplier bit is zero, then the shifted up multiplicand bits are not passed to the multi-bit adders.

There are a couple points about the multi-bit adders that you should be aware of. The first is that the maximum number of input bits for the adders used in the multiplier circuit is the number of bits in the multiplicand plus the $\log_2$ value of the multiplier. Secondly, as drawn, the adders are connected in a “ripple” configuration – a commercial circuit would probably wire the

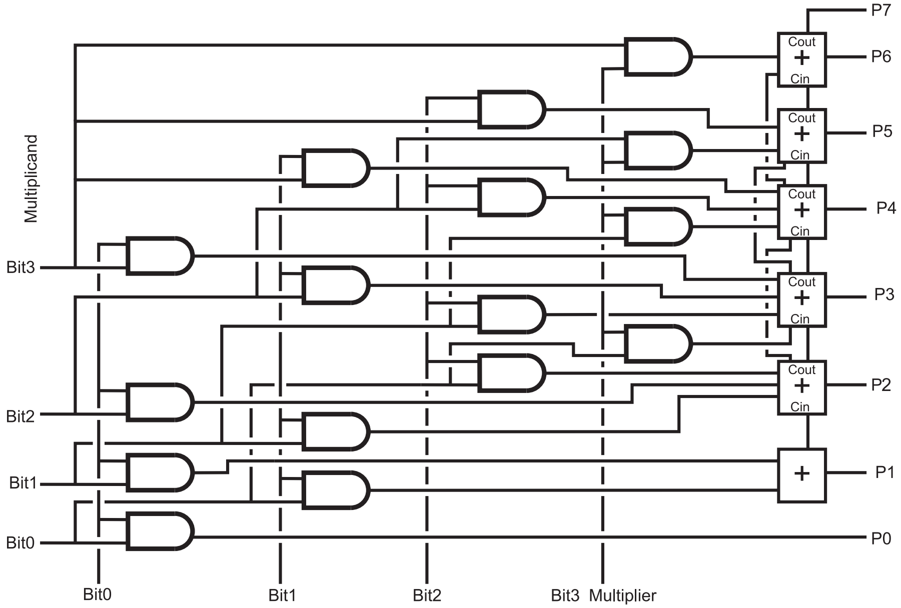

Fig. 5-12. Four bit multiplier circuit.

adders together as a carry look-ahead to minimize the time required for the multiplication operation to take place.

Before leaving the topic of multiplication, I should point out that all the methods presented here will handle multiplication of two's complement negative numbers "natively". This is to say that no additional gates must be added to support the multiplicand or multiplier being negative.

Division is significantly more difficult to implement and is very rarely implemented in low-cost devices. Handling negative values considerably complicates the division operation and in this section, as well as most commercial solutions, negative values cannot be used for the dividend or divisor. To avoid the hardware complexities of division, software intensive solutions are normally done such as a repeated subtraction:

```
Quotient = 0;                      //Clear result accumulator
while (Dividend >= Divisor)        //Repeat Subtraction
{
    Dividend = Dividend - Divisor;
    Quotient = Quotient + 1;
}  //  elihw
```

The bit shifting method shown for multiplication can also be used, but before comparisons can start, the divisor should be shifted up the word size of the dividend. To follow the bit shifting division code listed below you might want to do a thought experiment and single step through it with arbitrary values to see exactly how it works:

```
Quotient = 0;                  //Clear result accumulator
Divisor = Divisor << DividendWordSize;
DivisorPos = 1<<DivendendWordSize;
                               //Current Divisor Bit Shift
while (DivisorPos != 0)
                            //Repeat While Divisor Shifted
{
if (Dividend >= Divisor)    //Can you take away current
{
   Dividend = Dividend - Divisor;
   Quotient = Quotient + DivisorPos;
} //  fi
Divisor = Divisor >> 1;          //Shift Down Divisor
DivisorPos = DivisorPos >> 1;
} //  elihw
```

At the end of both these division algorithms, “Quotient” contains the quotient of the division operation and “Dividend” contains the remainder.

The bit shifting division algorithm could be implemented using digital electronic gates as I demonstrated for the bit shifting multiplication algorithm, but you will find that it is quite a bit more complex than the bit shifting multiplication application in Fig. 5-12. This does not mean that there are some tricks you cannot implement if a division operation is required.

For example, if you wanted to divide a value by a known, constant value, you could multiply it by its fraction of 256 (rather than the typical 1) and then divide by 256 (which is accomplished by shifting right by eight bits). For example, dividing 123 by 5 would be accomplished by multiplying 123 by 51 (256 divided by 5) and shifting the product (6,273) to the right by 8 bits to get the result 24. While this method seems like it’s complex, it is actually quite easy to implement in digital electronics.

Quiz

1. 6 − 5 is the same as:
   (a) 6 + (−5)
   (b) 5 − 6
   (c) 999999
   (d) B'1111 1111'
2. In a universe where infinity (the highest possible number) is one million (1,000,000); "−11" could be represented as:
   (a) Only −11
   (b) 999,988
   (c) 999,989
   (d) 89
3. A "half adder":
   (a) Can perform an addition operation on two bits
   (b) Can add half the bits together of an addition operation
   (c) Combines the "carry" outputs of a "full adder" to produce the correct result
   (d) Is built from half the number of gates as a full adder
4. A "ripple adder" is not used in a PC or workstation processor because:
   (a) Its complexity can affect the operation of other arithmetic functions
   (b) The result is often wrong by one or two bits
   (c) The delay required for the signal to pass through the gates can be unacceptably long
   (d) It cannot handle the 32 or 64 bit addition operations required
5. B'10' − B'01' passed through two full subtracters produces the result:
   (a) Cannot be done because a borrow operation is required
   (b) B'01' with borrow = 1
   (c) B'10' with borrow = 0
   (d) B'01' with borrow = 0
6. Converting the four bit, two's complement value "−4" to a positive number by inverting each bit and incrementing the result produces the bit pattern:
   (a) B'0100'

   (b) Which is five bits long and is invalid
   (c) B'0011'
   (d) B'1100'

7. Busses are made up of:
   (a) Multiple bits of a single value
   (b) Multiple bits passing to the same subsystem of the application
   (c) The highest speed signals in the application
   (d) Related bits

8. Multiplying two four bit numbers by repeated addition:
   (a) Will require up to 4 addition operations
   (b) Will require up to 15 addition operations
   (c) Cannot be implemented in digital electronics
   (d) Is the fastest way of performing binary multiplication

9. Multiplying a binary number by 16 can be accomplished by:
   (a) Clearing the least significant four bits
   (b) Shifting left four bits
   (c) Shifting right four bits
   (d) Setting the least significant four bits

10. Dividing an eight bit value by the constant value 6 is best accomplished by:
    (a) Using the repeated subtraction method
    (b) Using the bit shifting method
    (c) Shifting the value to the right by two and then shifting the value to the right by 1 and adding the two values.
    (d) Multiplying by 256/6 (42) and shifting the product to the right by 8 bits

6

CHAPTER

Practical Combinatorial Circuit Implementation

When you are designing your first application that is built from digital electronics, you will probably feel like you have just joined a never-ending role-playing game in which all the other players know more than you do. Later in the book, I will present some ideas on how to read a datasheet and what to look for in it, but for now, I would like to discuss a number of the options that you should be aware of and are thinking about when you first start designing your application.

Using the role-playing game analogy with digital electronics may seem to be facetious, but there are actually a lot of similarities that you should be aware of. First and foremost, each digital electronic chip that you can choose from has a number of characteristics that you will have to be aware of and

Copyright © 2005 by The McGraw-Hill Companies, Inc. Click here for terms of use.

Table 6-1 Important characteristics of a digital electronic chip.

Characteristic	Comments
Function	Gate type, chip function
# Bits	The number of bits per gate input or number of bits used by the function
# Gates/functions	What does the chip do and how many are there
Technology	Electronic standard chip is implemented
Output type	Gate output type
Dependencies	Issues to be aware of
Manufacturer	Who makes the chip/where can it be purchased

choose from when you are specifying the parts used in your application. When choosing between the parts, it might be a good idea to come up with a card, similar to the cards used in role-playing games to explain the different characters, characteristics and strengths and weaknesses. A sample card for a digital electronic device might look something like Table 6-1.

The "function" of the chip is a brief description of the gates provided by the chip or the digital logic function provided by the chip (such as an adder or a magnitude comparator). At this point in the book, you might feel that it is sufficient to specify a chip for a needed function, but the following characteristics are critical for you to understand that you need to be able to select the right chip for the right application.

When I have presented simple gates, they have all (with the exception of the NOT gate) two inputs. Along with two inputs, there are a number of different inputs for a variety of different types of gates. For example, in standard TTL, you can get NAND gates with two, three, four and eight inputs. Four and eight bit adders as well as different chips with different bit counts are also available. When selecting a chip for an application, you should be cognizant of the bit options that are available to minimize the number of chips required.

The basic TTL chips have four two input gates and six one input gates, but if the number of bits changes, then the number of gates within the chip changes (or the plastic package type and the number of pins changes). As surprising as it seems, many complex functions can have more than one built into the package. Like the number of bits, the number of functions within the chip will help you plan out how many chips you will need in the application.

So far in the book, I have really just indicated that there are two types of technology used for standard logic devices. In actuality, there are dozens and in Table 6-2, I have listed the most popular ones with their input, output and operating characteristics. For the different varieties of "TTL", "C", "AC"

Table 6-2 Digital logic technologies with electrical characteristics.

Chip type	Power supply	Gate delay	Input threshold	"0" output	"1" output	Output sink
TTL	Vcc = 4.5 to 5.5 V	8 ns	N/A	0.3 V	3.3 V	12 mA
L TTL	Vcc = 4.5 to 5.5 V	15 ns	N/A	0.3 V	3.4 V	5 mA
LS TTL	Vcc = 4.5 to 5.5 V	10 ns	N/A	0.3 V	3.4 V	8 mA
S TTL	Vcc = 4.75 to 5.25 V	5 ns	N/A	0.5 V	3.4 V	40 mA
AS TTL	Vcc = 4.5 to 5.5 V	2 ns	N/A	0.3 V	Vcc – 2 V	20 mA
ALS TTL	Vcc = 4.5 to 5.5 V	4 ns	N/A	0.3 V	Vcc – 2 V	8 mA
F TTL	Vcc = 4.5 to 5.5 V	2 ns	N/A	0.3 V	3.5 V	20 mA
C CMOS	Vcc = 3 to 15 V	50 ns	0.7 Vcc	0.1 Vcc	0.9 Vcc	3.3 mA*
AC CMOS	Vcc = 2 to 6 V	8 ns	0.7 Vcc	0.1 V	Vcc – 0.1 V	50 mA
HC/HCT	Vcc = 2 to 6 V	9 ns	0.7 Vcc	0.1 V	Vcc – 0.1 V	25 mA
4000	Vdd = 3 to 15 V	30 ns	0.5 Vdd	0.1 V	Vdd – 0.1 V	0.8 mA*

and “HC/HCT” logic families, the part number starts with “74” and for the “4000” series of CMOS chips, it has a four digit part number, starting with “4”. Table 6-2 lists the different aspects of the different types of logic chips that you will want to work with.

The “output sink” currents are specified for a power voltage of 5 volts. If you increase the power supply voltage of the indicated (with a “*”) CMOS parts, you will also increase their output current source and sink capabilities considerably.

In Table 6-2, I marked TTL input threshold voltage as “not applicable” (N/A) because, as you know, TTL is current driven rather than voltage driven. You should assume that the current drawn from the TTL input is 1 mA for a “0” or “low” input. CMOS logic is voltage driven, so the input voltage threshold specification is an appropriate parameter.

The output current source capability is not specified because many early chips were just able to sink current. This was all that was required for TTL and it allowed external devices, such as LEDs, to be driven from the logic gate’s output without any additional hardware and it simplified the design of the first MOSFET-based logic chips. The asterisk (“*”) indicates that the sink current specification is for 5 volts power; changing the power supply voltage will change the maximum current sink capability as well.

There are three basic output types: totem pole, open collector and the tri-state driver (which is presented later in this chapter). In cases where multiple outputs are combined, different output types should *never* be combined due to possible bus contention.

Virtually all of the electrical dependencies that you should be aware of are listed in Table 6-2, but you may have a number of operating dependencies (such as making sure CMOS inputs are tied high or low) or physical design issues that you should be aware of. “Physical design” is the process of designing a printed circuit board with internal connections built into it that have the chips soldered onto it. The primary chip dependencies that you should be aware of when designing a printed circuit board are the location and type of the chip’s pins as well as any heat removal (i.e. heat sinks) requirements that the chip may have.

Finally, you should know who makes the part and where you can purchase it. This point is often overlooked, but you will find many manufacturers that advertise parts that are seemingly designed just for your application. The first problem that you encounter is that your company has a policy of only buying parts that are available from multiple sources or you may discover that the manufacturer is not considered to be reliable and production quantity parts are difficult to come by. For your first designs, it is a good rule to only use parts that are easily obtainable and, ideally, built by multiple sources.

This may make the design operation a bit more difficult and the final product larger than it could have been, but chances are the product will go through manufacturing very smoothly and with few difficult ‘‘hiccups’’.

Race Conditions and Timing Analysis

As you begin to create digital electronic circuits that are more and more complex and run faster and faster, you are going to discover that they are going to stop working or they are going to start working unpredictably. In trying to find the problem, you will probably look at different parts of the circuit, ranging from the power supply to the wiring and maybe rebuilding it several times to see if it is being affected by other electrical devices running near the application. At some point you will give up and build as well as redesign the circuit, only to discover that the problem is still there.

So what’s the problem? Chances are you have encountered a ‘‘race condition’’, which is normally defined as ‘‘A condition in digital electronics where two or more signals do not always arrive in the same order.’’ Personally, I use a slightly different definition for race condition which states that ‘‘A race condition occurs in any digital electronic circuit where the output to input response time changes according to the inputs passed to it.’’ My definition is a bit more specific and should give you some ideas on where to look for the problem.

Simply put, a race condition is a case where an expected event does not occur.

To illustrate the issue, assume that the application consists of a circuit that is designed to respond to an internal value at a specific time. If the digital electronics used to produce this internal value does not always complete within the specified time, what happens in the circuit that uses this value for input? Chances are the circuit will respond incorrectly, resulting in the problem that you are trying to debug.

An example circuit that has the capability of producing a race condition is shown in Fig. 6-1.

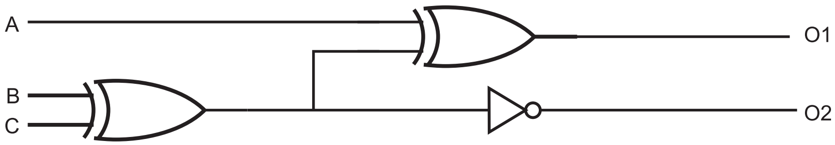

Fig. 6-1. Example race condition circuit.

Figure 6-2 is the waveform output of this circuit to a three bit incrementing signal and, in it, I have indicated the output bits (“O1” and “O2”) and indicated where the operation of the circuit is “correct” (O2 is valid after O1) as well as a possible race condition (when O1 is valid after O2). I have also indicated times, using a shaded block, when both of the XOR inputs are changing and there could be a “glitch” caused by both inputs changing state simultaneously, at which time the output of the XOR gate is unknown.

The glitch produced by the XOR gate is an excellent example of a race condition. As I presented earlier in the book, the XOR gate is typically made up of five NAND gates in the configuration shown in Fig. 6-3. If one input changes, then the output will change state to either “1” or “0” without any glitches, but what happens when the two inputs change state simultaneously?

Quickly thinking about it, you might think that the output doesn’t change state, but consider what happens at the NAND gate level of the XOR gate.

Fig. 6-3. XOR gate TTL implementation.

Table 6.3 XOR gate input change study.

Gate delay	Input "A"	Input "B"	G1	G2	G3	G4	Output
–1	1	0	0	1	1	0	1
0	0	1	0	1	1	0	1
1	0	1	1	0	1	1	0
2	0	1	1	0	0	1	1

Table 6-3 lists the NAND gate outputs for the different gates as I've marked them in Fig. 6-3. To help illustrate what's happening, I use ‘‘gate delays’’ as the time increments of this study. In Table 6-3, the initial conditions are one gate delay before the two inputs change value. The inputs change value at gate delay ‘‘0’’.

According to this study, at gate delay 1, the output will be a ‘‘0’’ because the direct inputs from A and B to G3 and G4 have changed at gate delay 0, *but* the inverted inputs from G1 and G2 have not. It won't be until gate delay 2 that the inputs to NAND gates G3 and G4 have stabilized. Thus, the time from gate delay 1 to gate delay 2 will result in generally unknown logic levels, which are normally characterized by the term ‘‘glitch’’.

Going back to Fig. 6-2, you can probably observe what I mean by the race condition, but I'm sure it seems very subtle. Actually, this is the point that I want to make: race conditions are very subtle and are very difficult to observe. For this section, I spent quite a bit of time with a 74C85 (quad XOR gate), a PIC16F627A (Microchip PIC Microcontroller to produce the ‘‘A’’, ‘‘B’’ and ‘‘C’’ inputs to the circuit) and an oscilloscope trying to capture the events shown in Fig. 6-2. I gave up after about 5 hours of trying to capture the event on the oscilloscope in a way that it would be easily seen.

Race conditions are dependent on part mix, applied voltage and ambient conditions. You may find some sample circuits which never have the problem while others will never seem to work right. Finding the actual event is extremely difficult and only after doing a thorough timing analysis of the circuit will you find the opportunity for a race condition to occur. The prevention for this problem is quite simple – figure out what your worst case gate delay is through the circuit and only sample data after this time (even add a 10% margin to make sure there is no chance of marginal components causing problems).

Avoiding the opportunity is why chip designers work at making sure multiple outputs are active at the same time for changing inputs. Looking at the ‘‘A’’/‘‘B’’/‘‘C’’ waveform of Fig. 6-2, you might have thought that it is impossible to achieve the signals at precisely the same time, but it is very likely that if a single gate is producing incrementing outputs, the ‘‘edge’’ of each output bit will be precisely aligned with each other and will cause the glitch on the output of the XOR gate.

The process of determining what is the worst case gate delay is the same process I used for finding the ‘‘glitch’’ in the XOR gate and is known as ‘‘timing analysis’’. It is unusual for somebody to work through this analysis by hand as I have done, except for very simple circuits. When timing analysis is done on a commercial product, it is normally done using a logic simulator, which can find the longest delays and report on any problems.

Quick and Dirty Logic Gates

One of the most frustrating aspects of designing digital electronic circuits is that when you are almost finished, you often discover that you are a gate or two short and you are left with the question of whether or not you should add another chip to the circuit. The major problem with adding another chip to the circuit is the requirement for additional space to place the chip in the circuit. Along with the need for additional space, adding another chip will add to the costs of the application and the difficulty in assembling it. In Chapter 2, I discussed that by using the Boolean arithmetic laws and rules, you could produce various functions using different gates than the ones that are ‘‘best suited’’ for the requirements. In the cases where there are no leftover gates available, a gate can be ‘‘cobbled’’ together with a few resistors, diodes and maybe a transistor. These simple gates are often referred to as being ‘‘MML’’ or ‘‘Mickey Mouse logic’’ technology because they can generally be used in most situations and with different logic families when a quick and dirty solution is required.

To be used successfully, they must be matched to the inputs and outputs of the different logic families that you are using and should not result in long switching times, which will affect the operation of the application, or large current draws, which could damage other components. As a rule of thumb, do not use one of the simple gates presented here between differing

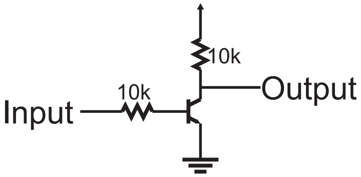

Fig. 6-4. RTL inverter.

technology gates; you will find that operation of different technologies can often be incompatible when you are adding resistors, diodes and transistors like the ones used in the sample gates presented here. Another rule of thumb is to make sure that each MML gate only drives one input – you can get into trouble with input fan-outs and multiple gate current sinking requirements very quickly. Along with trying to satisfy these requirements, there are cases where you will find that the MML gate will require at least as many pins as adding another chip and will be more difficult to wire. Generally speaking, adding MML gates to your application should be considered a ‘‘last’’ resort, not something you design in right from the start.

The most basic MML gate is the ‘‘inverter’’ and should not be a surprise. Figure 6-4 shows the circuit for the MML inverter, built out of two 10 k resistors and an NPN transistor. This inverter is actually a basic ‘‘RTL’’ (resistor–transistor logic) technology device and outputs a high voltage, when it is not being driven by any current. When current is passed to the gate, the transistor turns on and the output is pulled to ground (with good current sinking capability).

This circuit (as well as the other MML gates I discuss in this section) cannot handle high voltage or current inputs and outputs as well as commercially available logic gates and need to be ‘‘buffered’’. The need for buffering the MML’s gate inputs and output is an important point to note when considering using an MML gate in an application. As a rule, MML gates must be placed in the middle of a logic ‘‘string’’ rather than at the input or output ends to ensure that if you are expecting certain characteristics (such as the ability to drive a LED), standard TTL or CMOS technology gates will provide you with it.

The inverter circuit can be simply modified by adding another transistor and resistor, as shown in Fig. 6-5, to create an RTL NOR gate. The RTL NAND gate is shown in Fig. 6-6. The NOR gate is considered the basis of RTL technology.

Implementing an AND or OR gate in MML is a bit more complex and requires a good understanding of the input/output parameters

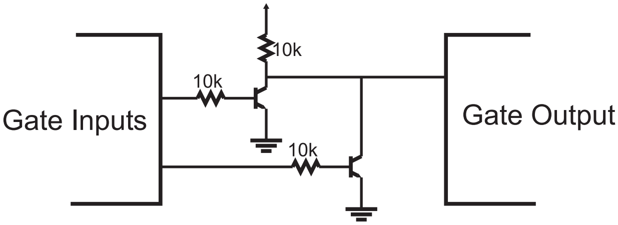

Fig. 6-5. RTL NOR gate.

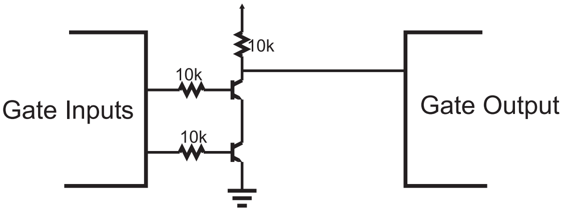

Fig. 6-6. RTL NAND gate.

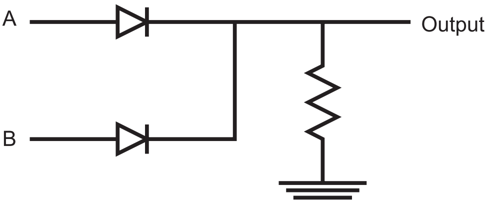

Fig. 6-7. MML OR gate.

of the logic families. In Fig. 6-7, I have shown a sample design for an OR using two diodes and a resistor. The use of a 470 ohm resistor is probably surprising, but it was chosen to allow the gate to be used with both CMOS and TTL logic. In this case, if neither input has a high voltage, then the output will pull the input to ground. If the input is a CMOS gate, then the input will behave as if it were tied to ground. The 470 ohm resistor will allow the TTL input current to pass through ground and it will behave as if the input was at a low logic level. When the resistor is connected to a CMOS input, it will be effectively tying the input to ground, even though no current is flowing through it. In either case, when one of the inputs is driven high, the input pin will be held high and the gate connected to the output of the OR gate will behave as if a high logic level was applied to it.

An MML AND gate (Fig. 6-8) is the simplest in terms of the number of components. The diode and resistor work together to provide a high voltage

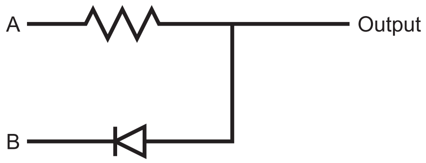

Fig. 6-8. MML AND gate.

when both inputs are high, but when one of them is pulled low, the voltage level will be pulled down and current drawn from the input gate it is connected to.

While the MML AND presented in Fig. 6-8 will work in virtually any application, you may find that you will want to use a 470 ohm resistor in the circuit and a 10 k one in CMOS logic applications. The reason for doing this is to minimize the current drawn by the application; with a 470 ohm resistor, roughly 10 mA will be drawn when the output of the gate is low. This current draw decreases to 100 µA when a 10 k resistor is used instead for the resistors in these two gates.

Dotted AND and Tri-State Logic Drivers

You may feel constrained by the rule that you can only have one driver on a single line (or net). In Chapter 3, I introduced you to the concept of the "dotted AND" bus in which there was a common pull up on the net along with a number of transistor switches, each one of which could "pull" the net to a low voltage/logic level (and draw the current from any TTL gates inputs connected to the dotted AND). The dotted AND works reasonably well and has the advantage that it can control output voltages greater than the power applied to the logic chips. Some more subtle advantages are that more than one output can be active (tying the net to ground) and the operation of the bus will not be affected and TTL open collector and CMOS logic open drain outputs can be placed on the bus along with mechanical switches and other devices which can pull the bus to ground.

The dotted AND bus's main disadvantage is its inability to source significant amounts of current. Smaller value pull up resistors can be used, but this increases the amount of current passed to ground when one of the open collector transistors is on. The dotted AND can be considered to be quite inefficient if it is low for a long period of time, because it is passing current directly to ground. The inability to source large amounts of current

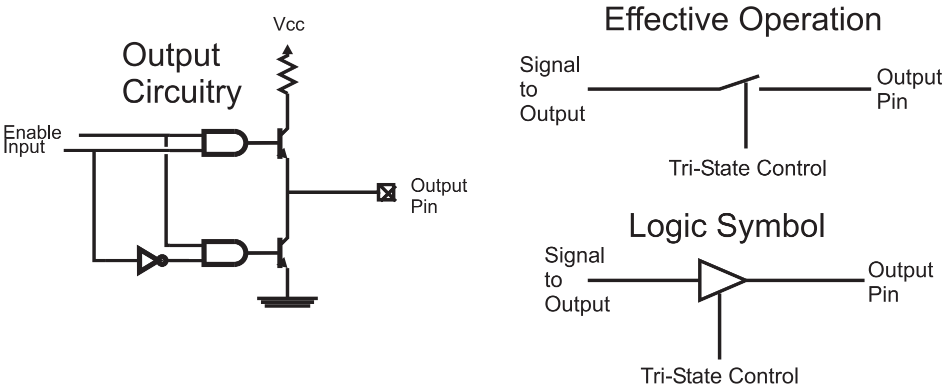

Fig. 6-9. Tri-state driver circuit diagram and operation.

is a drawback when high-speed signals are involved is the major disadvantage of the dotted AND bus. Changing an input from a high to a low, especially when there are some relatively large capacitances on the net, the switching time can become unreasonably slow.

A common error made by new circuit designers when they are adding a dotted AND bus to their designs is forgetting to add the pull up resistor. If the resistor has been forgotten, then the bus will never have a ‘‘high’’ voltage (although it will have a ‘‘low’’ voltage that can be detected). You will find that TTL inputs connected to a dotted AND but not having a pull up will work correctly, but CMOS logic inputs will not.

Another solution to the problem of wanting to have multiple drivers on the same net is to use ‘‘tri-state’’ drivers (Fig. 6-9). These drivers can ‘‘turn off’’ the transistors as effectively as if a switch were opened (the diagram marked ‘‘Effective Operation’’ in Fig. 6-9).

The left-hand side of circuit diagram of Fig. 6-9 shows how the tri-state driver works. If the tri-state control bit is inactive, the outputs of the two AND gates will always be low and the NPN output transistors can never be turned on. This ‘‘inactive’’ state is also known as the ‘‘high impedance state’’. When the tri-state control bit is active, then a high to either the top or bottom NPN transistor will allow the output to behave as an ordinary TTL output.

This ability to ‘‘turn off’’ allows multiple drivers, such as I have shown in Fig. 6-10, to be wired together. In this case, if data was to be placed on the net from Driver ‘‘B’’, the ‘‘Ctrl A’’ line would become inactive (the ‘‘high impedance state’’), followed by the ‘‘Ctrl B’’ line becoming active. At this point, the bus would be driven with the data coming from Driver ‘‘B’’.

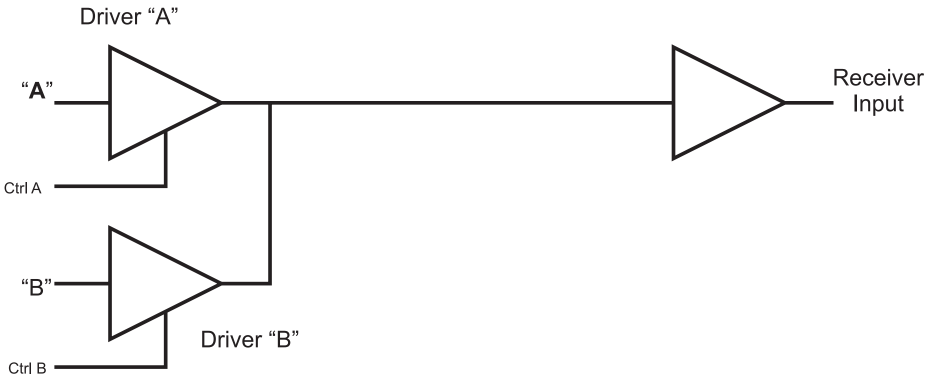

Fig. 6-10. Multiple tri-state drivers on a single net.

It is important that only one tri-state driver is active at one time because the voltage on the common net will be indeterminate, as will be the logic level. You may be thinking that the term ''indeterminate'' to be the case when two drivers are active and are attempting to drive the net at different levels. This is true, but it is often also the case if two different drivers are driving at the same level: CMOS logic and TTL drivers will attempt to drive the net to different voltage levels and even TTL will not give repeating answers when you are trying to understand what is happening. The technical term for the situation where two tri-state drivers are active at the same time is ''bus contention'' and it should be avoided at all costs – only one driver should be active on the net at any one time.

At the start of this section, I noted that there could be more than one output active on a net at the same time. Note that when I say ''multiple active outputs'', I mean more than one driver pulling the net low. I do not recommend this to be part of the design, however; multiple active outputs are impossible to differentiate and you will have problems figuring out which bits are active and what signal is being sent (with multiple outputs active, state changes from one output will most likely be masked by the active operation of others).

Before leaving this section, I do want to point out that tri-state drivers *can* be used on a dotted AND bus. This is probably surprising, considering the dire warnings I have put in regarding bus contention. The trick to adding a tri-state driver to a dotted AND bus is that it is normally disabled and only a low voltage can be put on the net by the tri-state driver. High values are output by simply disabling the tri-state driver and letting the net's pull up provide the high voltage.

Combining Functions on a Net

As a purely intellectual exercise, it can be interesting to see how many functions you can build into a single digital electronics net. From a practical point of view, cramming multiple functions on a single line will minimize the amount of effort that must be expended to build a prototype application. Many products carry out multiple functions on a single line; generally, this is done to allow the manufacture and sale of simpler products. Whatever the motivation, ''stretching'' a logic technology to allow multiple functions on a single net requires a strong knowledge of the technology's electrical parameters and the technology's normal operating conditions. The most important thing to remember is that the input/output devices attached to the net must be properly coordinated to make sure that data is read and written at the right times.

The most obvious ways of connecting two drivers together is to use dotted AND and tri-state drivers on a ''bus'', as I discussed in the previous section. These methods work well and should be considered as the primary method of implementing multiple devices on the net. The other methods discussed here work best for specific situations; but there is no reason why you can't modify your design to take advantage of these specific instances.

When interfacing the bi-directional digital I/O pin to a CMOS driver and a CMOS receiver (such as a memory with separate output and input pins), a resistor can be used to avoid bus contention at any of the pins, as is shown in Fig. 6-11.

Using this wiring, when the bi-directional I/O pin is driving an output, it will be driving the ''Data In'' pin register, regardless of the output of the ''Data Out'' pin. If the bi-directional and ''Data Out'' pins are driving different logic levels, the resistor will limit the current flowing between the bi-directional and the memory ''Data Out'' pin. The value received on the ''Data In'' pin will be the bi-directional device's output.

When the bi-directional digital I/O is receiving data from the memory, the I/O pin will be put in ''input'' (or ''high impedance'') mode and the

Data I/O

Fig. 6-12. Adding a button to a CMOS bidirectional net.

“Data Out” pin will drive its value to not only the bi-directional device’s I/O pin, but the “Data In” pin, as I noted above. In this situation, the “Data In” pin should not be latching any data in; the simplest way to ensure this is to make the digital I/O pin part of the I/O control circuitry. This is an important point because it defines how this circuit works. A common use for this method of connection data in and data out pins is used in memory chips that have separate data input and output pins.

User buttons can be placed on the same net as logic signals as Fig. 6-12 shows.

When the button is open or closed, the bi-directional logic device can drive data to the input device, the 100 k and 10 k resistors will limit the current flow between Vcc and ground. If the bi-directional logic device is going to read the button “high” (switch open) or “low” (switch closed) it will be driven on the bus at low currents when the pin is in “Input Mode”. If the button switch is open, then the 100 k resistor acts like a “pull up” and a “1” is returned. When the button switch is closed, there will be approximately a half volt across the 10 k resistor, which will be read as a “0”.

The button with the two resistors tying the circuit to power and ground is like a low-current driver and the voltage produced is easily “overpowered” by active drivers. Like the first method, the external input device cannot receive data except when the bi-directional device is driving the circuit. A separate clock or enable should be used to ensure that input data is received when the bi-directional device is driving the line.

This method of adding a button to a net can be extrapolated to work with a switch matrix keyboard (presented later in the book), although the circuit and interface operation will become quite complex. Secondly, a resistor/capacitor network for “debouncing” the button cannot be used with this circuit as it will “slow down” the response of the bi-directional device driving the data input pin and will cause problems with the correct value being accepted.

For both of these methods of providing multiple features to a single net, you should only use CMOS logic as it is voltage controlled and not current controlled, like TTL. You *may* be able to use TTL drivers with these circuits, but they may be unreliable. To avoid problems with invalid currents being available to TTL receivers, just use the latter two circuits with CMOS digital logic.

Designing a circuit in which multiple functions are provided on a single net for an application is not always possible or even desirable. Like any design feature implemented in an application, before trying to combine multiple functions on a single net, you should understand the benefits as well as the costs. When it is possible, you can see some pretty spectacular results; my personal record was for a LCD driver in which I was able to combine five functions on a single net – LCD Data Write, LCD Data Read, Data In Strobe, Data Ready Poll and configuration switch poll.

Quiz

1. What parameter is not listed in the chip characteristic card?
   (a) Input fanout
   (b) Number of gates built into the chip
   (c) Electrical dependencies
   (d) Maximum operating speed
2. What is not a typical digital electronic output pin type?
   (a) Totem pole
   (b) Open collector
   (c) High-current
   (d) Tri-state driver
3. Other than the XOR gate, are any other of the six basic I/O gates capable of producing race conditions just by themselves?
   (a) Each one is capable of producing a race condition under certain circumstances
   (b) The NOR Gate in TTL
   (c) The AND Gate in CMOS Logic
   (d) No

4. What is not a factor in determining if a marginal circuit and component will produce a race condition?
   (a) Ambient temperature
   (b) Net length
   (c) Power voltage
   (d) The phases of the moon

5. Mickey Mouse logic should be used:
   (a) Never
   (b) When you are in a hurry to get the application finished
   (c) When you have board space, cost and available gate constraints that preclude adding a standard chip
   (d) When there is a need to pass a CMOS output to a TTL input

6. Each item is an advantage of a dotted AND bus except:
   (a) The dotted AND bus can have tri-state drivers on it as well as mechanical switches
   (b) The dotted AND bus can control voltages greater than the chip's Vdd/Vss
   (c) The dotted AND bus is cheaper than one manufactured with tri-state drivers
   (d) The dotted AND bus can consist of CMOS logic as well as TTL drivers

7. When tri-state drivers are inactive, another term that is used to describe the state is:
   (a) High resistance
   (b) High impedance
   (c) Low current output
   (d) Driver isolation

8. When should multiple tri-state drivers be active?
   (a) When more current is required on the net
   (b) When more speed is required on the net
   (c) When the receiver detects an ambiguous logic level
   (d) Never

9. When adding a push button to a net, can the 100 k resistor connected to positive power and the 10 k resistor connected to positive power be swapped?
   (a) Yes
   (b) No

(c) Only if TTL receivers and drivers are used.
(d) Yes, if you can ensure that the signals passing between the digital devices are still within specified operating margins.

10. When putting a receiver and driver on the same net, can the current limiting resistor be wired between the bi-directional logic device and the "Data In" pin, leaving a direct connection between the bi-directional logic device and "Data Out"?
(a) Yes. There aren't any cases where it wouldn't work
(b) Yes, if the resistor value is within 1 k and 10 k
(c) Yes, for certain technologies of CMOS logic
(d) No. This will cause bus contention

7

CHAPTER

Feedback and Sequential Circuits

This chapter's title probably seems like a bit of a misnomer; you are probably wondering what feedback has to do with digital electronics? When I use the term "feedback", I am using it in the most literal sense, past state data are used to maintain current state data. These circuits built from the theory that I am going to provide in this chapter are commonly known as "memory devices". For digital electronic circuits to store information, that information will continually move through the circuit and is used to determine what the future value of the circuit is. Feedback is critical to provide digital electronics with the ability to "remember" previous states and data.

When you first hear the term "feedback", you probably think of an amplifier with its microphone input brought close to its speaker output (Fig. 7-1). You also probably involuntarily wince at the thought of the term "feedback" because it brings back the memory of the horrible sound the amplifier made when the microphone was too close. This type of feedback

cannot save information; the uncontrolled amplification of the signal distorts and destroys information in a very short order.

When I introduced combinatorial circuits at the start of the book, I noted that an important part of combinatorial circuits was that data could only travel in one path; no outputs were passed back to earlier inputs in a logic chain, like the one shown in Fig. 7-2. The reason for specifying that outputs were not to be passed to inputs was to make sure that an inadvertent oscillator, known as a ‘‘ring oscillator’’ (Fig. 7-3), was not created.

You should know that the inverter in Fig. 7-3 is going to invert its input. The problem arises when the input is tied to the output, as it is in this case. When the input is passed to the inverter, it outputs the inverted value, which is then immediately passed back to the input and the gate inverts the value again, and again, and so on.

Fig. 7-4. Single switch debounce circuit.

The ring oscillator is probably the simplest oscillator that you can build and the period of the oscillation runs at literally the speed of the technology's gate delay times the number of gate delays. If the ring oscillator shown in Fig. 7-3 was built from TTL (which has a gate delay of 8 ns) you would see a "square wave" with a period of 62.5 MHz. One of the functions that ring oscillators perform is the measurement of a logic technology's gate delay.

Extrapolating from what has been discussed here, you could build a simple memory circuit using the two inverters and a double throw switch, wired as shown in Fig. 7-4. This circuit is used to "debounce" a switch input. As I will discuss in later chapters, when a mechanical switch is thrown, the physical contacts within the switch literally bounce against each other before a hard, stable contact is made. This bouncing can cause quite a bit of grief when you are trying to respond to a single switch movement.

The circuit in Fig. 7-4 will pass a signal continuously between the two inverters (the output of the two inverters is the same as the input, so there is no chance for a ring oscillator) until the switch comes in contact with a connection that forces the state to change. If the switch was originally at the ground position, the signal coming from the inverter to its left would be a "0". When the switch was moved to the "Vcc" position, the signal going to the inverter to the right would be changed and its output would change.

The beauty of this circuit is that when the switch is in between contacts, the output state of the circuit remains constant.

When the switch is not touching either contact, the two inverters are maintaining the previous bit value and the circuit behaves essentially as a memory device.

There is a downside to the button debounce circuit in Fig. 7-4 and that is when the switch is thrown, it connects the left inverter output to the opposite power supply that it is driving out. This is known as ‘‘backdriving’’ and it should always be avoided.

Backdriving a gate will shorten its life in the best case and could burn it out in very short order. As noted in Fig. 7-4, you should only use CMOS inverters (which are voltage, rather than current controlled) and place the 10 k resistor between the switch and the output of the left inverter. By using this circuit, there will be no chance that the left inverter's output is tied directly to power or ground (which will be the opposite value that it's at) and the 10 k resistor will limit the amount of current that is passed. I did not put the resistor into Fig. 7-4 as it is a basic circuit that I have seen in a number of references and I wanted to point out that it does backdrive a gate output and there are ways of avoiding this problem.

The other term used in this chapter's title, ‘‘sequential circuits’’, is used to identify the class of digital electronic circuits that have memory devices within them and use their data, along with combinatorial circuits, to produce applications. A digital clock (Fig. 7-5) is an excellent example of a sequential circuit. The data output from the memory circuits of the clock are passed to

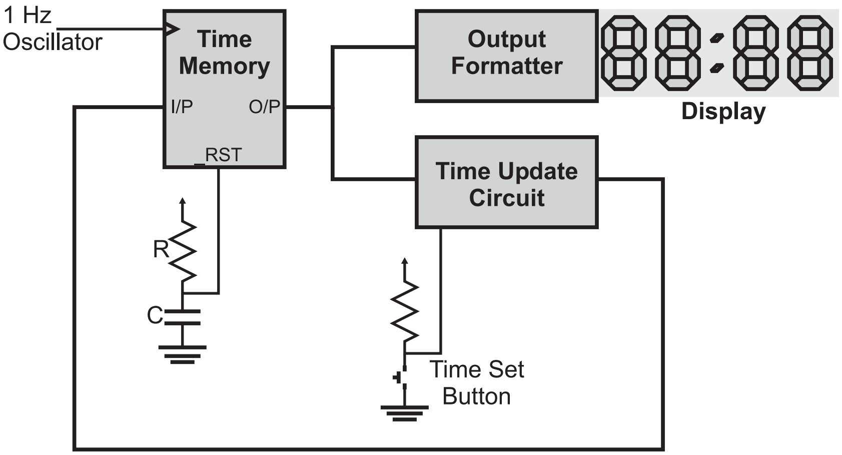

Fig. 7-5. Digital clock circuit.

combinatorial logic circuits and the outputs of the combinatorial circuits are passed back to the inputs of the ‘‘time memory’’ circuits.

Any time memory circuits, like the ones presented in this chapter, are used in a digital electronics application, the circuit is called a ‘‘sequential circuit’’.

Flip Flops (RS and JK)

The best analogy I can find for a simple, one bit ‘‘memory device’’ is the two coiled relay of Fig. 7-6. The relay coil does not have a return spring that only one coil pulls against; when the relay’s wiper is placed in a position it stays there. This memory device is set to one of two states, depending on which relay coil was last energized, pulling the wiper contact into connection with it. Once electricity to the coil is stopped, the memory device will stay in this state until the other coil is energized and the wiper is pulled towards it. This device works very similarly to the most basic electronic memory device that you will work with, the ‘‘reset-set’’ (RS) ‘‘flip flop’’.

The term ‘‘flip flop’’ is indicative of the operation of the memory device: it is either ‘‘flipped’’ to one value or ‘‘flopped’’ to another. Where the relay device relies on friction to keep the saved value constant, the electronic memory unit takes advantage of feedback to store the value. Digital feedback can only be one of two values, so its use in circuits probably seems like it is much more limited than that of analog feedback. This is true, except when it is used as a method to store a result in a circuit like the ‘‘NOR flip flop’’, shown in Fig. 7-7. Normally, the two inputs are at low voltage levels, except to change its state, in which case one of the inputs is raised to a high logic level.

If you are looking at this circuit for the first time, then it probably seems like an improbable device, one that will potentially oscillate because if the output value of one gate is passed to the other and that output is passed to

Fig. 7-8. RS flip flop state changes.

the original, it seems logical that a changing value will loop between the two gates. Fortunately, this is not the case; instead, once a value is placed in this circuit, it will stay there until it is changed or power to the circuit is taken away. Figure 7-8 shows how by raising one pin at a time, the output values of the two NOR gates are changed.

When the "R" and "S" inputs to their respective NOR gates are low, there is only one signal left that will affect the output of the NOR gates and that is output of the other NOR gate. When "Q" is low, then a low voltage will be passed to the other NOR gate. The other NOR gate outputs a high voltage because its other input is low. This high signal is passed to the original

NOR gate and causes it to output a low voltage level, which is passed to the other NOR gate and so on. . . .

The outputs of the flip flop are labeled as “Q” and “_Q”. “Q” is the positive output while “_Q” is the negative value of “Q” – exactly the same as if it were passed through an inverter. The underscore character (“_”) in front of the output label (“Q”) indicates that the signal is inverted (the same as if an exclamation mark (“!”) is used for an inverter’s output). When you look at some chip diagrams, you will see some inputs and outputs that have the underscore before or on the line above the pin label.

The “R” and “S” input pins of the flip flop are known as the “reset” and “set” pins, respectively. When the “R” input is driven high the “Q” output will be low and when “S” is high the “Q” output will be driven high. These values for “Q” will be saved when “R” and “S” are returned to the normal low voltage levels. “Q_0” and “$\_Q_0$” are the conventional shorthand to indicate the previous values for the two bits and indicates that the current values of “Q” and “_Q” are the same as the previous values. Truth tables are often used to describe the operation of flip flops and the truth table for the NOR RS flip flop is given in Table 7-1.

In Table 7-1, I have marked that if both “R” and “S” were high, while the outputs are both low, the inputs were invalid. The reason why they are considered invalid is because of what happens when R and S are driven low. If one line is driven slower than the other, then the flip flop will store its state. If both R and S are driven low at exactly the same time (not a trivial feat), then the flip flop will be in a “metastable” state, Q being neither high nor low, but anything that disturbs this balance will cause the flip flop to change to that state. The metastable state, while seemingly useless and undesirable is actually very effective as a “charge amplifier” – it can be used to detect very

small charges in capacitors. This is an important mode of operation that is taken advantage of for DRAM and SDRAM memories.

Along with building a flip flop out of NOR gates, you can also build one out of NAND gates (Fig. 7-9). This circuit works similarly to the NOR gate, except that its metastable state occurs when both inputs are low, and the inputs are active at low voltage levels, as I have shown in Table 7-2, which is the NAND RS flip flop's truth table.

You can build your own NOR RS flip flop, which has its state set by two switches as I show in Fig. 7-10 and is wired according to Fig. 7-11. I suggest that you test out the circuit in as many different ways as possible – especially investigating the metastable and post-metastable states. Unless you were to wire the R and S inputs to one switch, you will find it impossible to achieve the metastable state. The parts that are needed to build the RS flip flop are listed in Table 7-3.

Before going on, there is one additional point about flip flops that may not be immediately obvious but will be something that you will have to consider

in your career as a designer of digital electronic devices; when power is removed, the flip flops will lose the bit information contained within them. The term used to describe this phenomena is ‘‘volatility’’; flip flops are considered ‘‘volatile’’ devices. Flash memory (like the flash used in your PC) does not lose its information when power is shut off and is known as ‘‘non-volatile’’ memory.

Edge Triggered Flip Flops

The RS flip flop is useful for many ad hoc types of sequential circuits in which the flip flop state is changed asynchronously (or whenever the appropriate inputs are active). For most advanced sequential circuits (like a microprocessor), the RS flip flop is a challenge to work with and is very rarely used. Instead, most circuits use an "edge triggered" flip flop which only stores a bit when it is required. You will probably discover the edge triggered flip flop (which may also be known as a "clocked latch") to be very useful in your own applications and easier to design with than a simple RS flip flop.

The most basic type of edge triggered flip flop is the "JK" (Fig. 7-12), which provides a similar function to the RS flip flop except that it changes state when the "clock" input is "rising" (changing from "0" to "1"), as shown in the waveform diagram of Fig. 7-13.

There are a few points about Fig. 7-13 that should be discussed. I have assumed that in the initial state for this example, the output value "Q" is "1". When the first rising edge of the clock ("Clk") is encountered, both J and K are 1, so Q "toggles" or changes state. Next, when the rising edge of the clock is encountered, J is 1 and $K = 0$, so Q becomes 1 and the opposite is true for the next rising edge. In the final rising edge, both J and K are 0 and the value of Q remains the same. There is no metastable state for the JK flip flop. The operation of the JK flip flop is outlined in Table 7-4.

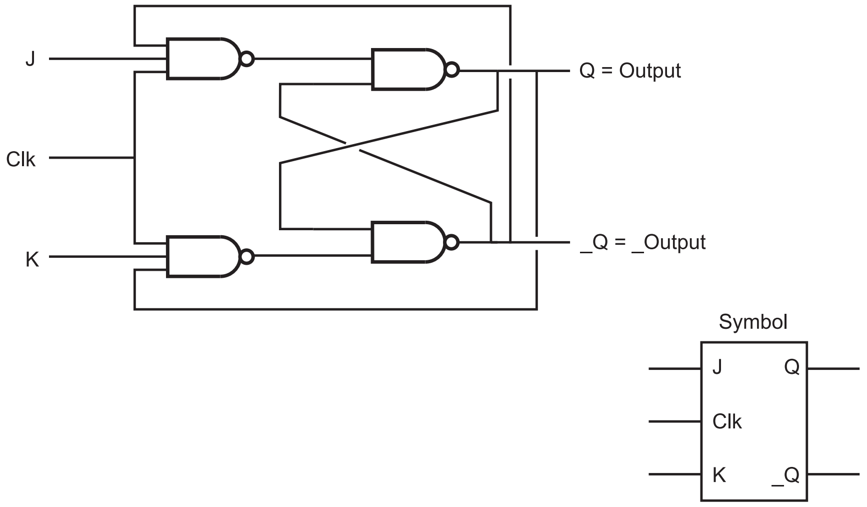

Fig. 7-12. Edge triggered JK flip flop.

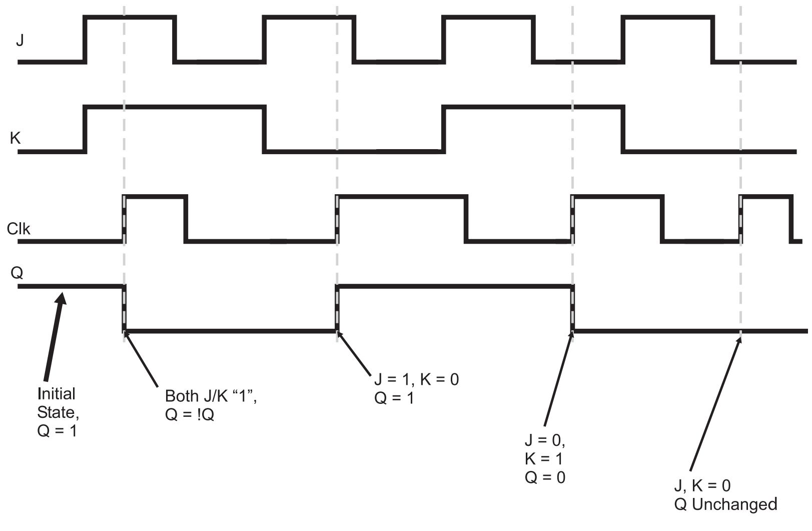

Fig. 7-13. Edge triggered JK flip flop operating waveform.

Just as a small circle on an input or an output of a logic gate indicates that the value is inverted, the clock pin on some chip diagrams is indicated by a small triangle. This convention helps minimize the clutter present in a logic diagram.

The JK flip flop is useful in general digital electronics applications, but it does not provide the necessary function for a computer register. Ideally,

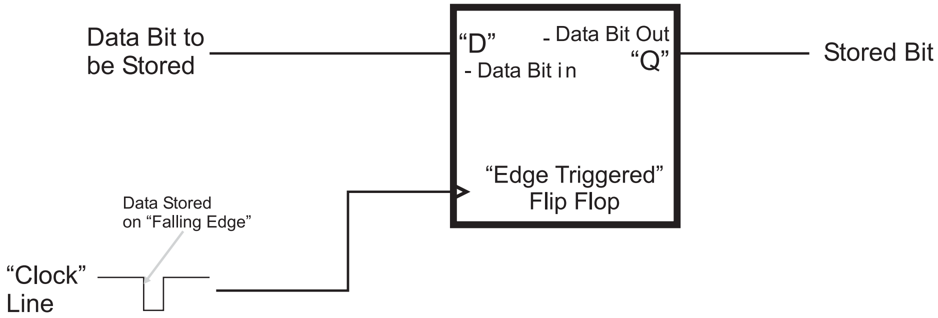

Fig. 7-14. "D" flip flop.

a clocked register's block diagram is quite simple (Fig. 7-14), consisting of a data line passed to the flip flop along with a "clock" line. While the data line stays constant, the contents of the flip flop doesn't change. When the clock line goes from high to low, the data is stored in the flip flop – this is known as a "falling edge clocked flip flop" or a "falling edge clocked register" and it is probably the most common type of flip flop that you will work with.

The edge triggered flip flop (Fig. 7-15) is based on the RS flip flop. Instead of always calling this circuit a "falling edge triggered flip flop" or "clocked register", this circuit is normally known as a "D flip flop". The organization of the flip flops used in this circuit may seem complex, but their operation is actually quite simple: the two "input" flip flops "condition" the clock and data lines and only pass a changing signal when the clock is falling, as I show in Fig. 7-16. To try and make it easier for you to understand, I have marked the outputs of the RS flip flops in Fig. 7-15 and showed the waveforms at these points.

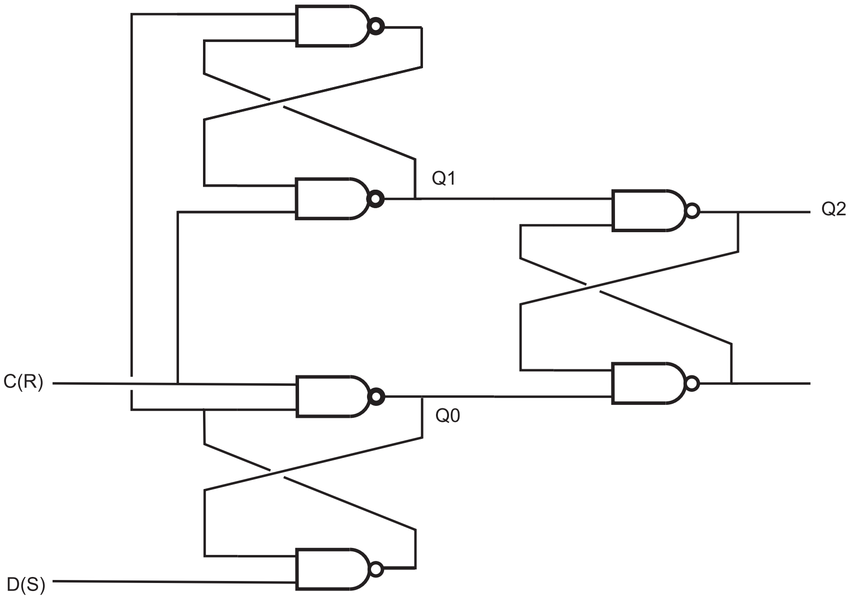

Fig. 7-15. D flip flop logic diagram.

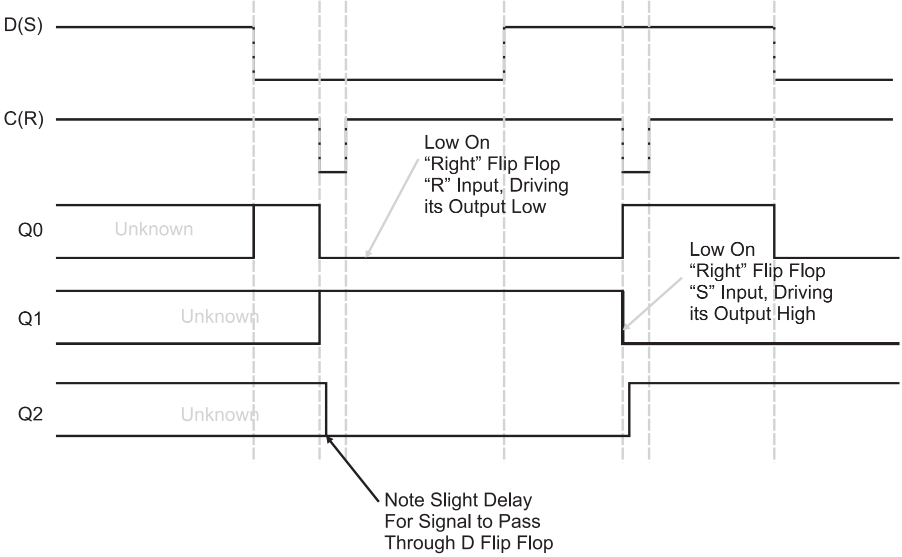

Fig. 7-16. D flip flop operating waveform.

Note that in Fig. 7-16, I have marked the flip flop states *before* the first clock pulse as being ‘‘unknown’’ (in Fig. 7-14, the initial state was assumed). This is actually a very important point and one that you will have to keep in mind when you are designing your own circuits. You cannot expect a flip flop to be at a specific state unless it is set there by some kind of ‘‘reset’’ circuit (which is discussed in the next section). The output of the edge triggered flip flop stays ‘‘unknown’’ until some value is written in it. If you look at the signals being passed to the right flip flop (Output Q0), you will see that the inputs are unknown until the ‘‘data’’ line becomes low, at which point the two inputs to the right flip flop become high and the ‘‘unknown’’ bit value is stored properly in the flip flop.

The first value written into the D flip flop is ‘‘zero’’, the ‘‘data’’ line’s value for the write is changed before the ‘‘clock’’ line goes negative. When the ‘‘clock’’ line goes low, it forces out a ‘‘1’’ to be passed to the ‘‘right’’ flip flop, keeping it in its current state. The operation of the edge triggered flip flop should become very obvious if you were to build it (it would require two 74C00s).

I find the D flip flop to be the flip flop that I build into my circuits most often. It is simple to work with and can interface to microcontrollers and microprocessors very easily. It is, however, quite awkward to wire, especially when you want to work with the ‘‘full circuit’’, which is shown in Fig. 7-17. This circuit not only has data stored on the rising edge of the clock line but also two other lines ‘‘_Clr’’ and ‘‘_Pre’’ will force the flip flop’s output to a ‘‘0’’ (low voltage) or a ‘‘1’’ (high voltage), respectively, when they are pulled low. This allows for a number of different options for using the D flip flop in your circuit that can allow you to pull off some amazing feats of digital logic.

If you want to experiment with this circuit using two input NANDs (74C00s), I must warn you that it will be quite difficult and complex for you to wire. If you were to use three gates to produce one three input NAND gate, 18 NAND gates would be required to implement the full D flip flop function, which would require four and a half 7400 chips. To demonstrate the operation of the circuit, you could build it out of two 7410 (three, three input NAND gates) or be lazy like I am and just use one 74LS74 (Fig. 7-18) to experiment with the different functions of the full D flip flop.

The 7474 chip consists of two D flip flops with both the ‘‘Q’’ and ‘‘_Q’’ outputs passed to the chip pins. All four inputs shown in Fig. 7-18 (Data and Clock as well as two pins that provide you with the ability to set or reset the state of the flip flop without the use of the data or clock pins) are provided for each of the two flip flops built into the chip. The 7474 is a very versatile chip and can be used for a wide range of applications.

Latches Versus Registers

Two terms that are often used interchangeably are ‘‘register’’ and ‘‘latch’’. In the previous section, I introduced you to the ‘‘register’’, which is another term for an edge triggered flip flop. When you look at parts lists and datasheets, you will see parts that are identified as "registers" and others as "latches" and these parts will have the same pinouts with no obvious differentiation in operation between the devices. Furthermore, I have found many chip manufacturers that have labeled their parts as "latches" when in fact they were "registers" and vice versa.

Quite simply put, "registers" are flip flops that store data when the rising (low to high or 0 to 1) or falling (high to low or 1 to 0) edge (whichever is used by the device) is received on the "clock" (or, my abbreviation, "Clk") pin. Registers are aptly named because they are normally used as simple data storage devices for microprocessor memory. Latches are often used in microprocessor applications to save an address on a multi-purpose bus.

The best analogy for the "latch" that I can think of is a latch on a barn door: when the latch is not engaged, animals and whatever can wander in. Once the latch is closed, what is in the barn stays in. The "latch" flip flop works similarly to this; with one state of the clock line, the input data is passed to the output directly and can be changed at any time (i.e. there isn't any storage) but once the clock line changes state, the last value of the data is stored in the latch until the clock changes value.

In the previous section, I introduced you to the edge triggered D flip flop "registers". The D flip flop "latch" is actually quite a bit simpler (Fig. 7-19), but what is interesting about it is that it doesn't work anything like its edge triggered cousin. In Fig. 7-20, I have drawn a data input along with a clock and the "Q" (output pin) values for an edge-triggered D flip flop register and a D flip flop latch.

You will probably be surprised to see that waveforms for the two memory devices are completely different. The edge triggered D flip flop register stores data in a very consistent and logical way – every time the clock pin

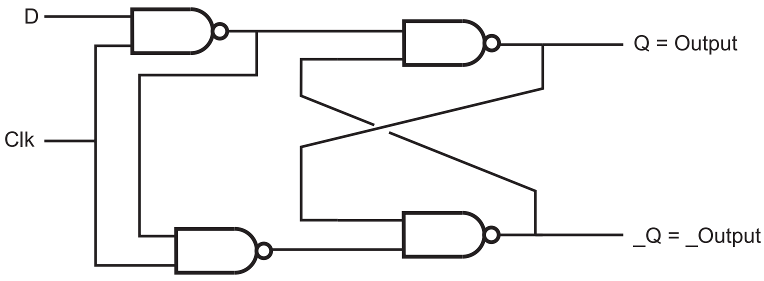

Fig. 7-19. D flip flop latch.

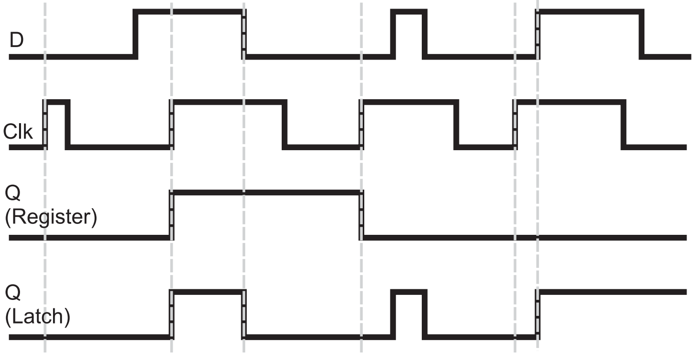

Fig. 7-20. D flip flop latch operating wave form.

rises, the value of ‘‘D’’ is stored in the flip flop and nothing changes until the next rising edge of the clock pin.

The latch, on the other hand, seems to operate more like an AND gate than a memory storage device. The storage function tends to be obfuscated in the example of Fig. 7-20 because in many cases, I show the D pin changing state before the clock line returns low. This is an important point because many people consider the two devices to be interchangeable and this is simply not the case. Latches and registers have different applications and it is critical for you to understand what they are. You cannot put a latch chip in place of a register simply because they are pin compatible; you must make sure that the incoming data does not change state until the clock goes low.

Interestingly enough, latches do not need as much time to save data as a register; there are 9 fewer gate levels for a signal to pass through and even though I show the data save operations being instantaneous in Fig. 7-20, they are not. The latch can take as little as one-third of the time to save data as a register and only requires two gate delays before passing the data along (after which the data can be stored). This makes the latch an important chip for working with microprocessors with a ‘‘multiplexed’’ address bus.

Reset

If you cycle the power to any flip flop, you will have noticed that the initial ‘‘state’’ (or value) can be either ‘‘0’’ (LED off) or ‘‘1’’ (LED on), with no way of predicting which value it will be. This is normal because when power is applied to the flip flop it will start executing in the metastable state, and for any kind of imbalance in the circuit (e.g. residual charge or induced voltage) on the inputs of either NAND/NOR gate, the flip flop will respond and this will be its initial state. Often, this random initial state is not desired – instead, the circuitry should power up into a specific known state for it to work properly. This is why throughout this chapter I have taken pains to note that the initial state of a flip flop is not known. You may find that an application with one flip flop usually powers up the same way; if you were to do a statistical analysis of the power up values, you might even find that a single power up state approaches 100%, but you cannot guarantee this for all occurrences of the chip, or even that all other similar chips in the same application circuit will power up the same way.

Specifying the state when the circuit is powered up is known as "initialization" (just as it is for programming) and is required for more than just sequential logic circuits. Initialization normally takes place when the application is "reset", or waiting to start executing. To avoid confusion later, I should point out there are two types of "reset" described in this book when I talk about digital circuits. Earlier, when I was talking about simple combinatorial circuits, I also called a "low" or "0" voltage level "reset" (and "high" or "1" as "set"). Now, when the term "reset" is used, I am describing the state when the circuit is first powered up or stopped to restart it from the beginning. When you read the term "reset" later in the book (as well as in other books), remember that if a single bit or pin is being described, the term "reset" means that it is "0" or at a low level. If a sequential circuit (like a microcontroller) is "held reset" or "powering up from reset", I mean that it is being allowed to execute from a known state.

The "_CLR" pin on the full D flip flop (like the 7474) is known as a "negative active control" and is active when the input is at a "0" logic level. To make this pin active during power up, yet allow the chip to function normally, a resistor/capacitor network on the TTL input pin delays the rise of the pin (as shown in Fig. 7-21) so that the pin is active low while power is good. When the signal on "_CLR" goes high, and the clear function is no longer active, the chip can operate normally, with it being in an initial known state.

The time for the RC (resistor/capacitor) network to reach the threshold voltage can be approximated using the equation:

$$\texttt{Delay time} = 2.2 \times \texttt{R} \times \texttt{C}$$

When you work with microprocessors and microcontrollers, you will want to implement a more sophisticated reset circuit. Many microprocessor manufacturers recommend an analog comparator based reset circuit like the one shown in Fig. 7-22. This circuit controls an open collector (or open drain)

transistor output pin that will pull down a negative active reset pin when power dips below some threshold value. This circuit is often available as a "processor reset control" chip and is put into the same black plastic package as a small transistor (known as a TO-92).

Processor reset control chips are available for a very wide variety of different "cut off" voltages, ranging from 2.2 volts and upwards. Figure 7-23 shows the operation of the internal parts of the processor reset control chip when the input voltage drops below the set value; the comparator stops outputting a "1" and a delay line is activated. This delay line is used to filter out any subsequent "glitches" in the power line and makes sure that the power line is stable before allowing the processor to return from reset and continue executing. When the comparator outputs a low value or the delay line is continuing to output a low value, the output of the NAND gate they are connected to is high and it turns on the open collector output transistor, pulling the circuit to ground.

The Panasonic MN1381 line of chips is a very popular processor reset control and can be used to control a sequential circuits reset using

a circuit similar to the one shown in Fig. 7-24. This circuit will take advantage of the RC network delaying the rise of the control signal, provide you with the ability to reset or stop the operation of the microprocessor and halt the operation of the robot if the battery falls below a safe minimum.

If you power on and off a circuit quickly, you may find that it does not power up properly. This is due to the capacitor in the reset circuit not discharging fully – it may take as much as 10 seconds for it to discharge completely. This was actually an issue with the original IBM PC; if you had a situation where the PC ‘‘hung’’, you would have to power down and wait at least 15 seconds to make sure that the reset circuit would allow the computer to power up properly.

Quiz

1. Feedback in digital electronics:
   (a) Is built into every gate
   (b) Must always be avoided
   (c) Can be used to store bit data
   (d) Is only used in radio interface circuitry

2. Ring oscillators can be used:
   (a) In digital watches
   (b) To measure the gate delay of a logic technology
   (c) To test the operation of a combinatorial circuit
   (d) Only when current limiting resistors are in place to protect gate outputs

3. What do the letters "R" and "S" stand for in the RS flip flop?
   (a) "Recessive" and "Static"
   (b) "Reset" and "Set"
   (c) "Rothchild" and "Stanislav"
   (d) "Receive" and "Send"

4. What is the "metastable state" of a flip flop?
   (a) When it has started to oscillate
   (b) The time between when the inputs change the output is correct
   (c) The state in which the outputs of a flip flop are half way between "0" and "1" and can be easily "pushed" into a specific state
   (d) The state in which "Q_0" is unknown

5. "Toggling" a bit means:
   (a) Setting (making the output a 1) of a bit
   (b) Leaving the bit in its current state
   (c) Inverting the bit's state
   (d) Resetting (making the output a 0) of a bit

6. A "Register" can be used in:
   (a) Nowhere, it is a thought experiment used to show feedback in a digital application
   (b) Just computer processors
   (c) Just sequential digital electronics application
   (d) Just about any digital electronics application

7. The "_Pre" pin of a D flip flop will:
   (a) Set the bit
   (b) Reset the bit
   (c) Nothing
   (d) Toggle the state of the bit

8. Which formula specifies the RC network response to a sudden voltage input?
   (a) $V = 2.2 \times R \times C$
   (b) $V = Vcc - Vcc \times e^{-t/RC}$
   (c) $V = Vcc \times e^{-t/RC}$
   (d) $V = i \times R$

9. Why are latches like barn doors?
   (a) They provide a secure environment for what's inside them
   (b) They are both relatively heavy
   (c) They allow free passage until the latch is engaged
   (d) They are the fastest method for passing things in and out

10. Which application is a latch best suited for?
   (a) Main memory in a computer system
   (b) Bicycle lock combinations
   (c) Stopping and saving data mid-stream
   (d) Temporary storage of data in a microprocessor

Test for Part One

Do not refer to the text when taking this test. You may draw diagrams or use a calculator if necessary. A good score is at least 38 correct answers. Answers are in the back of the book. It's best to have a friend check your score the first time so you won't memorize the answers if you want to take the test again.

1. The assertion "John is going to go out with the boys tonight or date Mary" is an example of:
    (a) Negative logic
    (b) The AND operation
    (c) The inclusive OR operation
    (d) The exclusive OR operation

2. Which symbol does not represent AND, OR or NOT?
    (a) "*"
    (b) %
    (c) "+"
    (d) "!"

Copyright © 2005 by The McGraw-Hill Companies, Inc. Click here for terms of use.

3. How would you create a three input NOR gate from two input NOR gates?
   (a) Invert each input by passing them to a two input NOR gate and then combining it like the three input AND gate
   (b) Pass two inputs to a NOR gate and pass this input to a second NOR gate along with the remaining input and invert the final result
   (c) Pass two inputs to a NOR gate, use a second NOR gate to invert this NOR gate's output and pass this result, along with the third input to a third NOR gate
   (d) Pass two inputs to a NOR gate and pass this input to a second NOR gate along with the remaining input
4. "Product of sums" combinatorial logic circuits are not as common as "sum of products" because:
   (a) They rely on "negative logic", which makes their operation more difficult to understand by simply looking at the circuit
   (b) They are not as fast as product of sums combinatorial circuits
   (c) Automated design tools are typically not programmed to work with product of sums circuits
   (d) Product of sums combinatorial logic circuits cannot produce the same functions as sum of product combinatorial logic circuits
5. Which one of the following statements is false?
   (a) Combinatorial logic circuits are drawn with inputs entering the gates from the left and exiting from the right
   (b) Outputs from some of the gates in the combinatorial are passed back so that they are part of their own inputs
   (c) Combinatorial logic circuits can be designed to have true or false outputs for given inputs
   (d) The function of the individual gates in a combinatorial logic circuit does not change, even if the gates are used to provide a function which is radically different
6. Idealized waveform diagrams do not show:
   (a) Potential "glitches" caused by gates changing state
   (b) Delays in gates, responding to changes in inputs
   (c) What happens with wiring problems such as when multiple outputs are connected to the same input
   (d) All of the above

7. If an application has a critical speed requirement, you should design your circuit:
   (a) To be as simple as possible, as this will minimize the delay a signal has passing through the circuit
   (b) With as few gate delays as possible, while keeping an eye on the number of gates required as well as whether or not it can be efficiently implemented in the technology that you are using
   (c) Using the fastest technology available
   (d) Using computerized design systems

8. The NOR equivalent to an AND gate is:
   (a) Built from two NOR gates and requires two gate delays for a signal to pass through
   (b) Built from three NOR gates and requires three gate delays for a signal to pass through
   (c) Built from three NOR gates and requires two gate delays for a signal to pass through
   (d) Built from one NOR gate as well as a NOT gate and requires two gate delays for a signal to pass through

9. When circling “1” outputs in a Karnaugh map:
   (a) A maximum of two bits can only be circled at one time
   (b) No bits can be circled more than once
   (c) Each circle should be around a power of two number of bits
   (d) Single bits on one side of a the map cannot be circled with bits on the other side

10. The four bit Karnaugh map

	AB			
	00	01	11	10
CD – 00	0	0	1	0
01	1	1	1	1
11	0	1	1	0
10	1	0	1	1

has the optimized sum of product equation:
   (a) $\text{Output} = (!B \cdot !D) + (!A \cdot !B) + (C \cdot !D) + (B \cdot !C \cdot D)$
   (b) $\text{Output} = (A \cdot B) + (!C \cdot D) + (B \cdot D) + (!B \cdot C \cdot !D)$

(c) Output = $(!C \cdot !D) + (A \cdot B) + (B \cdot D) + (!B \cdot C \cdot !D)$
(d) Output = $(A \cdot B) + (!C \cdot D) + (B \cdot !D) + (!B \cdot C \cdot !D)$

11. Benjamin Franklin postulated:
(a) Electricity flows from positive to negative
(b) Lightning is dangerous
(c) Keys had to be charged before they would open doors
(d) Thomas Edison unfairly copied his work

12. The term "net" is used for:
(a) Wires in a circuit and lines on a circuit diagram
(b) Indicating the active signal lines of an ethernet cable
(c) A search tool through which information is passed through and relevant "hits" sticks to
(d) Nylon webbing used to protect a circuit against falling metal components.

13. Knowing Ohm's law and the resistance of a load and the voltage of a battery powering it, you can determine:
(a) The current passing through it
(b) The amount of water coming through an analogous pipe/tap/hose
(c) Its equivalent parallel resistance
(d) The Thevenin equivalent circuit

14. Using the SI numbering methodology and symbols, 10,000,000 volts would be written out as:
(a) 10 million V
(b) 10 MV
(c) 10 μV
(d) 10,000,000 V

15. The voltage drop across a resistor in a series circuit:
(a) Cannot be calculated
(b) Is proportional to the power dissipated in the circuit
(c) Is always zero
(d) Is proportional to the resistor's value relative to the total resistance in the circuit multiplied by the applied voltage

16. If a 10 ohm and 20 ohm resistor are in series, the equivalent resistance:
(a) Cannot be calculated without knowing the voltage applied
(b) 30 ohms
(c) 7.5 ohms
(d) 6.7 ohms

17. A 0.01 μF capacitor is most often used in:
    (a) Radio applications; it has no use in digital electronics
    (b) Decoupling digital electronic chips
    (c) Filtering power supply "noise"
    (d) Ballast in fluorescent lighting

18. The value at a given time for the capacitor voltage in a resistor–capacitor low-pass filter circuit responding to a rising step input is:
    (a) Infinite
    (b) Defined by the formula $V(t) = V - V \times e^{-t/\tau}$
    (c) Defined by the formula $V(t) = V \times e^{-t/\tau}$
    (d) Zero; the capacitor has no voltage drop across it

19. The NOR gate was chosen as the basic CMOS logic gate because:
    (a) It can be built most efficiently using MOSFET transistors
    (b) It provides the fastest logic functions in CMOS logic
    (c) It helps the circuit designer differentiate the functions provided by TTL and CMOS logic circuitry
    (d) The NOR gate minimizes the power lost in the chip

20. Which statement is not a reason cited for using resistor pull ups and resistor/NOT gates for pull downs?
    (a) The resistor can be connected to negative voltage without damaging the circuit
    (b) Test equipment can easily change the state of logic pin inputs
    (c) TTL and CMOS logic operate optimally with these circuits
    (d) The resistor pull ups and resistor/NOT gate pull downs will work for both TTL and CMOS logic

21. If a silicon diode was passing 2 A of current, it would be dissipating:
    (a) 14 watts of power
    (b) 0.2 watts of power
    (c) 0 watts of power
    (d) 1.4 watts of power

22. In a 5 volt powered circuit, you have two LEDs in series and want to pass approximately 5 mA through them. What is the best current limiting resistor value should you use?
    (a) 47 ohms
    (b) 100 k ohms
    (c) 5 ohms
    (d) 1 k ohms

23. A bipolar transistor is best suited for:
    (a) Radios and high-fidelity sound systems
    (b) Small, high-density chips
    (c) Memory circuits
    (d) Low-power, high-density chips

24. The basic CMOS logic gate is:
    (a) The NOT gate
    (b) The AND gate
    (c) The NOR gate
    (d) The NAND gate

25. TTL is:
    (a) Sound controlled
    (b) Resistor controlled
    (c) Current controlled
    (d) Voltage controlled

26. When a TTL input is low:
    (a) Current is being drawn from it
    (b) A low voltage is being applied to it
    (c) A "0" is being passed to it
    (d) Electrons are being drawn from the emitter of the input gate's NPN transistor

27. TTL/CMOS logic outputs:
    (a) Can be used to drive neon lamps
    (b) Can source/sink roughly 20 mA
    (c) Cannot be used with different technology inputs
    (d) Are limited to driving inputs less than 20 m away

28. "Fanout" is the term applied to:
    (a) The number of outputs that can be driven by one input
    (b) The number of fans required to cool a set number of chips
    (c) The speed a signal travels through multiple paths of a logic chain
    (d) The number of inputs that can be driven by one output

29. CMOS logic has the following characteristics:
    (a) They are low speed, low power
    (b) Require just about no power, regardless of the speed they operate at

(c) The current required is a function of the speed of operation
(d) Require less power than TTL because MOSFETs cannot be packed as tightly as bipolar transistors

30. LEDs are used in beginner digital electronic circuits:
(a) To indicate analog voltage levels
(b) To indicate a part is overheating
(c) To indicate input and output binary values
(d) To communicate with other circuits

31. The difference between 74Cxx and 74xx chips is:
(a) The 74Cxx is built from CMOS logic while the 74xx is TTL
(b) Signals in the 74Cxx propagate at the speed of light (as indicated by the ‘‘C’’ in the part number)
(c) The 74xx can work from 5 to 9 volts while the 74Cxx can only work with 5 volts
(d) The 74Cxx is built with a ‘‘compacted’’ chip

32. Gray codes were invented:
(a) To make your life miserable
(b) For simplifying Boolean logic statements
(c) For simplifying the task of determining the position of a device
(d) As a method of counting that was faster than binary

33. Adding 6 to 5 and getting the result 11 is the same as:
(a) Adding 7 to 4 and getting the result 11
(b) Adding 3 to 4 and getting the result 7 because in both cases, a prime number is produced
(c) Adding 5 to 6 using the commutative law and getting the result 11
(d) Adding 6 to 5, writing down ‘‘1’’ and then ‘‘10 × 1’’ because a carry digit is produced

34. The term ‘‘ripple’’ as applied to addition and subtraction is:
(a) The carry and borrow bits
(b) The result of the two single digit operation passed to the next significant digit
(c) The affect the operation has on its surrounding digits
(d) The oscillations caused by the need to carry and borrow data

35. Using the negated addition for subtraction, the borrow (negated carry) bit for the operation 5 – 6 is:
(a) Not required
(b) 1

(c) 0
(d) Indeterminate

36. A small circle on a gate's input indicates:
    (a) That the signal can only be used for output.
    (b) That the signal is inverted before being passed to the gate
    (c) Only open collector drivers can be used with this input
    (d) The I/O can be used for monitoring the passage of the signal output in the gate

37. Magnitude comparators are based on:
    (a) Three initial input state values
    (b) Two four bit inputs
    (c) Two subtracters
    (d) One subtracter and one adder

38. Cascading chips is usually required because:
    (a) Faster speed is required than a single chip can provide
    (b) More bits must be processed than a single chip can handle
    (c) The only chips that can provide all the necessary function require too much power
    (d) It minimizes the cost of a circuit

39. Dividing a binary number by 8 can be accomplished by:
    (a) Clearing the least significant three bits
    (b) Shifting left three bits
    (c) Shifting right three bits
    (d) Setting the least significant three bits

40. Mickey Mouse logic solutions should be placed in the circuit:
    (a) In the middle of a logic string
    (b) On the inputs of a logic string
    (c) On the outputs of a logic string
    (d) Where high-current I/O is required

41. The resistor used in the Mickey Mouse logic AND gate shown in Fig. Test 1-1 should be:
    (a) 10 k for TTL applications
    (b) 10 k for CMOS applications
    (c) The complementary one specified by the diode's manufacturer
    (d) Power rated for the load current of the application

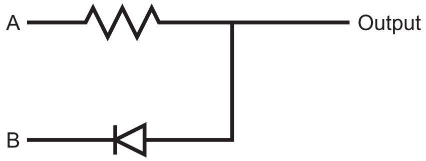

Fig. Test 1-1.

42. Each item below is a disadvantage of a dotted AND bus except:
    (a) High power consumption when the output is low
    (b) The dotted AND bus has a slower response than tri-state buffers
    (c) The dotted AND bus is cheaper than one manufactured with tri-state drivers
    (d) It is very difficult to find open collector output chips

43. When providing multiple functions to a net, what logic technology/ technologies should be used?
    (a) Just CMOS
    (b) Just TTL
    (c) CMOS receivers and TTL drivers
    (d) TTL receivers and CMOS drivers

44. Sequential circuits contain:
    (a) Memory devices
    (b) Power supplies
    (c) Input and output devices
    (d) CMOS logic

45. Backdriving gates can:
    (a) Simplify your application design
    (b) Speed up gate operation
    (c) Change the input of a downstream device
    (d) Burn out the gate's output transistors

46. What is the difference between "Q_0" and "_Q_0"?
    (a) There is no difference
    (b) "Q_0" is correct earlier than "_Q_0"
    (c) "Q_0" is current state of the flip flop and "_Q_0" is the previous
    (d) "_Q_0" is the inverted value of "Q_0"

47. The "_Clr" pin of a D flip flop will:
    (a) Set the bit
    (b) Reset the bit
    (c) Nothing

(d) Toggle the state of the bit

48. Which full D flip flop input pin is typically connected to the RC delay circuitry?
(a) D
(b) Clk
(c) _Clr
(d) _Pre

49. Which application is a register best suited for?
(a) Main memory in a computer system
(b) Permanently storing access passwords
(c) LED output states
(d) Temporary storage of data in a microprocessor

50. "Volatile memory" means:
(a) The contents of the memory device will not be lost when power is taken away
(b) The contents of the memory device will be lost when power is taken away
(c) The memory device is made up of a liquid which will evaporate if the chip package is broken
(d) Data is stored as patterns of a condensed gas

CHAPTER 8

Oscillators

In the introduction to the previous chapter of this book, I presented you with a simple block diagram of a "complete" digital electronic device: the digital clock. This device has all three of the necessary components for a functional, "stand alone" device: combinatorial logic for converting binary data as required; a memory function which "remembers" the last state it was in; and a clock or "oscillator" which synchronizes the functions together. The science of oscillator design is extremely rich and, as I will show in this chapter, there are a lot of options that you can choose from to make sure your application operates most efficiently.

It could also be argued that there is a fourth component to producing a complete, stand alone digital device – the power supply. Power supply design is a facet of electronics which is just as rich and sophisticated as digital electronics or any other major study in electronics. While I introduce you to some of the basic types of power supplies that are available to you later in the book, this does little more than just scratch the surface of this complex topic.

The application's "clock" is a set of repeating pulses (ideally with the same "on" and "off" time) which is input into the sequential circuits of an application to carry out the operations within them. Figure 8-1 shows an ideal digital electronic clock waveform with the important features marked

Fig. 8-1. Features of a clocking signal.

on it. The frequency output of a clock is measured in "hertz" (cycles per second), which is the reciprocal of the time the pulse is on added to the time the pulse is off:

$$\texttt{Frequency} = 1/(\texttt{Time "On"} + \texttt{Time "Off"})$$

A rather obvious example of this would be a 1 pulse per second signal that is used to drive the sequential circuits of a timekeeping clock. The term "clock" is probably confusing, as the digital "clock" that I have defined is only very rarely used to tell the time. The clock signal that I am discussing in this section is used to drive the digital counters of the timepiece.

The "clock" in a digital circuit is driven from an "oscillator" that uses some form of feedback to toggle the clock line in a consistent manner. In this book, you will find that I use the terms "clock" and "oscillator" interchangeably, with the clock or oscillator signal being responsible for the operation of the digital circuit.

In Fig. 8-1, I noted the important features of a clock signal to be its constant period as well as its 50% duty cycle. If the clock is not constant and you were to look at the operation of the clock and the digital circuit on an oscilloscope, you would see the signals blur as they "jittered" back and forth. The shortened or lengthened features of a clock waveform are called "jitter" and are shown in Fig. 8-2. Jitter is a problem from a couple of perspectives. First, it makes it very difficult to observe the operation of a circuit using an oscilloscope, making it hard to debug an application. Secondly, the combinatorial logic parts of sequential circuits are often designed to have completed their bit data processing by the time the clock has completed; a shortened clock cycle, like the one shown in Fig. 8-2 could result in incorrect data being stored in a circuit.

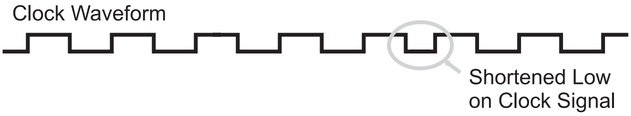

Fig. 8-2. Clock waveform with ‘‘jitter.’’

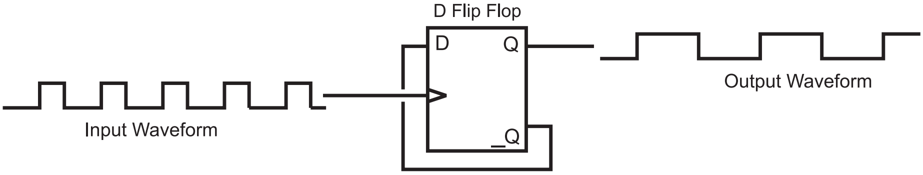

Fig. 8-3. Clock divide by 2 conditioning circuit.

Incorrect logic operation caused by jitter is extremely difficult to capture on an oscilloscope or a logic analyzer. If you have errors and have a clock with jitter, you would be well advised to assume that the jitter is the problem and look towards another clocking scheme. Jitter is often caused by voltage transients caused by different parts of a digital electronic circuit changing state; often it can be reduced or eliminated by providing better noise filtering between the oscillator circuit and the digital logic devices.

In Fig. 8-1, I indicated that the ideal ‘‘duty cycle’’ of a clock signal is 50%. I will discuss duty cycles in more detail later in the book when I present PWMs, but for now, you should understand that the duty cycle is the percentage of the period in which the waveform is high. Ideally, the clock should have a 50% duty cycle (be high for half the period) to minimize harmonics, simplify using an oscilloscope or logic analyzer to observe the operation of the circuit and, because some digital electronic devices (most notably microprocessors) poll both the high and low of the clock signal, to help speed up its operation.

In some oscillator circuit designs, the output does not come close to having a 50% duty cycle and in these cases, some kind of signal ‘‘conditioning’’ is required. The most basic way of ensuring the clock signal has a 50% duty cycle is to use an edge triggered D flip flop as I show in Fig. 8-3. The D flip flop (called a ‘‘toggle flip flop’’ when wired this way) will only change its output when a triggering edge on the input clock has been received. The only drawback to this circuit is that it halves the frequency of the clock, so, in some cases, to use this circuit you will have to double the clock output frequency.

There are many different designs of oscillators that you can choose from. In this chapter I will introduce you to many of the most common ones along with their characteristics and the formulas required to work with them.

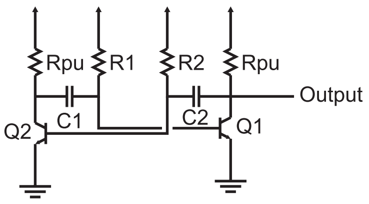
Transistor Astable Oscillators

When I was growing up, all educational and hobbyist circuits were built up from individual transistors – it wasn't until the mid to late 1970s that ''building block'' chips such as the 555, LM339, LM386, and LM741 started to be commonly used in circuits. These chips are all very configurable, but none offer the range of operation and low cost of discrete transistors. The term ''astable'' indicates that the oscillator circuit is never stable; its output will continue to switch from high to low and back again. The science of oscillators can be thought of as ''taming'' the oscillator in terms of frequency, duty cycle and jitter.

A very common and relatively simple oscillator circuit that I am going to examine is the basic ''relaxation oscillator'' circuit shown in Fig. 8-4. Included in Fig. 8-4 are the defining formulas for the time that the output is high and low as well as an important formula indicating that the value of R1 and R2 (the time defining resistors) must be the transistor h_{FE} multiplied by the value of the pull up resistors (Rpu). If R1 or R2 is less than this product, then you will find that the oscillator will not start reliably and not run at a constant frequency.

The operation of the relaxation oscillator is illustrated in Figs. 8.5 through 8.7. In Fig. 8-5, I show an initial condition where one transistor is on and the other is off. In this case, the capacitor by the on transistor is charging because its cathode is being pulled to ground by the ''on'' transistor. The other capacitor is unable to be charged because the transistor connected to its cathode is off, holding the voltage at the cathode at the same voltage as the anode.

In Fig. 8-6, the capacitor that was charging in Fig. 8-5 has finished and any current passing through the resistor is passed to the other transistor, turning it on. By turning on this transistor, the capacitor's cathode connected to its collector is now tied to ground and it is able to be charged. With this capacitor now charging, the current that was once available to the



$\text{Output}_{High} = \text{Q1}_{Off} = 0.69 \times \text{R1} \times \text{C1}$

$\text{Output}_{Low} = \text{Q1}_{On} = 0.69 \times \text{R2} \times \text{C2}$

$\text{R1} = \text{R2} = h_{FE} \times \text{Rpu}$

transistor's base to turn it on is no longer available and the transistor turns off. This raises the collector of this transistor to the applied voltage and, along with this, the cathode of the capacitor connected to it. This places the charge in the capacitor tied to the collector of the transistor just turned off at a voltage higher than the applied voltage, so its charge is now passed to the transistor that was just turned on. In the final case (Fig. 8-7), the operation of

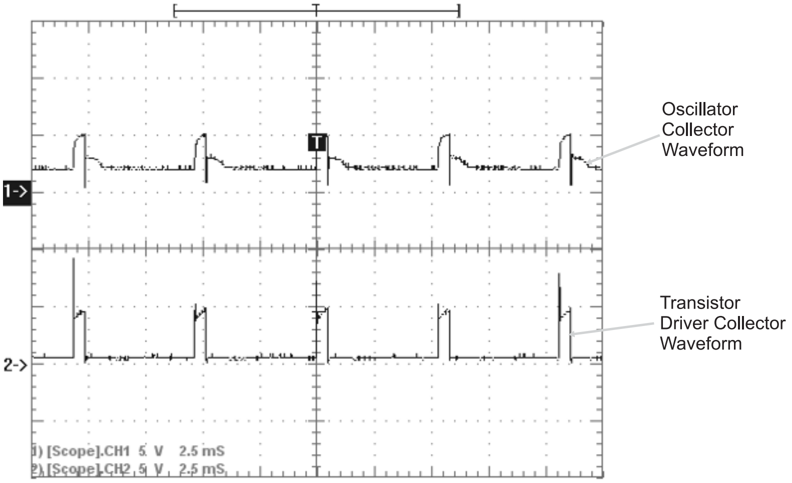

Fig. 8-8. Relaxation oscillator waveforms.

the oscillator circuit is the mirror image of the initial conditions shown in Fig. 8-5. When the charging capacitor is finished, its current is passed to the transistor that is currently turned off and the process repeats itself.

The output of this oscillator is probably nothing that you would expect – Fig. 8-8 is an oscilloscope display of a sample NPN transistor relaxation oscillator output as well as the collector voltage. The duty cycle of the waveform is nowhere close to 50% (which means it will have to be conditioned by some kind of circuit, like the one in Fig. 8-3. However, this circuit is quite good in terms of accuracy, with very little jitter.

The drawbacks to using a transistor oscillator like the one presented in this section include the unusual waveform output and the use of discrete analog components for timing the oscillator. The unusual waveform output makes the need for some kind of signal condition mandatory when working with digital electronics and the use of analog components makes the frequency output quite imprecise. The characteristics of the transistor-based oscillator make it best suited for low-cost applications where clocking accurate to 20% is acceptable.

Ring Oscillators

In the previous chapter, I introduced the concept of “ring oscillators” as being a digital electronic device in which an inverted output signal is fed back to the input of a combinatorial circuit and showed that it could be created inadvertently (Fig. 8-9) or purposely using a single logic inverter (Fig. 8-10). One of the useful characteristics of the ring oscillator is that it will always produce a 50% duty cycle and its output is literally the maximum speed of the technology.

I should say that the ring oscillator's maximum output is the maximum speed of the technology. In Fig. 8-10, I have drawn two ring oscillators, the first outputting the signal from a single inverter – the period of the output of this circuit will be 1 gate delay. In the lower diagram of Fig. 8-10, I show that you are not limited to just running at the technology's maximum speed; by adding an even number of additional inverters to the ring oscillator, the output signal's period can be lengthened.

The ring oscillator's actual frequency output can be ''tuned'' by varying the number of inverters in the ring oscillator along with the technology used in the inverters. Knowing this, along with a couple of operating rules, provides you with an inexpensive, high-speed oscillator that is quite reliable and robust.

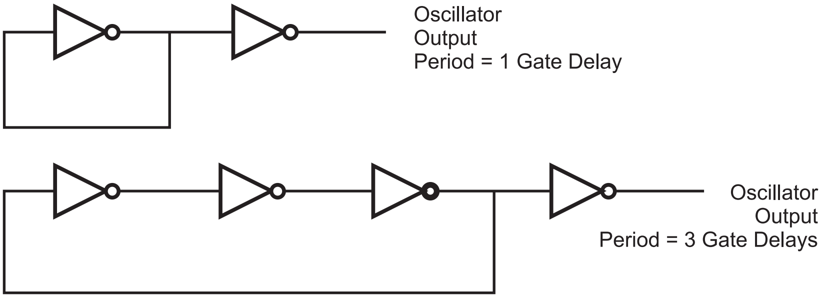
Fig. 8-9. Inadvertent ring oscillator.



Oscillator
Output
Period = 1 Gate Delay
Oscillator
Output
Period = 3 Gate Delays

Fig. 8-10. Ring oscillators using gate delays for frequency determination.

The first of the operating rules should not be surprising because I have alluded to it in the text above: the number of inverters in a ring oscillator should always be odd. If an even number of inverters is used in a ring oscillator, there will be no signal which cannot be resolved (which is the cause of the "astable" operation of an oscillator) and the circuit will not oscillate. The second operating rule is that no other functions should be used by the leftover gates in the chip and the chip's power pins should have both small (0.1 μF or less) and large (1.0 μF or greater) decoupling and filter capacitors on its power supply. The oscillating gates within the chip are experiencing significant transients which could affect the operation of other devices in the application.

While I have only used ring oscillators a couple of times over the years, they are fascinating circuits to build and watch executing. The ring oscillator is what I consider to be a "hip pocket" circuit: something to be pulled out only when nothing else seems to work or have the characteristics that you require.

Relaxation Oscillators

The most basic type of logic chip based oscillator is the "relaxation" oscillator which feeds back the output of an inverter through a "resistor/capacitor" ("RC") network to delay the switching of the oscillator. The basic circuit and its defining output equation is given in Fig. 8-11.

In this circuit, the R1 and C network are driven by the first inverter and the characteristic "RC" response is fed back to the first inverter's input. When the voltage on the capacitor reaches the threshold voltage of the left inverter input, the inverter changes state and drives a new output voltage. This voltage is again passed through the R1, C network and delayed until the threshold voltage is reached again.

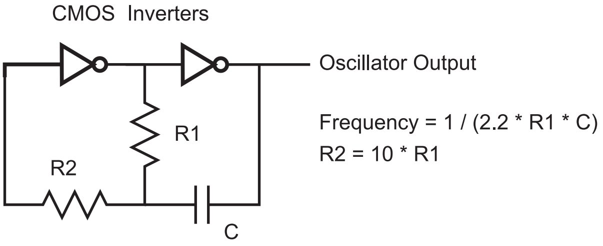


Fig. 8-11. CMOS logic technology relaxation oscillator.

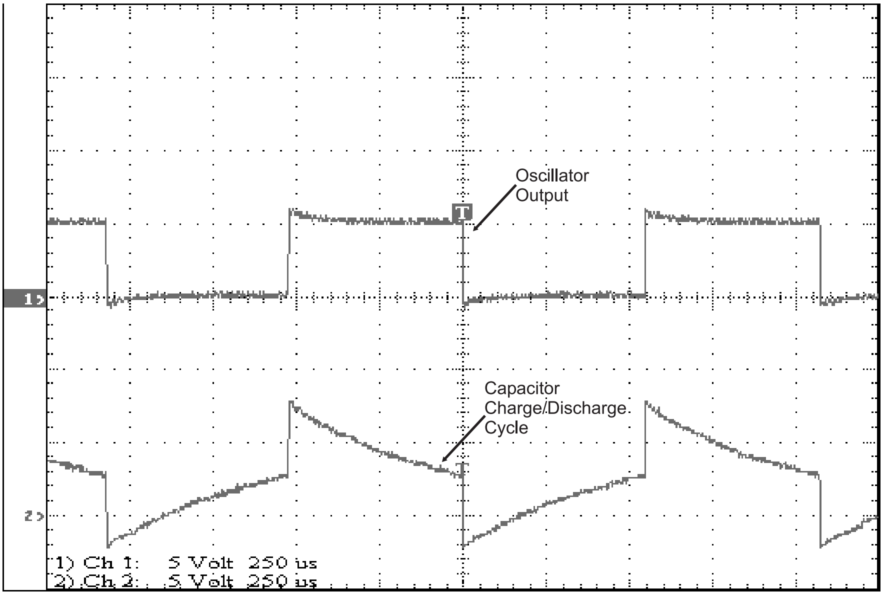

Fig. 8-12. CMOS relaxation oscillator waveform.

In Fig. 8-12, I have shown the voltage waveforms at the R1, R2 and C junction of this circuit as well as the output voltage signal. Note that the R1, R2 and C junction voltage exceeds the Vcc/Gnd (+5 volts and 0.0 volt) limits. This is due to the capacitor being connected to the output driver.

Having the capacitor wired to the output driver "moves" the charge (and the capacitor voltage) by 5 volts each time the state changes. Observing the circuit's operation from the capacitor, the output value changes the charge within the capacitor until it is back at the threshold voltage for the CMOS inverter, which is 2.5 volts (one-half applied power). You can see in Fig. 8-12 that the transitions take place every time the voltage across the capacitor is at 2.5 volts relative to Gnd.

CMOS inverters are used in this circuit because they are voltage controlled rather than current controlled and this makes the oscillator's operation easier to understand. A TTL inverter cannot be used in this circuit because of the current drain operation required by the input when a "0" is input will affect the operation of the oscillator. A Schmidt trigger input device (i.e. the 74HC14) could be used, but it is not necessary because the reference voltage of the capacitor is changing with every transition.

You may want to test out this circuit with a 74C04 or 74HC04 with a 4.7 k resistor, a 47 k resistor and 0.1 μF capacitor to create an oscillator that produces a clock signal of approximately 1 kHz. I say that the output is "approximately" 1 kHz because of the tolerances of the parts used in the circuit. For the circuit used to produce the signal shown in Fig. 8-12, I used a 0.1 µF tantalum capacitor for the "C" in the relaxation oscillator circuit. This is probably not a "correct" use of a tantalum capacitor, as they can have tolerances approaching 30% of their rated value – I only used it because I have a lot of them around. Along with the tolerance of the capacitor, there are also the tolerances of the resistors in the circuit to consider as well. These tolerances result in the opportunity for the actual clock signal to be "out" by 40% or more.

Your immediate response may be to add a potentiometer (variable resistor) into the circuit and "tune" it to the exact frequency that you want. Personally, I would discourage this practice as it involves a lot of work (especially if production parts are involved), which will drive up the cost of the product. If you are using a simple RC relaxation oscillator in your application, then additional costs are something that you would want to avoid. The relaxation oscillator is adequate for many applications where a low-cost oscillator of an approximate value is required. Like the NPN transistor astable oscillator, I recommend that the circuit should not be used in any applications where any kind of precision is required.

Another aspect of this circuit that you must be aware of is the potential for large current transients within the chip that are produced to change and discharge the capacitor. These transients are similar to the transients discussed in the ring oscillator. For most circuits, this is not a problem, but if you have other sensitive circuits built into an application, you will want to keep the relaxation oscillator (as well as any other oscillators in the circuit) as electrically removed as possible from the other chips by using both large and small decoupling and filtering capacitors. Also like in the ring oscillator, as a rule of thumb, no other gates should be used in a chip if it is being used as an oscillator.

Crystals and Ceramic Resonators

For the best clock accuracy, a *quartz crystal* should be used in an oscillator circuit like the one shown in Fig. 8-13. A quartz crystal is a *piezo-electric* device that provides a constant delay between one side of the piece of quartz within the part to the other. The term piezo-electric refers to the property of quartz (and some other compounds) to mechanically deform when a current is applied to it or produce a voltage potential when it is mechanically deformed.

In an oscillator, the quartz crystal will have a voltage applied to one end of it and this will cause the quartz crystal to deform. The rate at which this deformation takes place is known and will cause a voltage potential to be produced at the other end of the quartz crystal after a known delay. This voltage is used as a feedback value to an inverter built into the oscillator circuit. The NPN bipolar transistor-based inverter can be seen in Fig. 8-13.

The circuit in Fig. 8-13 is somewhat ''fiddly'' to build and to get working reliably. There are some formulas that can be used to specify the different resistor, capacitor and inductor values, but, personally, I would never use this circuit in my own applications. This is why I did not put in any component values on the diagram; instead, I would use the inverter-based oscillator shown in Fig. 8-14. In this circuit, instead of understanding a circuit well enough to specify the correct different analog values, you can simply put a crystal across the input and output of a CMOS inverter.

The capacitors and resistors are necessary to ensure that the oscillator runs reliably and there are not any large over- or under-voltage spikes (caused by the operation of the piezo-electric producing its own voltage output). For most MHz range oscillator circuits, 15–33 pF capacitors are

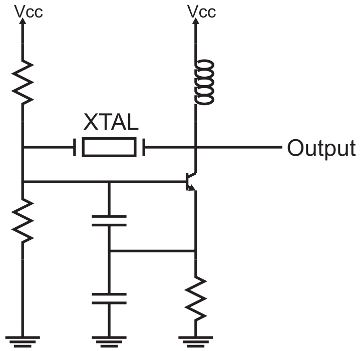

Fig. 8-13. Crystal oscillator circuit.

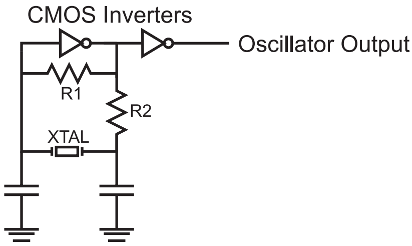

Fig. 8-14. CMOS logic gate crystal oscillator circuit.

adequate, 1–10 MΩ for R1 and 100 to 100 kΩ for R2 is appropriate. You may find that depending on the frequency of the crystal that you choose and how it is wired, you may have to vary these parts.

The second inverter in the circuit is not ‘‘strictly’’ required, but I like to have it in place to ensure the crystal is not ‘‘loaded down’’ by other devices and the operation of the oscillator doesn’t change. Any large loads on the output side of the oscillator’s primary inverter will affect the amount of current/voltage available to the crystal to pass the signal to the other side (and the oscillator’s frequency will drop or the oscillator won’t work at all).

Changing the capacitance on the inverter output side of the primary inverter results in small (1–2%) changes to the output and to help ensure the absolutely correct frequency output is produced a variable capacitor is used in place of the fixed capacitors. I do not feel this is practical and the nominal 0.01% or less error rate of the crystal should be accepted. I realize that there are applications (like digital clocks) where these changes are critical, but for the most part you should not have to ‘‘tune’’ the oscillator for the application.

Crystals work quite well, although there are two drawbacks that you should be aware of. Crystals are relatively expensive parts (especially compared to the RC network relaxation oscillator). You can pay up to $10 for a crystal (although you can pay less than 1$ for common frequencies). In addition, the oscillator is somewhat ‘‘fragile’’ and can be easily damaged by rough handling. A relatively new device that can be used in place of a crystal and does not have these shortcomings is the ‘‘ceramic resonator’’. A ceramic resonator is used in a very similar way to a quartz crystal (Fig. 8-15), but it is usually much less expensive and very rugged. I use ceramic resonators almost exclusively for clocking all my microcontroller applications. Despite the somewhat poorer accuracy of the parts (they are usually accurate to 0.5%), they really are the part of choice for most applications.

Many designers eschew the use of oscillators built from discrete parts as I have shown in this section. These circuits are rarely used because of the difficulty in specifying the correct parts for an application, the cost of the crystals and the potentially large amount of ‘‘real estate’’ that they can take up. Instead, oscillators are usually implemented using some kind of ‘‘canned’’

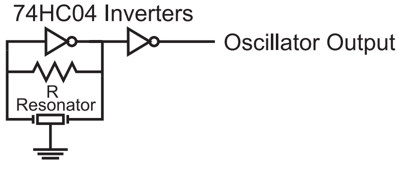

Fig. 8-15. Ceramic resonator oscillator.

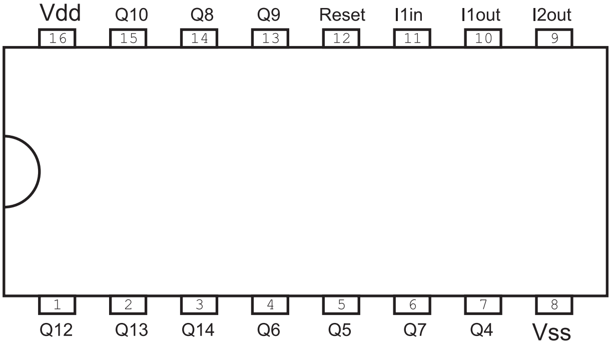

Fig. 8-16. CMOS 4060 chip pinout.

solution. These parts are designed to take up the same "footprint" as an eight or 14 pin "DIP" package and normally have four pins – power, ground, oscillator output and oscillator enable.

One of the most common chips used in digital logic applications is the CMOS 4060 (shown in Fig. 8-16). This chip can be used with the different oscillator types listed in this section and the "divide by" outputs are very handy in many circuits (often eliminating the need for separate counters). The crystal, ceramic resonator and relaxation oscillator circuits that I have shown in this chapter can be used with this part. The "Q4" through "Q13" outputs are divided by counters (i.e. "Q4" is the clock divided by 2 to the 4 or 16 times).

When using the 4060, note that Pin 11 is the input to the inverter used in the oscillator circuits shown in this chapter, Pin 10 is output of the first inverter and input of the second inverter while Pin 9 is the output of the second inverter. If Pin 12 ("Reset") is pulled high, the oscillator is stopped and the counters in the chip are reset.

555 Timer Chip

The 555 timer chip is probably the most versatile non-programmable part I have ever seen. Over the past 40 years, many people have created at least hundreds probably thousands of applications that have used this chip in ways I'm sure the original designer never would have thought possible; the original function of the chip was to provide a regular train of pulses. In this section, I will show how the chip is used in a circuit, along with some of the tricks that can be performed with it.

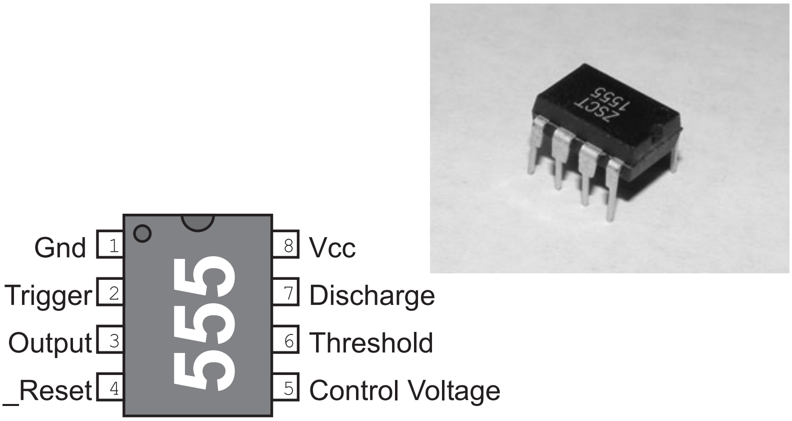

Fig. 8-17. 555 pinout.

In the previous sections, I have shown you the "pinout" of a number of different components – each one of them having a unique form factor. The 555 is usually built into an eight pin "dual in-line package" that is commonly used for chips. In Fig. 8-17, I have put in an "overhead" view of the 555, along with a photograph of an actual 555 chip.

Looking at the labels for each of the pins, most of them do not make a lot of sense. What should jump out at you is the "Gnd" (ground) at Pin 1 and the "Vcc" (positive power) at Pin 8. These two pins are used to provide power for the part; they match the power pins I've presented elsewhere for digital devices elsewhere in the book.

To try and get a better understanding of a chip, one of the first things I do is look for its block diagram and try to understand it. In Fig. 8-18, I have drawn out the block diagram for the 555 timer.

There should be two parts to the block diagram that you should recognize immediately. The first is the transistor at the bottom middle of the diagram. This transistor is wired in an open collector configuration and is acting as a switch that will pass current to ground. The next piece that you should recognize is the voltage divider running along the left side of the block diagram that I have separated out into Fig. 8-19. If you were to work out the voltages at "Vcontrol" and "Vtrig", you would discover that they are at 2/3 Vcc and 1/3 Vcc, respectively. This is actually an important clue as to how the chip works.

One aspect of the 555's voltage divider circuit that you may find confusing is its connection to an outside pin called "Control Voltage". As I have shown in Fig. 8-20, this connection allows the circuit designer to change the voltage

levels of the voltage divider circuit. Rather than "Vcontrol" being 2/3 Vcc, it can now be any value (less than Vcc) that the designer would like. Changing "Vcontrol" also changes "Vtrig" to 1/2 "Vcontrol", as I have shown in Fig. 8-20.

L	L	L
H	L	H
L	H	L
H	H	L

Fig. 8-21. Voltage comparator operation.

The voltages at the "Vcontrol" and "Vtrig" are passed to two triangular boxes with a "+" and "−" along with a funny looking equation. These boxes are representations for voltage "comparators" and, as I have shown in Fig. 8-21, the comparators output a high voltage level when the voltage at the "+" input is greater than the voltage at the "−" input. The 555 uses the two comparators to continuously compare two external voltage levels to "Vcontrol" and "Vtrig" and pass the results to a box labeled "RS flip flop".

The 555's RS flip flop saves an indication of which comparator last passed a high voltage to it. If the comparator connected to the "threshold" pin of the 555 and "Vcontrol" of the voltage divider output a high voltage, then the flip flop will output a high voltage at "_Q", which turns on the transistor at the bottom of the block diagram. If the other comparator passes a high voltage to the "RS flip/flop", then the voltage at "_Q" is driven low and the transistor is turned off. This is a fairly complete explanation of how the 555 works and I'm sure that you are at least as confused as you were when I first showed you the block diagram of the chip. The individual parts are quite easy to understand, but I'm sure you're mystified how they work together.

When I described the operation of the 555 chip, I neglected to take into account the components that would be wired to it. The timing delay that is integral to the operation of the 555 is produced by resistors and capacitors wired in the "RC networks" that I have described earlier in the book. What I didn't go into detail on in the previous sections of the book is that as you change the value of the resistor or capacitor in the circuit, you will change the delay produced by the two components (Fig. 8-22).

In Fig. 8-23, I have drawn a 555 oscillator circuit; when this circuit starts running, the 555 will be an "astable" oscillator with the output toggling,

Fig. 8-22. RC network operation for ranging values of RC.

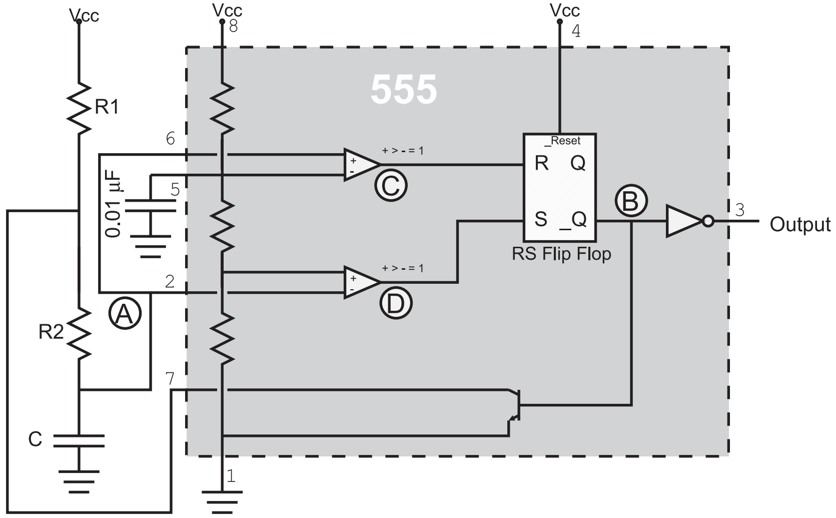

Fig. 8-23. 555 astable oscillator.

according to the values R1, R2 and C. The 555's output times are defined by the formulas:

$$T_{high} = 0.693 \text{ x } C \text{ x } (R1 + R2)$$

$$T_{low} = 0.693 \text{ x } C \text{ x } R2$$

$$\text{Period} = 0.693 \text{ x } C \text{ x } (R1 + 2R2)$$

$$\text{Frequency} = 1.443/(C \text{ x } (R1 + 2R2))$$

When choosing the resistor and component values for working with the 555 timer, you should only use components that are within the ranges listed below:

$$10k \leq R \leq 14M$$

$$100\,pF \leq C \leq 1{,}000\mu F$$

The 0.01 µF capacitor wired to the "control voltage" pin of the 555 (in Fig. 8-23) is used as a "filter" for the internal voltages. This capacitor works very similarly to the logic circuit's decoupling capacitor; if the input voltage changes, the capacitor will absorb or release charge to keep the voltage as even as possible.

To get a better idea of how the 555 timer works as an oscillator, in Fig. 8-23, I labeled the RC voltage ("A"), the RS flip flop output ("B" – which is in the inverted 555 output), the "threshold" comparator voltage

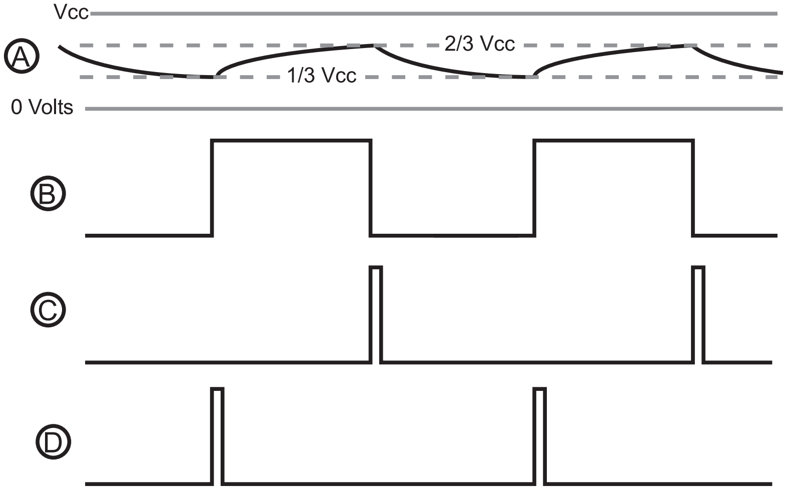

Fig. 8-24. 555 astable operation.

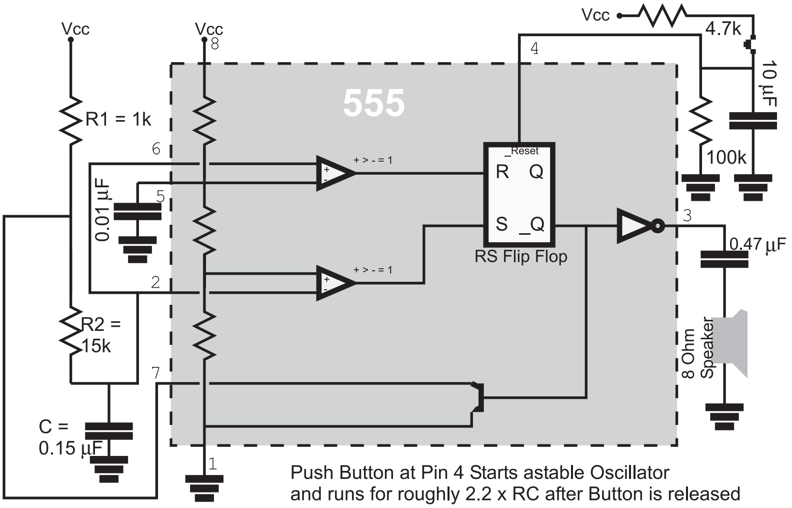
("C") and the "trigger" comparator voltage ("D"). Figure 8-24 shows the waveforms for each of these parts marked in Fig. 8-23, so you can see the changing RC waveform, the output from the two comparators and the action of the RS flip flop.

Before going on, I want to share with you some of the more clever and useful circuits that have been created using the 555 timer. The few I will show in this chapter are just a small fraction of the number that is possible or has already been developed. If you are in a used book store, you should look for a copy of Don Lancaster's "555 Timer Cookbook"; it will really open your eyes to the incredible variety of applications this chip can help implement.

When stretching the envelope and using the 555 timer in a way that it wasn't originally designed for, you generally look at the different input pins and see how they can be given a completely different function. If you wanted to make a circuit that drove out a tone for a set amount of time, you could use two cascaded 555 timers (or a single "556", which consists of two 555 timer chips in a single package) or the circuit shown in Fig. 8-25.

When this circuit is first turned on, the voltage at Pin 4 (the RS flip flop reset pin) is low, stopping the circuit from oscillating. When the momentary on button is pressed, current is passed to the 10 μF capacitor, charging it and driving up the voltage on Pin 4. This happens quite quickly and when Pin 4 reaches the logic threshold to stop holding the RS flip flop reset, then the 555 will start oscillating, driving out a signal that oscillates at 464 times per second.



Push Button at Pin 4 Starts astable Oscillator
and runs for roughly 2.2 x RC after Button is released

Fig. 8-25. 555 tone output.

This tone will stay on as long as the button is pressed and then will continue until the 10 µF capacitor discharges through the 100 k resistor. By varying the values for these two parts, you can vary the length of time the 555 continues to oscillate. Remember the rule of thumb that is used to approximate the time for an RC network, like this one, to discharge:

$$\mathtt{T_{discharge}} = \mathtt{2.2\ x\ R\ x\ C}$$

I take advantage of the ability of the human ear to distinguish between different sounds and categorize them with a circuit design for a continuity tester that you will probably find is a lot more useful than the simple instrument built into your digital multi-meter.

This continuity tester circuit shown in Fig. 8-26, is useful in a variety of different situations. Instead of just driving out a simple tone when an electrical path between the two probes has been found, it provides you with different tones and sounds, based on the resistance between the probes as well as an indication of whether or not a diode is between the probes. Because the circuit is self-powered, you can use it with circuits that are already working, without worrying about having a valid ground connection.

When there is no connection between the leads, the 5.1k resistor is part of the RC network that provides the delay for the 555 timer wired as an astable oscillator. With no connections, you will find that the oscillator outputs a tone that is at about 440 cycles per second (“hertz” or “Hz”). If there is a direct connection (or short circuit) between the two probes the 5.1 resistor is

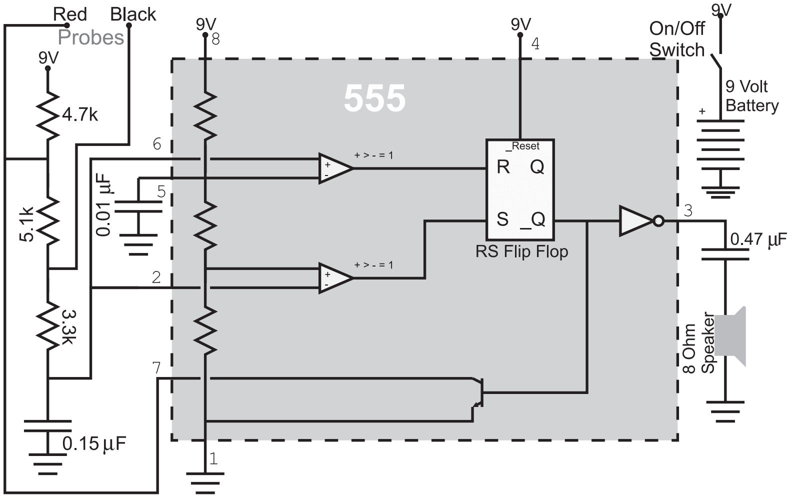


Fig. 8-26. 555 based continuity tester.

not used in the delay and the frequency output is around 880 hertz, there is a full octave difference between the two signals.

What I like about this circuit is that you get a different frequency based on the resistance across the probes – the probe resistance is in parallel with the 5.1 k resistor, changing its frequency and the frequency output from it. This can be useful in finding "almost" short circuits such as a "just touching" connection rather than a hard soldered connection or a "high impedance short", when you expect no connection at all. In addition, try out a diode in a forward biased and reversed bias connection; you will be able to hear a noticeable difference here as well.

Delay Circuits

Another basic function of the 555 is use as a "monostable". In the previous section, I alluded to this function and noted that the 555 could do more than just be part of the "astable" oscillator which will run for ever – the monostable, on the other hand, will only execute once and requires triggering. The monostable is very useful for a variety of different applications and works similarly to digital logic chips that can provide a similar delay. Figure 8-27 shows the 555 wired as a monostable generator and Fig. 8-28 shows the response waveforms to the input pulse.

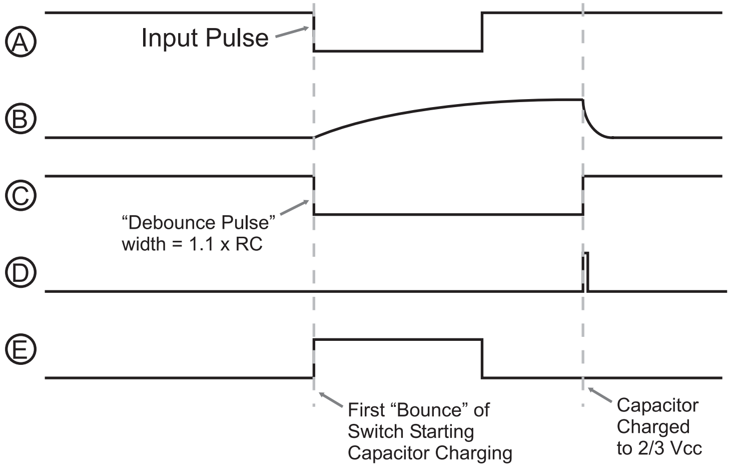

Fig. 8-28. 555 monostable operation waveforms.

When the input goes low, the pulse output from the 555 timer is determined using the formula:

$$T_{\text{pulse}} = 1.1 \times R \times C$$
$$= 1.1 \times 100\,\text{k} \times 10\,\mu\text{F} = 1.1 \text{ seconds}$$

The 555's RS flip flop is initially "reset", and the transistor that passes capacitor charge to ground is turned on. When the input ("A") goes low and the "trigger" input receives a low voltage input, its comparator signal ("E") goes high, changing the state of the RS flip flop (“C”) and changing the state of the output pin. When the RS flip flop state changes again, the transistor is turned off and the capacitor charges through the resistor. The capacitor charges according to the formula:

$$\mathrm{Output} = \mathrm{Vcc} - \mathrm{Vcc} \times e^{-t/RC}$$

until its voltage reaches 2/3 Vcc. When it reaches 2/3 Vcc, the “threshold” comparator (“D”) goes high and the RS flip flop changes state again, changing the value of the output pin (“C”). At this point, the 555 is back to its original state.

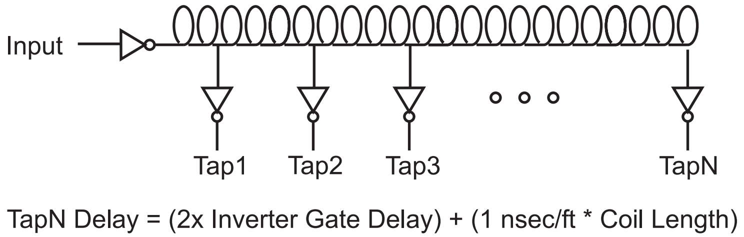
This circuit works quite well except for one point – the input pulse must *always* be shorter than the calculated output pulse. If the input pulse is longer than the calculated output pulse duration, you will find that the output will stay active, but it will pulse periodically. When the capacitor charges to 2/3 Vcc and the input is low down, both of the comparators will be driving a high voltage to the RS flip flop. This is an invalid condition for the RS flip flop and the output from the flip flop is “indeterminate”, resulting in the transistor tying the capacitor to ground periodically. To avoid this behavior, you should always make sure that the length of time for the pulse output from the 555 is longer than the expected input.

Instead of using the 555 timer as a monostable delay generator, there are a number of logic chips that perform the same function using a resistor and capacitor. The 74123 incorporates two monostable delays that are programmed using a resistor and capacitor. The 74123 and other logic family chips have the advantage that the voltage level transitions do not cause as much disruption to the surrounding circuitry.

In some applications, there is a delay that is either more precise, shorter or longer than can be practically created using the RC-controlled monostables that I have presented so far. In the next chapter, I will be introducing you to “counters” which will either count continuously or stop when a specific value has been reached. The counter, driven by one of the oscillators presented in this chapter, is used to produce either a very long or very precise delay.

For shorter delays, there are two methods that you can consider. The first method is to use a “canned” delay line. These components usually consist of an inverting buffer, driving a long copper line. At different points along the line, inverting “taps” are put in place to drive out the signal. Figure 8-29 shows how these components are used.

When you see an actual “delay line” component, you will probably refer to it as a “chip”. I hesitate to do so because I consider a chip to be simply a silicon chip bonded to a “lead frame” and “encapsulated” in some manner. In a delay line component (or “module”), the wire delay is wound in a coil



Input
Tap1
Tap2
Tap3
TapN
TapN Delay = (2x Inverter Gate Delay) + (1 nsec/ft * Coil Length)

Fig. 8-29. Delay circuit.

with the tap inverter inputs soldered to it at different intervals. The actual device requires very high precision mechanical assembly (more than a standard plastic encapsulated chip) and any errors in assembly or encapsulation will result in a useless part.

The wire in the part passes the digital signal to the various taps within the part, with a delay of roughly 1 nanosecond per foot (30 cm) of wire. When you design high-speed applications, this rule of thumb is very important when you are designing high-speed digital electronic circuits. Chances are you will ask that the traces on PCBs are "routed" with 0.1 inch (2.54 mm) precision to ensure that parallel signals all "show up" at the same place at the same time in the high-speed application circuit.

The advantage of the delay line module is that timing delay can be very precise. Custom-made delay line modules are available (the manufacturer solders the taps at specified points in the coil rather than at standard positions), which can be critical in some applications. This high level of assembly/encapsulation precision has a price that you will have to pay. If you can buy a 74LS04 for less than a quarter in single units, you should not be surprised to discover that a delay line module will cost you over $10.00. The delay line provides you with the best control over different delays required in a circuit, but at quite a significant cost. Delay line modules should only be considered if no other options are available to you when you are designing a circuit.

Another method of delaying signals is to take advantage of the natural delays of digital electronic gates and simply "chain" a number of them together to get a needed delay. In Fig. 8-30, I have shown a 20, 40 and 60 nsec delay built out of a 74LS04 TTL chip.

The advantage of this method is that it is quite low cost and reasonable precision can be built into the circuit. When you are designing delays for your applications, you should consult with the technology operational characteristics chart that I provided earlier in the book (see Table 6-2).

Working with different technologies, you should be able to get quite accurate delays quite inexpensively. The disadvantage of this method is that

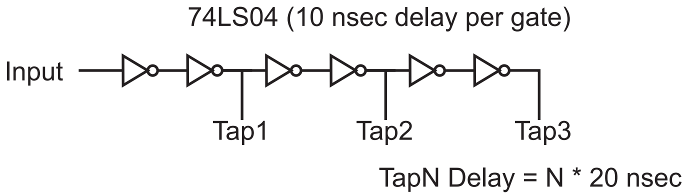


Fig. 8-30. Using logic gates for specific delays.

it can take up a lot of space on a board (at which point the canned delay line may have to be considered).

Quiz

1. An ideal digital electronic clock waveform has:
   (a) A constant period with a 50% duty cycle
   (b) A selectable speed range
   (c) A period that is less than the gate delay of the logic technology being used with it
   (d) A varying period that takes advantage of the operation of the combinatorial circuitry in the sequential circuit
2. Each of the following are important characteristics of astable oscillators except for
   (a) Period
   (b) Jitter
   (c) Duty cycle
   (d) Power required
3. If the R1 or R2 resistor values are less than the product of h_{FE} and Rpu, the NPN transistor relaxation oscillator will:
   (a) Not be reliable and may not start up
   (b) Not work correctly
   (c) Get very hot because the transistors are continuously in saturation
   (d) Produce a perfect, 50% duty cycle output
4. The practice of putting ring oscillators in leftover gates:
   (a) Helps minimize the cost of a digital electronics application
   (b) Helps synchronize other gates in the chip

(c) Should only be done if there is an odd number of inverting gates left in the chip
(d) Should be strenuously discouraged

5. A relaxation oscillator has an R1 value of 10 k, C of 0.1 μF and R2 equal to 1 k. What frequency will it oscillate at?
(a) It won't oscillate
(b) 4.54 kHz
(c) 4.54 MHz
(d) 4.54 Hz

6. What type of application is the relaxation oscillator best suited for?
(a) High power
(b) High cost, not requiring accurate operation
(c) Low cost, high accuracy
(d) Low cost, not requiring accurate operation

7. Canned oscillators are used because:
(a) They are more accurate than discrete component solutions
(b) They are cheaper than discrete oscillator solutions
(c) They are simple and accurate
(d) They are more reliable than discrete component solutions

8. The only type of oscillator that the 4060 cannot implement is:
(a) Ring oscillator
(b) Relaxation oscillator
(c) Crystal/ceramic resonator oscillator
(d) NPN transistor relaxation oscillator

9. Increasing the value of a resistor or capacitor in a 555 astable oscillator will:
(a) Lower its operating frequency
(b) Raise its operating frequency
(c) Increase the output voltage
(d) Lower the output voltage

10. Connecting six 74AS inverters (gate delay 2 ns) end to end will produce a delay circuit that is:
(a) 24 ns
(b) 12 ns
(c) 72 ns
(d) 48 ns

CHAPTER 9

Complex Sequential Circuits

As the saying goes: "You now know enough to be dangerous." You should be fairly comfortable with working with logic functions and equations, have an understanding of electronics and how to interface logic chips (of different families together), understand the basics of memory and have gone through a number of clocking schemes. I'm sure that you now feel you are ready to start bringing these pieces together into some interesting applications. I'm sure that you have some ideas of things you would like to have your hand at designing. Before being set free to wreak havoc on an unsuspecting world, I want to spend some time presenting you with some chips and tools that will make your plans for world domination much easier. In this chapter, I want to go through some of the subsystems that are available in chips that will make your design work easier.

In Chapter 7, I introduced you to the digital clock block diagram shown in Fig. 9-1. There shouldn't be any part of this diagram that is a surprise to you; the "time memory" consists of a number of flip flop registers that are reset

Copyright © 2005 by The McGraw-Hill Companies, Inc. Click here for terms of use.

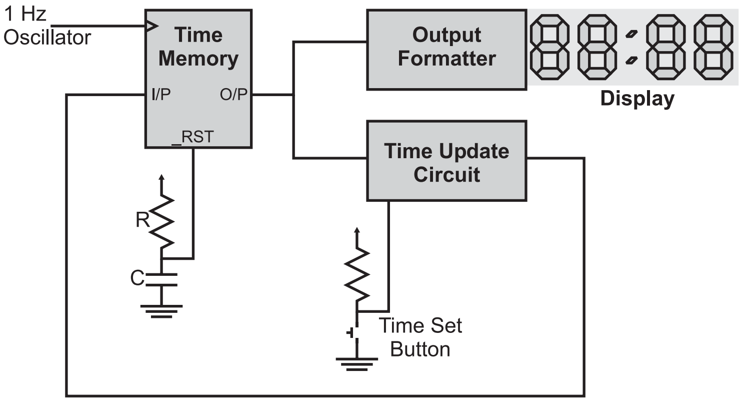

Fig. 9-1. Digital clock block diagram.

upon power up. The "time update circuit" consists of an adder along with logic and a user push button to determine what the *next* time will be. The "output formatter" consists of logic to decode the time memory and display it on a set of LEDs. Finally, the 1 Hz clock can be produced a number of different ways that are covered in the previous chapter.

While I must admit that it would be cool to see a digital clock designed using two input logic gates, I want to point out that there are a number of commonly available chips that provide major subsystems needed for such an endeavor. For the rest of this book I will be focusing on these chips and how they are interconnected to form "real world" applications.

Virtually all of these chips are sequential circuits in their own right; consider a "counter" chip that increments its internal memory devices each time a rising clock edge is received. The counter chip consists of several flip flop bits and combinatorial logic that processes input data, provides the value increment and outputs the data in a specific format. These functions are very similar to that provided by the digital clock in Fig. 9-1.

To show what I mean, consider the sequential circuit block diagram in Fig. 9-2. Superficially, the diagram has a very strong resemblance to Fig. 9-1 because many of the same basic functions and capabilities are required in both instances.

The "state memory" is the current operating state of the chip. The term "state" simply means at what operating point the chip is at. For a counter or other arithmetic function chip, the term "state" probably seems somewhat grandiose, but it is an accurate way of describing the current value in a counter. For a microprocessor, the term "state memory" is almost an understatement, as it includes not only the program counter (which points to the next instruction to execute) but also data and status register information.

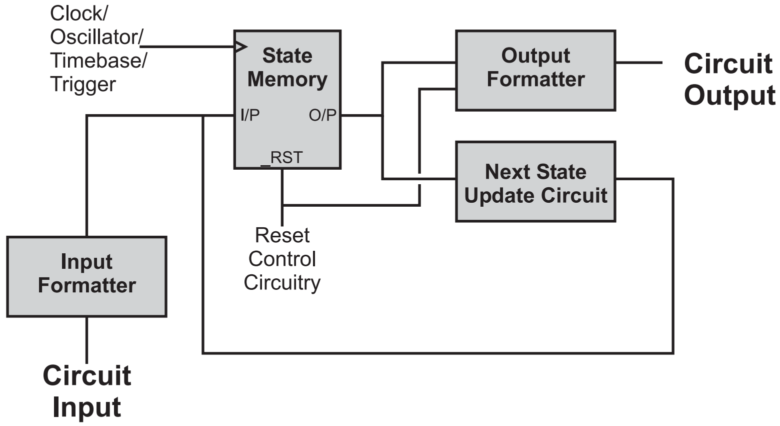

Fig. 9-2. General case sequential circuit.

The state memory can be reset (as shown in the previous chapter) and, more importantly, it is usually the only point in which the clock/oscillator input is received. The philosophy behind most sequential circuits is that the combinatorial logic processing input, output and the next state information, regardless of the circumstances, will be available in time for the next active clock cycle. The term normally used to describe this methodology of design is ‘‘synchronous’’ because a central clock is keeping track of the operations within the chip.

This philosophy is currently under challenge from scientists interested in investigating ‘‘asynchronous’’ digital logic design. This effort involves designing sequential circuits that are not ‘‘paced’’ by a central clock, but the length of time of each operation. For example, moving data from one register to another should take much less time than an instruction which stores data in the main memory. Asynchronous digital logic design holds the promise of faster computers that use much less power because the only active circuitry are the required gates and flip flops of the current time – nothing else needs to be active, nor do other circuits need to be clocked.

The ‘‘next state update circuit’’ and ‘‘input formatter’’ blocks process the current bit data and any relevant input for storage in the state memory. In Fig. 9-1, I combined both of these functions into the ‘‘time update circuit’’ because the only input required for this clock is whether or not the ‘‘time set button’’ is pressed – if it is, then the time update circuit will increment the hours, minutes and seconds stored in the digital clock’s ‘‘time memory’’.

The ‘‘input formatter’’ circuitry can be processing different inputs controlling what the next state is going to be – this is why I link it to the ‘‘next state update circuit’’. For a counter, this information could be the direction the counter executes in or whether or not the counter counts in binary or BCD.

The output formatter converts data into the required output and provides appropriate drivers for the function. Note that I have drawn a link to this box from the ''reset control circuitry'' despite my statement earlier that only the state memory could be reset. The reason for drawing in this link is to indicate that the chip may have tri-state drivers and these are held in a high impedance (''off'') condition while reset is active.

As you work through the material in the rest of the book, try to see how the described chip functions fit in with this model. You might have a better model to work with that makes more sense to you and if this is the case use it. The model that's presented here allows *me* to visualize what is happening in an application, and it would be arrogant of me to assume that it works for everyone else.

Counters

One of the most useful functions that you will use when you develop digital electronic circuits is the counter. The counter is actually a smaller piece of many complex chips, as it provides a basic way of maintaining the current operating state along with a method of progressing to the next one. The basic counter circuit consists of a set of flip flops that drive into and are driven from an adder. A counter circuit is shown in Fig. 9-3.

The use of ''edge triggered'' flip flops is a very important aspect of the circuit shown in Fig. 9-3 and one that you should keep in mind. When the ''counter clock'' changes state, the output value of the adder (which is the D flip flop value plus 1) is presented to the inputs of the D flip flop register bits as the next value to be saved.

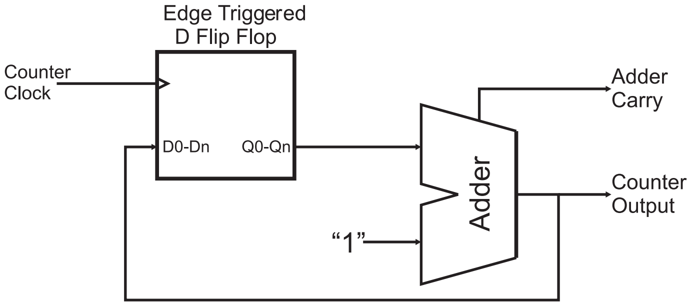

Fig. 9-3. Basic counter circuit.

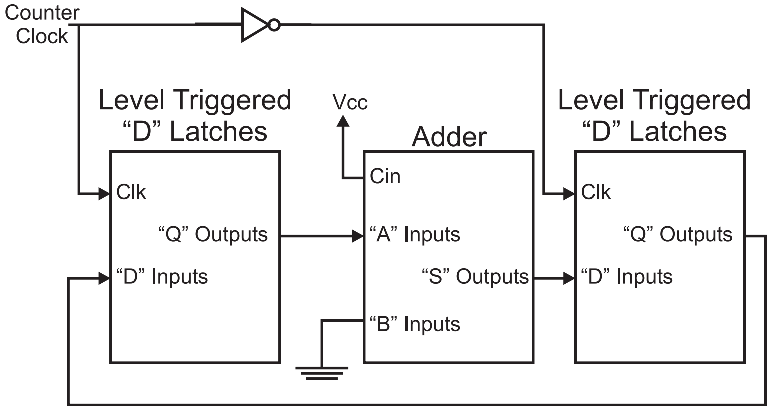

Fig. 9-4. Counter circuit built from level triggered flip flops.

If an edge triggered flip flop register wasn't used in the circuit, then you would have to use latches and design the counter something like the one shown in Fig. 9-4. In this circuit, I have put in two latches, each one "out of phase" with each other. This is to say that when the clock is high, one latch is storing the data while the other is passing through the value presented at its inputs. When the clock changes value, the latches change from passing data to storing and vice versa. This method of implementing a counter is unnecessarily complex and potentially very slow – the extra set of flip flops will slow down the performance of the counter and limit its maximum speed.

The counter circuit of Fig. 9-3 can be built using a 74C174 hex D flip flop and a 74C283 four bit adder circuit. The circuit shown in Fig. 9-5 will demonstrate how the counter works. When the term "floating" is used with respect to pins, it means that the pins are left unconnected.

When you try out this circuit, the first thing that you will probably notice is that when you press the button, the LEDs will not "increment" by 1, but by 2, 3 or even 4. The reason for this is known as "switch bounce". Earlier in the book, I showed a two inverter circuit for eliminating switch bounce, and later I will discuss a number of other strategies for minimizing the problem. For now, if you wire a 0.1 μF tantalum capacitor as shown in Fig. 9-5, you should minimize this problem (although you will probably not eliminate it).

The counter circuit should work well for you. As with the previous projects, a single chip can be used where multiple required. The counter chip that I usually work with is the 74LS193 (Fig. 9-6) which combines a four bit D flip flop register and adder along with the ability to decrement the result. Later in the book, I will show how this chip can be used with others to "cascade" from a 4 bit counter to an 8 and 16 bit counter.

Clock ("DOWN" or "UP")

Fig. 9-6. 74193 counter chip pinout.

The "_Carry" out bit of the 74193 can be passed from one counter to the clock input of another to provide the ability to count more bits, as I show in Fig. 9-7. The carry bit can be thought of as an overflow to the more significant counter, indicating that it should increment its value. If by looking at this circuit you recognize it as being similar to the "ripple" adder presented earlier

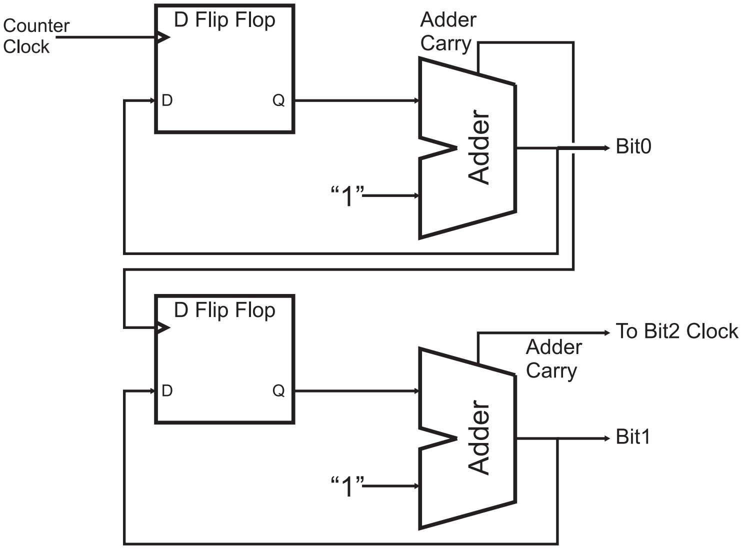

Fig. 9-7. Ripple counter block diagram.

in the book, go to the head of the class. This circuit is known as a ''ripple counter'' and does not have the same high speed as a counter built from look-ahead carry adders.

Along with the 74193, you might want to consider the 74161 counter, which can only count up and changes to the count value must be clocked in (the 74193 allows changes to the count value asynchronously, which is to say without the clock). The 74160 and 74192 chips are identical to the 74161 and 74193, respectively, but only count up to 9 and are known as ''decade'' counters. The 74160 and 74192 are useful in circuits in which the digits 0 through 9 are required for counting.

Shift Registers

Most intersystem (or intercomputer) communications are done serially. This means that a byte of data is sent over a single wire, one bit at a time, with the timing coordinated between the sender and the receiver. So far in this book, if you were to transfer a number of bits at the same time, you would send them in ''parallel'', one connection for each bit. The basis for serial communications is the ''shift register'', which converts a number of ''parallel'' bits into a time-dependent single string of bits and converts these strings of bits back

into a set of parallel bits. Figure 9-8 shows this process with eight parallel data bits being converted into a bit stream and transmitted to a receiver, which "recreates" the eight bits back into their parallel data format.

The differences between serial and parallel data transfers are shown in Fig. 9-9. To send six bits in parallel, a half dozen transmitting "drivers" and an equal number of "receivers" are required. To send six bits serially, just a single driver and receiver is required, but the sending circuit must have a "shift register transmitter" and the receiving circuit must have a "shift register receiver". The parallel data can be sent in the time required for just one bit while the serial data requires enough time to send each of the six bits individually.

It probably looks like transmitting data serially requires a lot of overhead and it slows down the data transfer. There are a number of factors to consider before making this assumption. The first is that most chips are not made out of individual logic gates as the simple chips presented here so far; they are

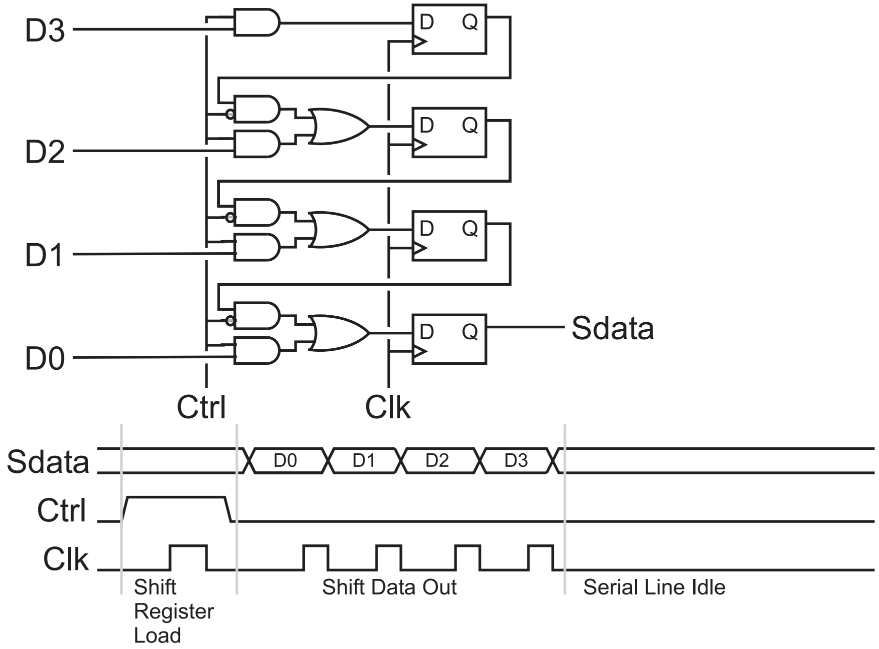

Fig. 9-10. Parallel to serial conversion hardware.

usually very dense circuits consisting of thousands of gates, with the impact of adding serial shift registers being very minimal. Another issue to consider is that it can be very difficult to synchronize all the parallel bits to ''arrive'' at the receiver at the same time in high-speed circuits. Finally, multiple wires can take up a lot of space and be quite expensive; if chips or subsystems could have shift registers built into them, then it often makes sense (both practical and economic) that data be transferred serially.

The circuit that converts the parallel data into the serial stream is quite simple. Figure 9-10 shows a circuit along with a waveform showing how the circuit works. Four bits are first loaded in parallel into a series of four flip flops. These four flip flops can be driven with data either from an external source or from the next significant bit depending on the ''Ctrl'' bit state. If ''Ctrl'' is high, when the ''Clk'' (''clock'') is cycled, the data in the D3:0 bits are stored in the four flip flops. If ''Ctrl'' is low, when ''Clk'' is cycled, each bit is updated with its next significant bit and data is shifted out, least significant bit first.

The process of each bit of data ''passing'' through each of the flip flops is known as ''shifting''. As can be seen in Fig. 9-10 that four data bits are ''shifted'' out on the ''Sdata'' line in ascending order, with the ''Clk'' line specifying when a new bit is to be shifted out. If this method was used to

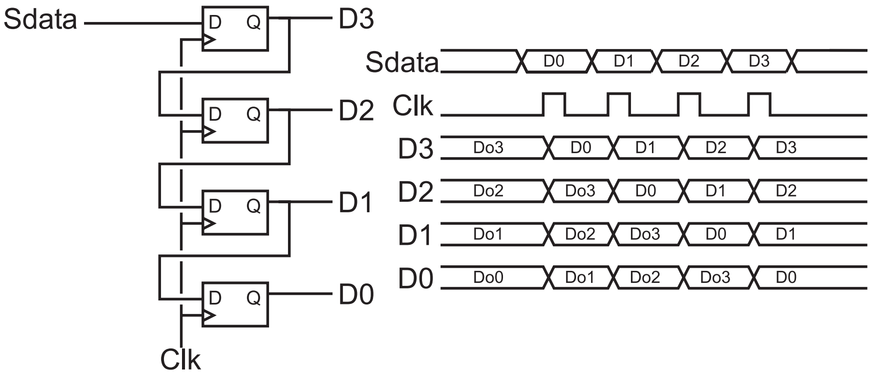

Fig. 9-11. Serial to parallel conversion hardware.

transmit data between two digital devices, it would be known as "synchronous serial data transmission".

Receiving "Sdata" is accomplished by simply using four flip flops wired with their outputs wired to the next input, as I've shown in Fig. 9-11. The same clock that is used to shift out the data from the transmitter should be used to shift in the data in the receiver. Along with the circuit used to shift in the data, I have included a waveform diagram for you to take a look at in Fig. 9-11. One potentially confusing aspect of the waveforms is my use of the "DoX" convention to indicate the previous values within the receiver. These bits will be shifted out in a similar manner as to how the data was shifted in.

There are a number of very common synchronous data protocols that are used in computer systems to provide simple interfaces to common peripherals. These interfaces, which include "Microwire", "SPI" and "I2C", are very easy and relatively fast ways of adding peripherals such as analog to digital converters and external memory to microcontrollers and complete computer systems. In fact, your PC has an I2C processor peripheral bus for controlling power supplies and monitoring the processor's chip temperature.

Linear Feedback Shift Registers

One of the most interesting logic devices you can work with is the "linear feedback shift register" ("LFSR"). It is built from a shift register along with two or more XOR gates modifying the contents of the register as shown in Fig. 9-12. This circuit can be used to "pseudo-randomize" data, encrypt and

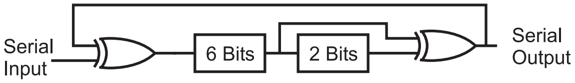

Fig. 9-12. Basic linear feedback shift register (LFSR).

decrypt serial data and provide very good serial data integrity checking. You may have heard the term ''cyclical redundancy check (''CRC'') when applied to data transmission; this is a type of linear feedback shift register. Linear feedback shift registers can also be implemented fairly easily in software with a microcontroller or microprocessor, although it is in hardware where the device is the most efficient.

The simple LFSR illustrated in Fig. 9-12 feeds back bits 5 and 7 of the shift register through XOR gates to the input. This changes the bit values in the shift register according to the formula:

$$\texttt{Bit}_0 = \texttt{Bit}_{\texttt{in}}\ \texttt{XOR}\ (\texttt{Bit}_5\texttt{XOR}\ \texttt{Bit}_7)$$

The LFSR is typically used for three purposes:

1. Creating a ''checksum'' value known as a cyclical redundancy check (CRC), which is a unique value or ''signature'' for a string of bits. Both the transmitter and receiver will pass the data through LFSRs and, at the end of the process, the CRC produced by the transmitter will be compared to the CRC produced by the receiver. If there is a difference in the CRCs, then the receiver will request that the transmitter resend the data.
2. Encrypting a string of bits. LFSRs can be used as an encryption/decryption tool with part of the encryption being the initial value in the LFSR. The value output from the LFSR is dependent on the initial value loaded into the LFSR. Decrypting data is also accomplished by using an LFSR, but configured as the complementary function.
3. Producing ''pseudo-random'' numbers. One of the most challenging computer tasks that you will be given is to come up with a series of random numbers. Computers are designed to be ''deterministic'', which means that what they are doing at any given time can be calculated mathematically. This property is important for most applications (nobody wants a computer to boot differently each time or to have a word processing program that responds randomly to keystrokes), but it is a problem for many applications which rely on the pseudo-random numbers for animated displays or ''lifelike'' responses to user input.

Polynomial Number - LFSR Equation = 1 + x4 + x5 + x6 + x8
Bit Numbering Used for Calculator Simulation

Fig. 9-13. Eight bit LFSR with defining polynomial expression.

In all of these applications, the LFSR is an ideal choice as a solution because it can be built very simply from just a few gates (meaning low cost and fast operation). The LFSR can also be implemented in software, as I will show below.

If you were going to express this LFSR to somebody else, you could send a graphic something like Fig. 9-13, or you could express it in the "polynomial" format like:

$$f(x) = 1 + x^4 + x^5 + x^6 + x^8$$

The polynomial format is the traditional way of expressing how an LFSR works and is used by mathematicians to evaluate an LFSR operation.

There are a few important facts about LFSRs that you should be aware of:

1. The LFSR can *never* have the value zero in it. If it contains zero, then none of the internal bits will ever become set.
2. The ideal LFSR implementation will be able to produce $2^n - 1$ different values. It should be obvious that the one value that cannot be produced is zero.
3. A poorly specified LFSR may have the situation where it ends out with a value of zero.

The operation of a single shift of the 8 bit LFSR in Fig. 9-13 can be modeled using the "C" function:

```
int SingleLFSRShift (intx)

{                                   //Shift the "CurByte" Value

//  with the polynomial 1 + x**4 + x**5 + x**6 + x**8

int LowBit;                         //XOR'd Low Bit
LowBit = x >> 7;                    //“x**8″ Term
LowBit = LowBit ^ (x >> 5);         //“x**6″ Term
LowBit = LowBit ^ (x >> 4);         //“x**5″ Term
LowBit = LowBit ^ ((x >> 3)&1);     //“x**4″ Term
return((x << 1) + LowBit) &0x0FF;   Return shifted 8 Bit value
} //  End SingleLFSRShift
```

Hardware State Machines

The hardware state machine circuit was originally designed to allow designers to create a complex application using a simple, single ROM, a few register bits and some basic logic gates instead of a complex sequential circuit design or a processor-based solution. State machines are not widely used in modern applications because the costs of the parts needed to make up the circuit can very easily exceed that of a microcontroller. Almost ironically, hardware state machines are used as the control mechanism for most modern computer systems because they are fairly easy to design, program and debug. The use of hardware state machines (which are typically referred to as just “state machines”) as the control mechanism for computer processors has given a new importance to the understanding of state machines.

The typical “state machine” is shown in Fig. 9-14. This circuit consists of an ROM (usually EPROM) which has part of its output data fed back as a “state address”. Other address lines are used as circuit inputs and the state machine changes its state address based on these inputs.

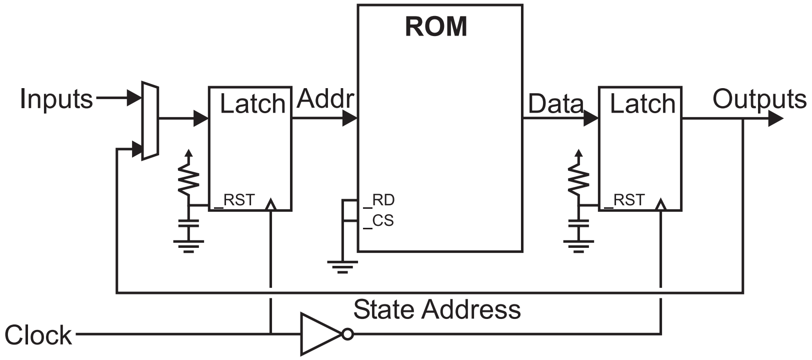

Fig. 9-14. General case hardware state machine.

The clock is used to pass the new address to the ROM and then pass the output from the ROM to the output and input state circuits. The two latches are operated 180° out of phase to prevent ‘‘glitches’’ from the ROM changing state from invalidly affecting any output circuits. A single edge triggered register is not typically used with the state machine because toggling inputs while the ROM is being accessed could result in invalid data being passed into the latches.

As few output bits are used as the ‘‘state address’’ as possible. The reason for this is to maximize the number of outputs and minimize the number of states which have to be programmed. Each state requires two to the number of inputs to function. Each state responds differently according to the inputs it receives.

A typical application for state machines is a traffic light. If a press-button crossing light, as shown in Fig. 9-15, is considered, a state machine circuit, like that shown in Fig. 9-16 could be used.

Fig. 9-16. Traffic light state machine circuit.

In normal operation (which is known as "state 0"), the green light is on and the button is not pressed. If the button is pressed, then execution jumps to state 1, which turns on the yellow light for 5 seconds (states 2, 3, 4 and 5), after which the red light is put on for 26 seconds (states 6–31). If the button is pressed during states 7–31, then execution jumps to state 6 to reset the timer.

B'00100'	x	B'00101'	0	1	0	Yellow LED on
B'00101'	x	B'00110'	0	1	0	Yellow LED on
B'00110'	x	B'00111'	0	1	0	Yellow LED on
B'00111'	x	B'01000'	0	0	1	Red LED on
B'01000'	1	B'01001'	0	0	1	Red LED on
B'01000'	0	B'00111'	0	0	1	Red LED on/reset Ctr
B'01001'	1	B'01010'	0	0	1	Red LED on
B'01001'	0	B'00111'	0	0	1	Red LED on/reset Ctr
⋮		⋮				⋮
B'11111'	1	B'00000'	0	0	1	Return to green
B'11111'	0	B'00111'	0	0	1	Red LED on/reset Ctr

To keep the circuit simple, I want to use an eight bit data bus ROM with six inputs (five state, one button). This means that 2**6 (or 64) states are required in the ROM. These states are listed in Table 9-1. The reset on the input address latch is used to reset the state to 0 on the power up. The button is assumed to be "pressed" if a "0" is returned.

Table 9-1 would then be converted into bits and burned into the ROM. An "x" means both input states have the same result on outputs.

This application is reasonable to code and build, but a problem arises with very complex state machines (ones that require tens of inputs and hundreds of different states). These state machines are normally hard coded into a custom chip rather than built out of discrete parts like I have shown for this application. The reason for placing it within a chip is to give more outputs as well as more states in a custom application. The depth and the width of the data in "real" applications is better suited to custom chips which can have non-custom memories added much more easily than in the situation where only commercial chips are used.

In the example above, I have used a state machine with a one second clock. Obviously in this situation there can be problems (such as the missed input if the button is pressed for less than 1 second and it isn't released after it is pressed). This function makes state machines unattractive for rapidly changing inputs and any kind of sophisticated real-time processing of inputs is simply not economical to do with the state machine. When I say "not economical", I am thinking in terms of the memory and properly programming the many states.

Quiz

1. In the sequential circuit block diagram where is the clock signal passed to?
   (a) To the "state memory" and "output formatter" blocks
   (b) To just the "state memory" block
   (c) To the "input formatter" block
   (d) To the "reset control circuitry" block
2. Asynchronous digital logic design is being pursued because:
   (a) It will result in simpler chip designs
   (b) Circuitry designed under this philosophy will be easier to interface to

(c) The end of performance gains using traditional design methodologies is in sight
(d) It offers faster operations with less power usage

3. Why are edge triggered registers used for counters instead of latches?
(a) It will result in simpler circuit designs
(b) Circuitry designed under this philosophy will be easier to interface to
(c) Less power is required
(d) It offers faster operations with less power usage

4. Ripple counters are:
(a) Always the fastest way to implement counters
(b) Usually more complex electronically than other counter designs
(c) Always the slowest way to implement counters
(d) Similar to ripple adders in operation

5. What are advantages of serial data transmission over parallel data transmission?
(a) Reduced number of drivers and receivers
(b) Faster data transmission
(c) Lower product costs
(d) Higher product quality

6. Where is serial data transmission not used?
(a) The internet
(b) Broadcasting stations to TVs/radios
(c) Keyboard to PC interface
(d) PCI bus interfaces

7. Linear feedback shift registers are built from:
(a) The system architectural drawings
(b) The high-speed circuits to support communications
(c) Shift registers and XOR gates
(d) The basic system serial interface

8. When the value of a linear feedback shift register equals zero:
(a) The operation has completed
(b) Either the initial and input values are zero or there is a problem with the LFSR design
(c) There was an error in encrypting a message
(d) Power has been removed from the circuit

9. Hardware state machines are rarely used except in:
    - (a) Computer processors
    - (b) Military and space applications
    - (c) High-performance custom logic applications
    - (d) Situations where old ROMs are easily available

10. State machines are normally built:
    - (a) Out of discrete chips and ROM chips
    - (b) In complex custom chips
    - (c) On specially designed carrier PCBs
    - (d) With the checksum of the ROM printed on them

CHAPTER 10

Circuit Interfaces

For a sequential digital electronic circuit to be effective, it has to interface with something. This something could be a person or it could be other digital electronic circuits. If you were to look at different interfaces for either case (human or machine), you will discover that as the function of the circuit increases in sophistication, so does the interface. The reasons for this increase in interface complexity can be attributed to an increased amount of data to present as well as an increased number of operating parameters to choose from and select. The challenge is to come up with a way of adding these user and device interfaces simply, effectively and not affect the operation of the central sequential circuit.

Simple logic level switches and individual LEDs for each bit are perfect examples of the types of interfaces that I am talking about; to add these devices to your application, you generally don't require any types of busses nor do you need to have any special communications protocols for communicating with the devices. These interfaces are simple to add and modify to an application.

The problem with simple logic level switches and LEDs connected to each bit is that they cannot be very descriptive; nor are they very efficient methods of transferring data. An eight bit system is quite manageable, but it becomes

Copyright © 2005 by The McGraw-Hill Companies, Inc. Click here for terms of use.

very difficult when there are tens, hundreds or even thousands of bits to control and monitor. Early computers started out using simple switches and lights for input and output, respectively, but quickly outgrew them and began using printers, teletypes and punch cards to get state information from the computer. Today's computer systems have very sophisticated input and output capabilities, requiring the power of a processor that would have been identified as a "supercomputer" 10 years ago or less.

An example of a complex interface that you would be hard pressed (if it were possible at all) to create digital electronics for is the Hitachi 44780 based LCD module (Fig. 10-1). The controller hardware is fairly complex and must be accurately timed. The LCD module works like a "teletype" or a single line TV display – as you write characters to it, a "cursor" will move to the right, to prepare for the next character. The character interface consists of the eight data bits and three I/O pins listed in Table 10-1.

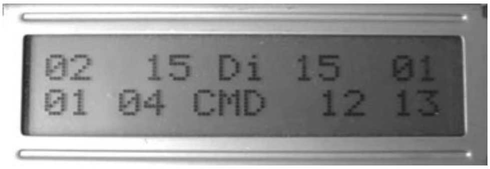

Fig. 10-1. Sample LCD output.

Table 10-1 Hitachi 44780 pin interface.

Pins	Description/function
1	Ground
2	Vcc
3	Contrast voltage
4	"RS" – _instruction/register select
5	"RW" – _write/read select
6	"E" clock
7–14	Data I/O pins

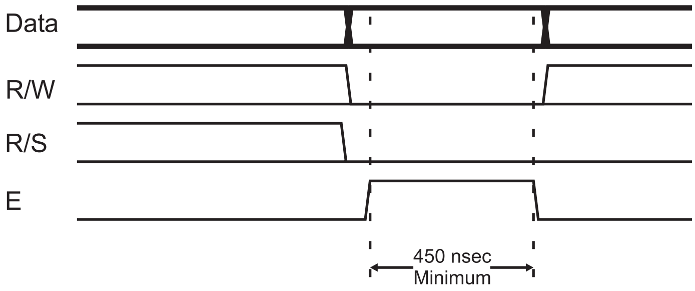

Fig. 10-2. LCD write waveform.

I typically attach a series of pins to the 14 connector pins so that the LCD can be easily mounted on a breadboard. In some LCDs, you may discover that there are 16 connector holes with the extra two holes used for backlighting. Some other LCD modules have two rows of seven or eight pins. For the ease of creating the experiments in this book and wiring them to the breadboard you should just use LCD modules that have a single row of pins.

Wiring the LCD to the hardware is quite straightforward as you will see in the waveform diagram (Fig. 10-2). The only unexpected aspect of the interface circuit is a potentiometer used to set the ‘‘contrast voltage’’ used by the LCD. The potentiometer is wired as a voltage divider, with the contrast voltage pin connected to the wiper of the potentiometer. Depending on the type of LCD that you are using, you will find that the voltage producing the best contrast will either be high or low, depending on the technology used in the LCD.

To communicate with the LCD, you will have to send the data words listed in Table 10-2 via the LCD interface. These bytes are commands that set the operating mode of the LCD or command it to perform some other operation. In Table 10-2, I have listed the different commands, along with the ‘‘RS’’ and ‘‘RW’’ lines that are used to control them. To clock in the command, the ‘‘E’’ bit must have a high value (‘‘1’’) written to it and then a low value (‘‘0’’).

Data displayed on the LCD is, for the most part, ASCII and you can pass ASCII characters directly from the hardware to the LCD. I say that the LCD can display ASCII ‘‘for the most part’’ because you will find that some characters are not supported (such as the backslash, ‘‘\’’) and if you go outside the normal ASCII character limits, you will see Japanese characters on the display. If you were to send a carriage return, line feed or any of the other ASCII terminal command characters, you would discover that they

Table 10-2 Hitachi 44780 based LCD command set.

1	1	D	D	D	D	D	D	D	D	Read Data from LCD at Current Cursor

*, "Don't Care".

result in a strange character being displayed. If you want to provide more "terminal"-like functions to the 44780 based LCD you will have to write them yourself and add them to your application.

Most commands execute in 160 µs or less with the display clear and move cursor to home commands can take up to 5 ms. The initialization process for the LCD is:

1. Wait more than 15 ms after power is applied.
2. Write 0x030 to LCD and wait 5 ms for the instruction to complete.
3. Write 0x030 to LCD and wait 160 µs for instruction to complete.
4. Write 0x030 AGAIN to LCD and wait 160 µs or Poll the Busy Flag.
5. Set the Operating Characteristics of the LCD:

- Write "Set Interface Length"
- Write 0x010 to disable display shifting
- Write 0x001 to clear the display
- Write "Set Cursor Move Direction" setting cursor behavior bits
- Write "Enable Display/Cursor" & "Enable display and optional cursor".

The LCD could be controlled by a state machine, but there would be a significant amount of work to do this (and the state machine would be quite large). Along with the eight bit interface, the LCD can also be controlled by a four bit interface; each character and eight bit instruction is passed in four bit blocks through the D7:4 pins, but this interface would probably be even more difficult to create for the LCD module.

Address and Data Decoders

When you have decided upon the interfaces to your application, you will probably have to determine the best method of selecting which device is active at any time. The method that would make the most sense is to use the same method that a microprocessor uses: output a bit value, selecting the device and one control bit to activate the interface device. Depending on the resources available, the section bits may consist of a number of bits, each one passed to a different interface device, or a binary value, which is decoded into a specific control bit.

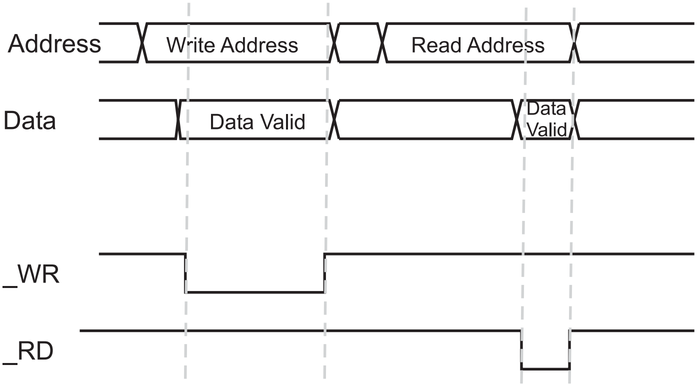

Fig. 10-3. Memory bus reads and writes.

Ideally, the signal being passed to the interface device would look something like Fig. 10-3 – an ‘‘Address’’ value is passed to the device and after a data ‘‘set up’’ time, a Read (‘‘_RD’’) or Write (‘‘_WR’’) line becomes active. A ‘‘Read’’ action polls the interface device and returns the value to the sequential circuit. A ‘‘Write’’ action does the exact opposite: it sends a value from the sequential circuit to the interface device.

You should notice that the timing of the read and write operations are quite a bit different. The short ‘‘Read’’ pulse is indicative of the expected operation of the device being accessed; once it receives the ‘‘Read Address’’ which selects the device, it takes some time to prepare the data before it can be read out. Similarly, when writing data, the _WR line is active for a surprisingly long period of time to allow the interface device to pass the data internally and prepare the interface circuitry to correctly store the data.

The interface read and write operations are good examples of situations where the latches rather than registers are used. When the _RD and _WR signals become active, data should be passed through them as quickly as possible rather than being held on a rising or falling value of the signal edge. For most applications, this need for taking advantage of every possible picosecond of time for data transfer is not needed, but you will find that it’s a good idea to work with a standard design interface that will work in all situations.

Following this philosophy, rather than providing an individual bit to each interface device, how about a binary ‘‘address’’ that can be decoded to an individual address using a ‘‘decoder’’ like the 74139 (Fig. 10-4) that converts a two bit value into four individual active low outputs. The 74139 contains

two “two to four” decoders like the ones shown in Fig. 10-5. Decoders (also known as “demultiplexors”) convert binary values into individual output lines and are primarily used to decode memory addresses to individual chips.

The resulting “interface” is essentially a computer “bus” and will allow you to add standard computer interfaces to your circuit, probably with no modification. You might have been wondering why I went through the effort of providing an interface select function along with the _RD and _WR signals – you may be thinking that a single pin that both selects the device as well as initiate the read or write would be enough; the philosophy of interfacing like in a computer is only so useful. This is true if you are going to only work with custom-designed interfaces, but there are a lot of standard interfaces (including the various ones presented in this chapter) designed for being accessed by computer systems that you will want to take advantage of.

Multi-Segment LEDs

I think you would be hard pressed to find somebody in the industrialized world that has never seen a ‘‘seven-segment’’ LED display (Fig. 10-6) before. It first became popular in the 1970s and is used in almost literally *everything* from digital clocks to car instruments. Seven-segment LEDs can be found virtually everywhere, being used not only in digital watches but also in kitchen appliances, cars, instruments and, of course, in videocassette recorders (VCRs). The flashing ‘‘12:00’’ on a clock or VCR created using seven-segment LEDs is the symbol of a person’s inability to handle the latest in technology.

In Fig. 10-6, I have shown the appearance of the seven-segment LED display – it can be put in the same ‘‘footprint’’ as a 0.300 inch’’ wide 14 pin DIP package, but some of the pins (‘‘N/C’’ for ‘‘no connect’’) are not present. The ‘‘DP’’ LED stands for the ‘‘decimal point’’.

The seven-segment LED display can be wired as either a ‘‘common anode’’ or ‘‘common ‘‘cathode’’; in this experiment we will be using ‘‘common anode’’, wired as shown in Fig. 10-7. For this part, the two ‘‘common’’ pins are connected to all (and occasionally some) of the anodes of the eight LEDs built into the display. This simplifies the wiring you will have to do somewhat and makes working with multiple displays a bit easier, as I will show in a later experiment.

Despite its commonality, the seven-segment LED display is not trivial to work with. There are a number of chips on the market that make the component easier to work with in some applications, but when you are working with your own sequential circuits, you will find that these ‘‘canned’’ functions never quite do what you hope for.

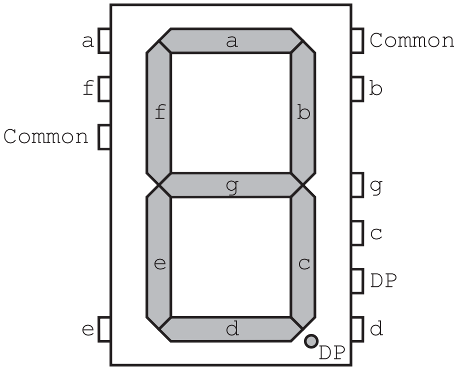

Fig. 10-6. Seven-segment LED display with pinout.

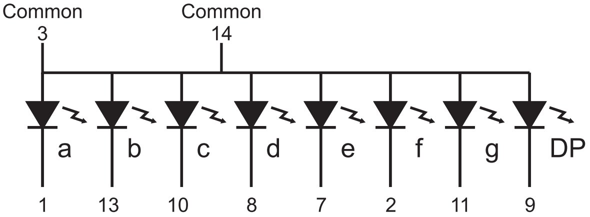

Fig. 10-7. Common anode seven-segment LED display internal wiring.

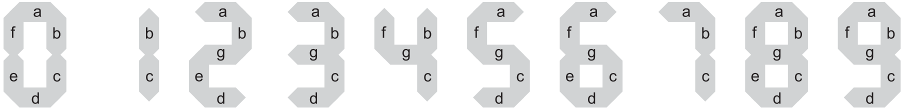

Fig. 10-8. Lit seven-segment LED display elements for different numbers.

As you are probably aware, by turning on each of the different LEDs with their unique values individually, you can create a multiple-digit display. Figure 10.8 shows how by turning on different LED segments, the display can be used to display the 10 numeric characters. Along with the 10 numbers, there are a number of letters that can be displayed, although only a few of them look exactly like the characters they are supposed to represent. If you want to display letters as well as numbers, then you will have to use a LED with more segments – these are available as either 16-segment displays or as matrixes of LEDs that display the character as a multi-dot "font" like on your computer screen.

Each LED in the display can be wired conventionally to control whether or not they are turned on or off. Controlling individual LEDs in a single display is quite easy. It gets quite a bit more difficult when you have to display different values on multiple LED displays. To convert incoming bits to meaningful characters on the display, you will have to pass the bit values through a combinatorial circuit, like the one shown in Table 10-3 for the first four decimal digits.

In Table 10-3 in the "Comments" column, you can see that I have noted any commonalities between different equations and noted that segment "B" is always active for all four digits. I should point out that coming up with the equations for each of the segments is good practice for working with Boolean arithmetic equations, but it is much easier and simpler to buy a seven-segment LED driver. The 7447 chip is commonly used for decoding the incoming bits and driving the LEDs and is an excellent solution when there is

Table 10-3 Seven-segment LED display combinatorial specification for the first four decimal characters.

Segment	"0"	"1"	"2"	"3"	Terms	Comments
A	1		1	1	$(!A0 \cdot !A1) + A1$	Same as "d"
B	1	1	1	1	1	Always on
C	1	1		1	$!A1 + (A0 \cdot A1)$	
D	1		1	1	$(!A0 \cdot\ !A1) + A1$	Same as "a"
E	1		1		$!A0$	
F	1				$(!A0 \cdot !A1)$	Uses AND from "a" & "d'
G			1	1	$A1$	

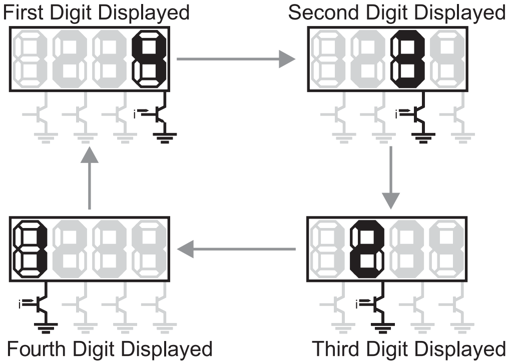

Fig. 10-9. Scanning through four seven-segment LED displays.

only one seven-segment LED display outputting information from the application.

When multiple LED displays are required, instead of providing multiple-digit drivers, a single-digit driver is used and different values are passed to it for different displays very quickly. Figure 10-9 shows a four-digit LED display with each digit having a different value. Each digit is turned on momentarily to display its value and then switched off for the next digit. The eye's visual persistence ignores the flickering if the sequencing is done fast

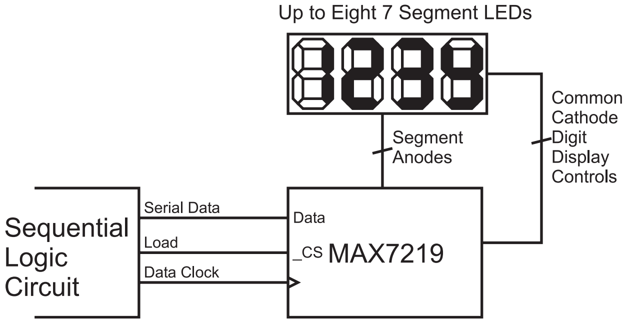

Fig. 10-10. Using a Maxim MAX7219 seven-segment LED controller chip.

enough and it appears that all the digits are on simultaneously, even though they are displaying different values.

As a rule of thumb, each display should be active 50 or more times per second. The slower each display is flashed on and off, the more likely the human eye will pick up the flashing. A flashing multi-character display is not attractive and could cause headaches in some people (especially if the displays are very bright). The time each display is turned on must be as equal as possible. If one display is on for a longer period of time than the others, then it will appear brighter and, conversely, a display active for a shorter period of time will appear dimmer. When working with multiple displays, in order to meet the 50 times per second guideline, you are actually going to have to loop through your individual display action 50 times per second multiplied by the number of displays. So, for a four-digit display, you will have to loop 200 times per second and each digit will be on for 5 ms at a time. There are some chips, such as the very popular Maxim MAX7219 (Fig. 10-10), which can control multiple seven-segment LED displays. This chip takes care of all the driving and timing requirements for the displays; the only catch is that you must shift in the desired value for the display.

Pulse Width Modulation

Despite showing how logic gates and other digital devices are built from simple analog components, they do not handle working with analog voltages very well. There are some circuits that will produce a valid analog (an arbitrary voltage, not just logic ‘‘high’’ and ‘‘low’’) voltage but they do not work very well if the circuit has to drive a high current device. Instead of varying the voltage level to provide varying levels of power, I produce a

string of timed pulses known as a ‘‘pulse width modulated’’ (‘‘PWM’’) signal (Fig. 10-11). A PWM signal is a repeating signal that is ‘‘on’’ for a set period of time that is proportional to the voltage being output. I call the ‘‘on time’’ the ‘‘pulse width’’ in Fig. 10-11 and the ‘‘duty cycle’’ is the percentage of time the ‘‘on time’’ is relative to the PWM signal’s ‘‘period’’.

To output a PWM signal, there are several possible methods. One way is to use two counters that have a common clock. When one counter overflows, it resets itself and the second counter. Until the second counter overflows, the output of the circuit is set to ‘‘1’’. When the second counter overflows, the output of the circuit is reset until the first counter overflows and the process is repeated. Figure 10-12 shows how this type of circuit could be implemented.

This PWM generator circuit uses counters that are reloaded (from the ‘‘Data’’ pins) upon an ‘‘Overflow’’ positive pulse. The ‘‘PWM Period Counter’’ (the ‘‘first counter’’) runs continuously and when it overflows (reaches the final count), it resets and reloads the count value for not only itself but also for the second counter (the ‘‘‘On’’ Period Counter’).

When the PWM Period Counter resets, it ‘‘Sets’’ the S-R flip flop, driving the ‘‘PWM Output’’ high for the start of the PWM signal output. The ‘‘On’’ Period Counter is reset and reloaded by the PWM Period Counter and runs until it overflows. When the ‘‘On’’ Period Counter Overflows, the PWM

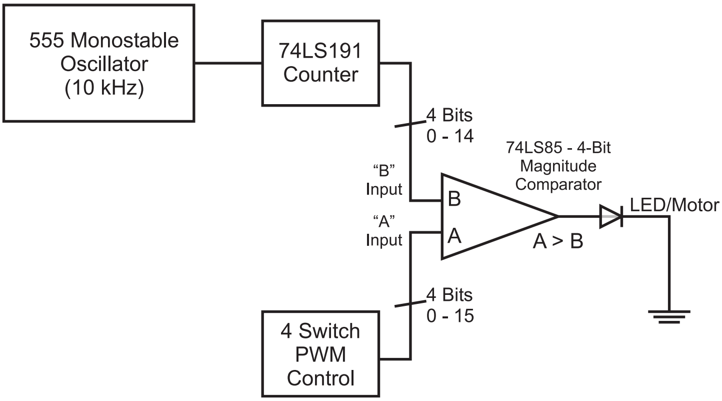

Fig. 10-13. Another PWM generator circuit design block diagram.

Output is halted and it also stops running until the PWM Period Counter reloads it, which resets the "Overflow" output and allows the Counter to drive the "On" Period Counter once more.

Another type of PWM generator is shown in Fig. 10-13. The counter output will be continuously compared against a bit value and when the bit value is greater than the counter value, a "1" will be output. The block diagram for the circuit that I envisioned is shown in Fig. 10-13 and can be built quite easily as I show in this section.

When you study Fig. 10-13, there will probably be one point that won't make sense to you: I show that the counter ranges from 0 to 14 and not 0 to 15, as you would expect for the typical four-bit counter. I wanted the counter to reset itself at 14 rather than 15 so that when the binary values were compared, a 100% duty cycle could be produced as well as a 0% duty cycle by outputting a "1" when the set value was greater than the counter value. If the counter ran from 0 to 15 then the circuit would not be able to produce a PWM with a 100% duty cycle.

To produce the bit range from 0 to 14, I used the 74 × 191 chip counting down and tying the "_LOAD" pin to the "_RIPPLE" pin and driving the inputs to 14. The "_R" ("Ripple" Output) pin becomes active when the chip is "rolling over" from one extreme to another and the "_LD" pin moves the value at the input pins into the counter's latches when it is active. Normally, when a four-bit counter is "rolling over" as it counts down it goes from 0 to 15, but by tying the "_R" pin to the "_LD" (negative active "Load") pin of the 74 × 191, you can load in a new value when the counter reaches 0 and is about to roll over. This feature is ideal for this application as it ensures the count stays in the range of 0 to 14.

Fig. 10-14. Sample PWM generator circuit schematic.

Converting the block diagram to a schematic one is very straightforward (Fig. 10-14) and wiring it onto the PCB's breadboard is tight but not really a challenge (Fig. 10-15). The PWM output value is specified by the four-position DIP switch. I placed 0.01 µF decoupling capacitors on all of the power inputs of each of the chips. These decoupling capacitors are very important when working with the standard (not CMOS) 555 because it can place large transients on the power line.

I used TTL chips (powered by 5 volts from the 78L05 regulator) rather than CMOS chips because I found that it is difficult locating 74C85 chips. An advantage of using TTL instead of CMOS for this circuit was that I could simply pull the comparator inputs to ground without the need of a pull up resistor. If you build this circuit with CMOS chips, make sure that you have 10 k pull up resistors on the DIP switch to ensure a high voltage is passed to the comparator.

Once you have built the circuit, you will find that the LED's brightness will be dependent on the value on the DIP switch. It will be confusing, as the value on the DIP switch will seem to be the opposite to the behavior of the PWM. When all the switches are "on", the LED will be off and, for what seems to be a "large" value, the LED will be dim. When all the switches are "off" the LED will be full on. This confusion is a result of the "on" marking indicating when the switches are closed, not when the signal is a "1" or "high" (which is often extrapolated to being "on") – when the switches

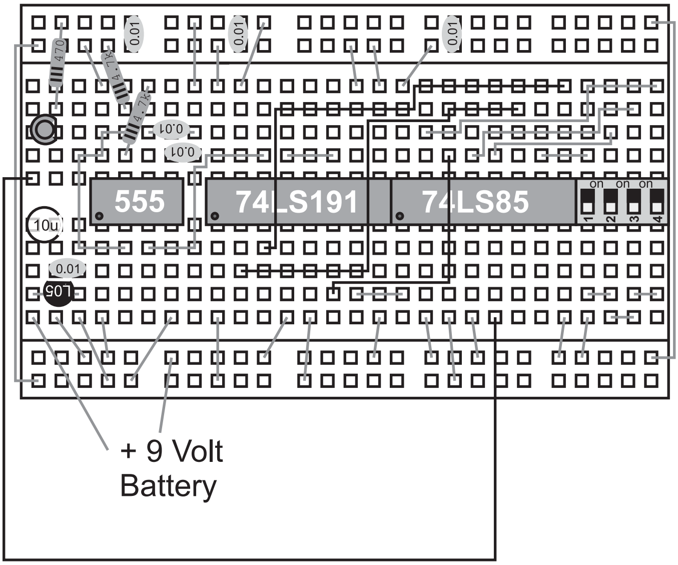

Fig. 10-15. Sample PWM generator circuit wiring diagram.

are closed (“on”), the comparator input is pulled to ground and has the value “0”.

For all PWM circuits (not just the two I’ve shown here), you must remember that the effective frequency is the input clock frequency divided by the counter value. For the example circuit shown here, the 10 kHz signal is divided by 15 (how many cycles the 74LS191 counts before resetting) so the resulting output signal frequency is 667 Hz, which is still faster than the human eye can perceive a flashing LED, but much lower than required for some DC motors. PWMs are commonly used to control the speed of electric motors and if the PWM frequency is within the audible range of human hearing, you will hear a definite “whine” from the motors. The solution to this problem is to either run the PWM at frequencies above human hearing (greater than 18 kHz) or below the range of human hearing (60 Hz or below).

The lower PWM frequencies should not be an issue to produce, but the higher ones can be a challenge, especially if more bits are used in the counter. For example, to create a 20 kHz PWM output signal, you will have to provide a 300 kHz clock for a 15-value PWM and 5.1 MHz for a 255-value PWM! You may find that to get a practical circuit, you will have to find a compromise between the number of bits used in the PWM for the signal level and the speed of the oscillator that is going to be used with it.

An interesting feature of a PWM is how it can save you power. If you were to run the PWM with a 75% duty cycle, what do you think the average power output would be? If you answered 75%, then you didn't go back in the book to look up the power formula. Power is defined by the formula:

$$P = V \times i$$

and substituting in values from Ohm's law, it can be also expressed as:

$$P = V^2/R = i^2 \times R$$

From these formulas, it should be obvious that if the voltage is high only three-quarters of the time, the power dissipated by the device being driven by the PWM is nine-sixteenths or 56% of the total power used by PWMs running with a 100% duty cycle. This means that, along with providing the ability to ''throttle'' direct current devices, a PWM can also result in significant power savings as well.

Finally, you might be confused that I gave you two quite different implementations of the PWM circuit; I did this to show you that there is almost always more than one solution to any problem. I normally recommend that new designers come up with three solutions to a problem before going ahead and implementing *something*. Having three solutions to choose from will allow you to compare features and drawbacks and choose the solution that is best for the application.

Button ''Debouncing''

I consider the issue of debouncing switches and buttons to be one of the most important and vexing problems that you will have to deal with when you are developing applications that work with operator input. Most people think that electrical connections happen instantaneously; you might be surprised to discover that the contacts within a switch actually bounce a few times before the switch makes a constant contact. This is shown in the oscilloscope picture in Fig. 10-16.

Earlier in the book, I showed you a simple method of debouncing a switch input by creating a small memory device from two inverters. A major drawback of this circuit is that it ''backdrives'' the outputs of one of the inverters, but this problem can be eliminated through the use of CMOS inverters and a 10 k current limiting resistor. Even with this fix in place, there is another problem to consider when deciding whether or not to use this circuit – finding double throw push buttons can be difficult. This circuit is well suited for double throw switches but, from the practical difficulty of finding double throw buttons, it becomes impractical.

Fig. 10-17. Simple button debounce circuit.

The debounce circuit that I recommend you use is shown in Fig. 10-17. This circuit consists of a resistor–capacitor network that charges over a given amount of time or discharges quickly through a closed switch or button. Figure 10-18 shows the filtering of the bouncing; it is not perfect, but it is much better than what we started with.

The inverter with the funny symbol in Fig. 10-17 is called a “Schmitt Trigger Input Inverter” and provides an extra measure of filtering of the button input. Schmitt trigger inputs are designed to change state on the rising or falling edge of a signal with “hysteresis”, as shown in Fig. 10-19.

Response with Hysteresis
Logic with Hysteresis Low to High Threshold
Logic with Hysteresis High to Low Threshold
Logic with Hysteresis Built in Ignores "Glitch"

Fig. 10-19. Schmitt trigger input operation.

''Hysteresis'' is the property of the Schmitt trigger inputs in which the threshold point for the rising edge of the signal is different than the falling edge. Looking at Fig. 10-19, you can see that the rising edge threshold is above the ''normal gate voltage threshold'', while the falling edge threshold is less.

These changing threshold values are the reason for the strange symbol on the inverters, indicating Schmitt trigger inputs. Figure 10.20 shows the input versus the gate response on an ''X-Y'' chart. The ''X'' axis is the input voltage with rising voltages to the right and the ''Y'' axis represents the response of the Schmitt trigger input. By following the numbers, you can see the response of the input and that it forms the same symbol that I put on the inverter gates. For comparison, a traditional logic gate does not use this symbol – the response threshold is the same for rising and falling edge signals.

Another method of debouncing button inputs is to use a 555 or monostable circuit. In Fig. 10-21, I show a 555 wired as a monostable, driving out a pulse from a button press. The internal waveforms of the circuit

are shown in Fig. 10-22, which shows that any subsequent bouncing of the button after it makes its first connection are ignored by the circuit as the pulse is being output. If you work out the pulse time from R and C, you'll discover that the pulse time is roughly 1 second in length. This should be long enough for a single button press to be registered and the user to remove his fingers. Obviously, this delay is too long to implement multiple buttons or even any kind of data entry functions in the circuit. To do this, you should consider the next section.

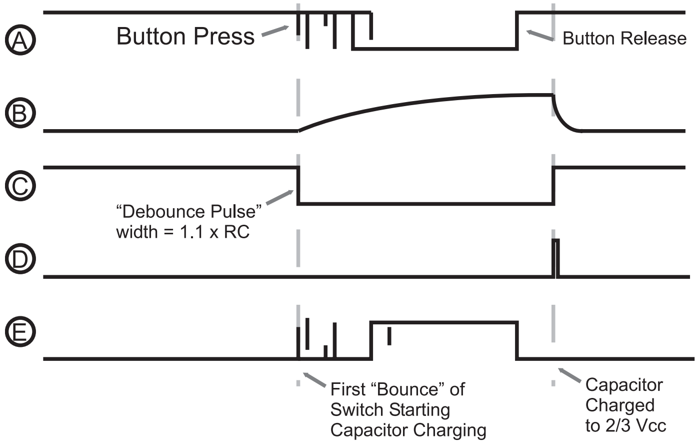

Fig. 10-22. 555 button debounce circuit waveform.

Switch Matrix Keypad Interfacing

As I ended off the previous section, you cannot use simple button debouncing techniques to implement a large number of buttons or even a keyboard for data entry. Just so there's no confusion, I consider a "large number of buttons" to be four or more; providing individual debounce circuits for anything more than a couple of buttons is expensive and time consuming. Along with the cost and time involved, you will also have to come up with some way of prioritizing the button inputs and recognizing non-standard keys like "shift" and "control".

The keys and buttons in PC keyboards and numeric keypads are arranged in "rows" and "columns" and they can be drawn out in such a way that they look like a "matrix". A "momentary on" switch is placed at the intersection of each row and column, as shown in Fig. 10-23. This "switch matrix" provides the ability to "scan" a large number of button inputs with a relatively small number of lines. Your PC's 104/105 keyboard usually has a 22 by 7 matrix connection to a microcontroller, which scans through the keys and reports any key presses using the algorithms presented in this section. Keyboards with a 100 keys or more are an extension of the four-button key matrix shown in Fig. 10-23 and have the same concerns and issues to watch out for.

You probably cannot see immediately how the individual keys or buttons of the switch matrix shown in Fig. 10-23 can be polled, but the operation will probably become clearer when you see the resistors and transistors I've added to the switch matrix in Fig. 10-24.

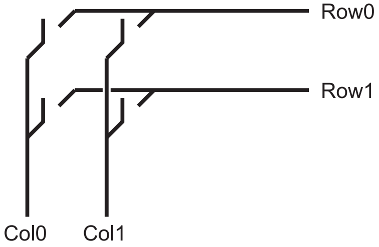

Fig. 10-23. Simple switch matrix.

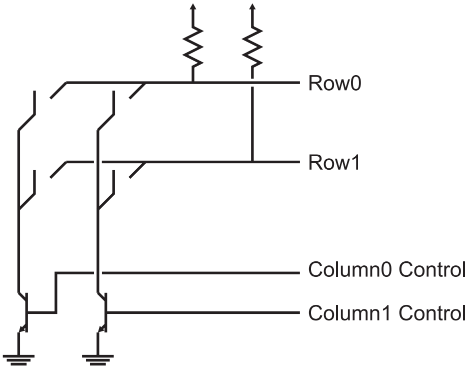

Fig. 10-24. Switch matrix with I/O circuitry.

In this case, by connecting one of the columns to ground, if a switch is closed, the pull down on the row will connect the line to ground. When the row is polled by an I/O pin, a "0" or low voltage will be returned instead of a "1" (which is what will be returned if the switch in the row that is connected to the ground is open due to the pull up on it). To scan the keyboard, the column transistors are turned on, one at a time, and while the column transistor is on and the column is pulled to ground, the rows are compared to a logic level of "0", which would indicate that the button is pressed.

This methodology for handling switch matrix keypad scans I've outlined here probably seems pretty simple. Depending on your familiarity with programming and different microprocessors and microcontrollers, you will probably realize that implementing these functions could be done even simply in assembly language programming or "C". You should also realize that this code would be quite difficult to implement just using logic chips.

To avoid the complexities of trying to develop TTL logic that will carry out the functions described in the pseudo-code presented above, I normally

use the 74C922 keypad decoder chip (Fig. 10-25). This chip can be used to debounce and encode up to 32 buttons (although 16 is the normal maximum) and carries out button debouncing internally as well as keeping track of two currently held-down keys when new keys are pressed. The 74C922 is quite easy to wire to a four by four (16 button) switch matrix keypad, as shown in Fig. 10-26. By "doubling up" rows of sensors of the 74C922, you can add a number of additional keys to the application. In the next section, I will show how this is done to create a 20 button input device (with up to 32 possible).

The two capacitors are used to create a relaxation oscillator within the chip that is used to "scan" through the buttons as well as provide a "debounce" delay count for the application. The two capacitor values are calculated as:

$$\texttt{Cosc} = \texttt{Scan Rate/10 K}$$
$$\texttt{Ckbd} = \texttt{10}^{*}\,\texttt{Cosc}$$

I like a debounce interval of 20 ms: plugging this into the formulas above, I get a value of 2 μF and 20 μF. When I build my own applications, I tend to have a lot of 10 μF (for power filtering) and 1 μF (for MAX232 RS-232 level converters) electrolytic capacitors on hand. I have not found any problems with using these components and I would recommend that you use them as well to avoid having to stock multiple capacitor values for different applications.

Quiz

1. What are ideal sequential circuit interfaces?
   (a) LCDs
   (b) Individual switches and LEDs
   (c) Keyboards
   (d) USB flash disks
2. What is the suggested digital electronics interface to an Hitachi 44780 controlled LCD display?
   (a) Hardware state machine
   (b) Microcontroller
   (c) Sequential circuit
   (d) Combinatorial circuit
3. Is a bus "Read" or "Write" faster?
   (a) Write is faster
   (b) Read is faster
   (c) Using a synchronous clocked circuit, they take the same amount of time
   (d) Read is slower due to the need to retrieve data from the interface device
4. Seven-segment LED displays have a common:
   (a) LED anode or cathode
   (b) Segment pins

- (c) LED drivers built into the package
- (d) Pin interface that is used by all devices, regardless of the number of digits in the package

5. Multiple seven-segment LED displays show different values by using:
   - (a) Linear feedback shift registers that have encoded the bit patterns
   - (b) Turning on each individual digit with its unique value periodically
   - (c) Multiple LED driver circuits that drive the value for its respective digit to the LED display
   - (d) Multiple bits of memory, one for each segment, which are loaded according to the display value

6. For a PWM circuit running its logic at 5 volts and a duty cycle of 67%, what is the "on" voltage level of the output signal?
   - (a) 0.67 volts
   - (b) 5 volts
   - (c) 2/3 volts
   - (d) 3.35 volts

7. The power dissipated by a PWM running with a 20% duty cycle will be what fraction of a 100% duty cycle?
   - (a) 0.04
   - (b) 40%
   - (c) 0.4
   - (d) 400%

8. A 555 monostable with $R = 100\,\text{k}$ and C of $4.7\,\mu\text{F}$ will output a pulse of:
   - (a) Approximately 0.5 s
   - (b) Approximately 4.7 s
   - (c) Approximately 1.1 s
   - (d) Insufficient data given to determine the pulse width

9. Rows and columns in a switch matrix keypad have what connected to them?
   - (a) The rows have a transistor connected to ground and the columns have a capacitor
   - (b) The columns have transistors connected to ground and the rows are left open

(c) The columns are left open and the rows have a transistor connected to ground
(d) The columns have transistors connected to ground and the rows have pull up resistors

10. The 74C922 reads a switch matrix keypad by:
(a) Pulling the columns of a switch matrix keypad to ground and scanning the rows for pulled down bits
(b) Driving a 1 kHz square wave on the rows and polling the columns for the signal
(c) Using an internal microprocessor
(d) Measuring the capacitances of individual lines and looking for changes

11

CHAPTER

Reading Datasheets

I've never understood why college and university courses do not give an introductory course in reading digital electronic device datasheets. Despite how prepared you are for them, you will feel quite overwhelmed the first time you have to look through a number of datasheets trying to find a part that meets your requirements. When I first started working with electronics, datasheets were generally quite poor, with only a few standout companies providing good documentation for their chips. Fortunately, this has changed over the past 10 years, the Internet and the capability of downloading good-quality datasheets being almost a marketing tool to help engineers select the parts they are going to use in their designs.

Personally, I find it more daunting to look at datasheets over the Internet because they are generally encoded as Adobe Acrobat pdfs that take a while to load and you can never flip the pages on the screen as fast as you would like. To make matters worse, it can be very difficult to put multiple datasheets up on a computer display to allow you to compare the features of the different chips. This difficulty gives rise to the most important recommendation that I can make about downloading datasheets from the Internet – print them out! I have several binders of printed out datasheets for parts that I often use. By printing them out, I have immediate access to them and I can

Copyright © 2005 by The McGraw-Hill Companies, Inc. Click here for terms of use.

flip back and forth between pages effortlessly. It is my opinion that documentation shouldn't be "paperless".

The first sheet of the datasheet is usually a one page description of the part. It normally contains:

1. Part number
2. High-level part description
3. Part pinout
4. Common/related/pin compatible parts
5. Important chip features
6. Basic operations truth table

When looking at a datasheet, you should first check out the part number of the datasheet versus what you are interested in. This means that you should be checking not only the numeric code for the device but also the high-level identifier and the technology identifier. For example, if you were looking for a low-power TTL dual input NAND gate and looked up the datasheet based on a web search for "TTL dual input NAND", you could see such diverse part numbers as:

```
74LS00
74C00
54LS00
74W00
74ALS03
```

with the question being: Which is the one that you want?

For these parts the high-level identifier is the "74" or "54". In this book, I have focused on the 74 series of logic – but if you look at "54" series logic you will see that its operation is identical and may decide to go ahead and order the parts. This could be a big problem because "54" series parts are military-grade chips and they tend to cost 10 times that of standard "74" series logic and do not necessarily have the same pinout as "74" series chips. The technology identifier is the letter code between the high-level identifier and the part number. In the list of five chips above, I have presented traditional TTL low-power logic ("LS"), CMOS logic ("C"), advanced Shottkey low power ("ALS") and single gate CMOS ("W"). The danger of not reading the datasheet's part number is that you could end up ordering the wrong part number, resulting in higher than expected costs and lost time looking up and reordering the correct part.

Always read through the datasheet's first page high-level part number description. This can range from a single sentence to four or five bulleted items. Like the part number check, this should just be a filter operation, resulting in you making sure the part will do essentially what you want it to do.

The part pinout is something that is critical to know when you are wiring a circuit. Except for the wiring experiments presented in this book, I have listed only a few part pinouts because a part's pinout may vary between manufacturers of the same part and they may vary according to the packaging type. The part pinout may also change according to packaging technology. It isn't unusual to see a pin through hole (PTH) packaged chip with a specific pinout but its surface mount technology (SMT) sibling having extra pins or different connections to different pin numbers. I'm sure that both of these statements are a bit hard to understand; you might be thinking that the part numbers are standard. I wish I could tell you how many times I have been bitten by these two little traps. Circuit design systems also make assumptions about part pinouts based on the pinouts from specific manufacturers and don't bother checking the pinouts from others.

The important chip features listed on the front page of the datasheet will not list the features of the chip to the lowest possible level, but it will give you some ideas about how the chip works and if there are any issues that could be a problem with you using the chip in your application.

A lot of times you will discover that a part will not have exactly the functions that you want but, by checking the datasheet, it may list related parts that provide a similar function that you can take a look at. Finally, for very simple chips, the front page of the datasheet will present you with truth tables describing the operation of the chip or the different parts of the chip.

The front page of a chip's datasheet can be incredibly useful to you and by spending a few minutes familiarizing yourself with it, you can decide whether or not the chip is appropriate for your application without having to delve into the minutia of the following pages.

Chip Operating Characteristics

An important feature of the datasheet is the "operating characteristics" for the chip. This section of the datasheet explains such operating parameters as:

1. Input pin voltage thresholds and currents
2. Output voltages along with current source and sinking capabilities

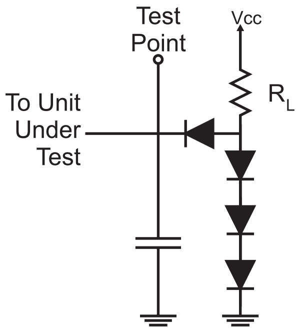

Fig. 11-1. Sample chip test circuit.

3. Gate delay timing
4. Expected input and output pin line impedances
5. Miscellaneous operating information.

Each chip datasheet lists the logic thresholds, along with their characteristics when subjected to different parameters. Often you will see a two-axis graph, with a curve showing the chip characteristic response to the changing input parameters. This part of the drawing should not be difficult to understand but what can be confusing is the small schematic marked as a ‘‘test circuit’’ that often accompanies the graph. An example of such a schematic is shown in Fig. 11-1; it shows the circuit that was connected to the pin while the test was taking place. These test circuits simulate other circuits connected to the chip, helping to ensure that the chip is operating as it would in a typical application.

The output voltage and current characteristics are really a function of the logic technology used and not unique to the individual chip’s pins. If you were to read other datasheets of chips built from the same technology you would discover that the output parameters are the same between the two chips and, by extrapolation, all the chips built from this technology. If you were to search the manufacturer’s web site, you would discover that this information has been published for all parts in the technology family and the information in the chip’s datasheet is really redundant. The reason why the information is repeated in the individual chip’s datasheets is to minimize the amount of cross-checking that you will have to do.

The previous comment could be made about gate delay timing but there is a wrinkle in the specification in the datasheet. Is the quoted ‘‘gate delay’’ for the chip function or for the individual basic technology gate (i.e. the ‘‘NAND’’ gate for TTL)? Normally, the datasheet will list the chip function gate delay instead of the basic technology gate delay because the actual gate delay is probably less than the product of the basic gate delay time multiplied by the number of gates the signal has to pass through.

As you learn more about electronics, you learn that not only do wire connections have resistance but they also have capacitance and impedance. All these factors affect the transmission of data signals and are known by the term "characteristic impedance". Printed circuit boards (PCBs) have a characteristic impedance of 55 Ω (the coax cable that sends signals to your TV has a characteristic impedance of 75 Ω). The input and output pins must be designed to match with the 55 Ω PCB characteristic impedance to ensure that signals pass between pins as efficiently as possible.

All these chip characteristics and any miscellaneous data that the chip manufacturer feels important enough to include should be read through and understood in order to best wire a chip into your application circuit.

IEEE Logic Symbols

When you look at some datasheets, you will see the function of the chip described using a graphical system that is different from the one that I have used in this book. Instead of unique shapes for each gate, they are represented as a rectangular block like the one in Fig. 11-2. These blocks are part of the "IEEE Standard Graphic Symbols for Logic Functions". This standard is often used to describe the operation of a chip instead of the graphical symbols that I have used in the book.

The IEEE gate definition contains a single character to indicate what the function is. Table 11-1 lists the basic characters and their functions. For negated outputs and inputs, the gate pin modifiers presented in Fig. 11-3 are used. Note in Table 11-1, only the four unique gate functions are listed – NAND and NOR gates are represented with the gate modifiers shown in Fig. 11-3.

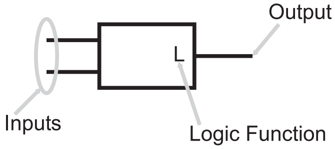

Fig. 11-2. Basic IEEE logic gate symbol.

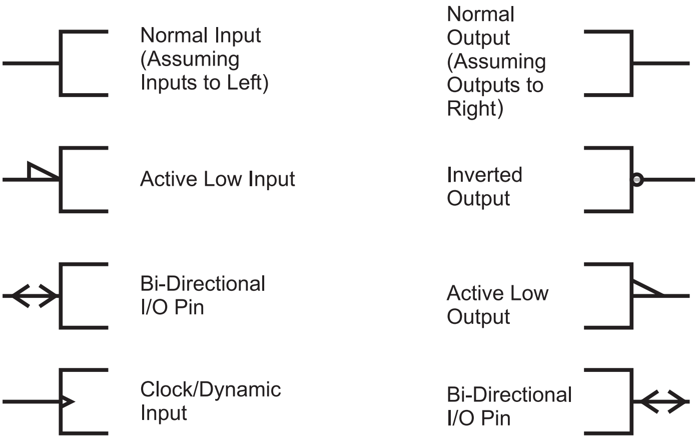
Table 11-1 Four basic IEEE logic functions.

IEEE gate symbol	Gate type
&	AND
|	OR
!	NOT
ˆ	XOR



Normal Input (Assuming Inputs to Left)
Normal Output (Assuming Outputs to Right)
Active Low Input
Inverted Output
Bi-Directional I/O Pin
Active Low Output
Clock/Dynamic Input
Bi-Directional I/O Pin

Fig. 11-3. IEEE logic gate pin modifiers.

For the complete IEEE logic symbol definition, I suggest that you download and printout ANSI/IEEE Std 91a-1991 from:

http://www.ee.ic.ac.uk/pcheung/teaching/ee1_digital/logic symbols.pdf

This document outlines the conventions used to identify each of the different functions used to describe different logic functions in the IEEE standard format. This method of presenting chip functions may seem to be rather difficult to decode when you first see it, but after you've worked with it a while, it will become second nature to you.

Having said this, I would suggest that you avoid working with these symbols until you are very familiar with working with digital electronics. The standard graphic symbols have been well thought out and are immediately recognizable when you are first learning to work with digital electronics and logic gates. The IEEE symbols can be difficult to distinguish when you are first starting out and you can very easily get yourself into trouble if you misread a symbol or forget the purpose of a pin modifier.

Power Usage and Fanouts

An important consideration for selecting a chip is the amount of power dissipated. This information is necessary not only for the individual gate but also for the complete application. The sum of all the power is the total power needed by the application and this value will dictate the power methodology used as well as the cooling requirements for the final product. While not explicitly a correlation, you will find that the more power a logic technology uses, the more external inputs that can be driven (this is the technology's ''fanout'').

When you look at a chip's current (which is related to its power) consumption, remember to look at not only the current required to power the gate but also at maximum input sinking and output sourcing or sinking. These currents should all be added together to get the worst-case power consumed by the chip. I have seen a number of products where the designer expressed the power consumption by what he thought was a ''typical case'' and found out that the actual current consumption is somewhat higher and the specified power supply did not have sufficient margin for the product to work reliably.

Along with the current consumption, the datasheet should also specify the number of input pins the chip's output pins can drive. It is important to note that the number of input pins quoted is the *same technology* as the chip. When you are mixing technology, you will have to understand the input current requirements of the input pins and, as ''a rule of thumb'', make sure that the total current drawn by the input pins does not exceed 50% of the total sinking current capability of the output pin. This will ensure that the logic functions will be at the correct levels regardless of the circumstances.

Actually, I would recommend that for your first applications, you *never* drive more than three inputs from a single output and strive to drive no more than two outputs in the design. Marginal signals due to overloaded output pins are very difficult to recognize from the failure symptoms and difficult to confirm when the problem is suspected.

Quiz

1. What isn't on the first page of the datasheet?
   (a) Part number
   (b) Part pinout
   (c) Chip cost
   (d) Important chip features
2. What is the technology identifier in the part number "74S174"?
   (a) 174
   (b) 74
   (c) 74S
   (d) S
3. What parameter isn't a chip operating characteristic?
   (a) Gate delay timing
   (b) Chip logic function
   (c) Input pin voltage thresholds and currents
   (d) Expected input and output pin line impedances
4. The chip gate delay specification
   (a) Is for ideal conditions
   (b) Is for the basic technology gate delay
   (c) Is for the chip function
   (d) Is for the NAND gate delay
5. IEEE symbols
   (a) Will replace the standard graphical symbols
   (b) Represent negative output functions by placing a symbol on the output pin
   (c) Is used to define all chips
   (d) Are only used for basic logic gates
6. Starting out using IEEE symbols
   (a) Is a bad idea as the symbols are not immediately recognizable
   (b) Is the recommended way to learn about digital electronics
   (c) Will help you design highly optimized digital electronics circuits
   (d) Will encourage you to buy from manufacturers that properly document their products

7. When planning for the current consumption of a product, which current specification should be ignored?
   (a) Standby current
   (b) Output low current sink
   (c) Input low current drain
   (d) None

8. The maximum number of inputs a single output can drive is:
   (a) Determined by the total current drawn by the inputs
   (b) Three in all cases
   (c) The output sink current specification divided by the average input current drain
   (d) Infinite

CHAPTER

12

Computer Processors and Support

I'm sure that you realize that computer processors are really just a great big sequential circuit, but I'm sure that you have no idea where to start understanding how they work. Traditional computer processors are designed using a selection of six or so basic design philosophies that give them different characteristics. In this chapter, I will introduce you to the different issues that have to be confronted in designing computer processors, along with some of the technologies that have been developed to support them.

From a high level, computer processor architects choose from making the processors "RISC" ("Reduced Instruction Set Computers" – pronounced "risk") based or "CISC" ("Complex Instruction Set Computers") based. CISC processors tend to have a large number of instructions, each carrying out a different permutation of the same operation (accessing data directly, through index registers, etc.) with instructions perceived to be useful by the processor's designer while RISC systems minimize the instruction set, but give them as much flexibility and access as much of the memory in the system

Copyright © 2005 by The McGraw-Hill Companies, Inc. Click here for terms of use.

as possible. CISC processors also have the same requirement, but by definition, they are designed to simplify the amount of manipulation that is required by the programmer. Both computer types have their advantages and disadvantages – the RISC tends to be easier to design and executes instructions faster while the CISC tends to be easier to program but may be cumbersome in implementing some functions.

The second option processor designs have came from a competition between Harvard and Princeton universities to come up with a computer architecture that could be used to compute tables of naval artillery shell distances for varying elevations and environmental conditions. Princeton's response was for a computer that had common memory for storing the control program as well as variables and other data structures. It was best known by the chief scientist's name "John Von Neumann". Figure 12-1 is a block diagram of the Princeton architecture. The "Memory Interface Unit" is responsible for arbitrating access to the memory space between reading instructions (based upon the current Program Counter) and passing data back and forth with the processor and its internal registers. In contrast, Harvard's response (Fig. 12-2) was a design that used separate memory banks for program storage, the processor stack and variable RAM. By separating the data and program memories and avoiding the need to arbitrate data movements between them, there was an opportunity for programs to execute faster in Harvard's computer.

It may at first seem that the Memory Interface Unit of the Princeton architecture is a bottleneck between the processor and the variable/RAM space – especially with the requirement for fetching instructions at the same time. In many Princeton architected processors, this is not the case because of the time required to execute an instruction is normally used

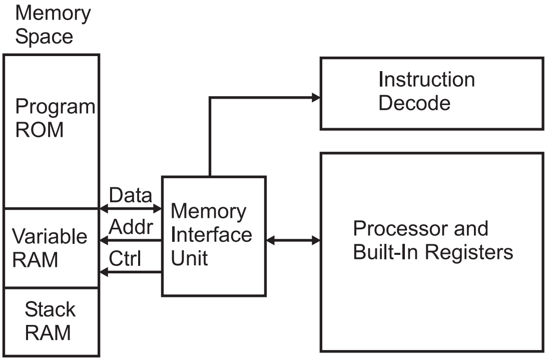


Fig. 12-1. Princeton processor architecture.

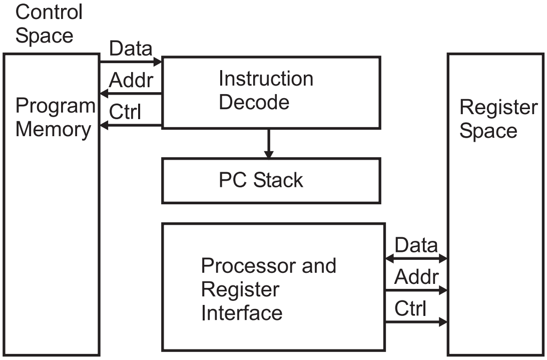

Fig. 12-2. Harvard processor architecture.

to fetch the next instruction (this is known as "pre-fetching"). Other processors (most notably the processor in your PC) have separate program and data "caches" that can be accessed directly while other address accesses are taking place.

The Princeton architecture won the competition because it was better suited to the technology of the time. Using one memory was preferable because of the unreliability of then current electronics (this was before transistors were in widespread general use): a single memory and associated interface would have fewer things that could fail. The Harvard architecture is really best for processor applications that do not process large amounts of memory from different sources (which is what the Von Neumann architecture is best at) and be able to access this small amount of memory very quickly.

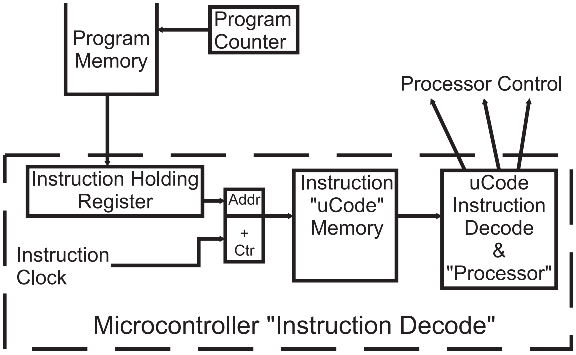
Once the processor's instruction set philosophy and architecture have been decided upon, the design of the processor is then passed to the engineers responsible for implementing the design in silicon. Most of these details are left "under the covers" and do not affect how the application designer interfaces with the application. There is one detail that can have a big effect on how applications execute, and that is whether or not the processor is a "hardcoded" or "microcoded" device. Each processor instruction is in fact a series of instructions that are executed to carry out the instruction. For example, to load the accumulator in a processor, the following steps could be taken:

1. Output Address in Instruction to the Data Memory Address Bus Drivers.
2. Configure Internal Bus for Data Memory value to be stored in Accumulator.
3. Enable Bus Read.

4. Compare Data read in to zero or any other important conditions and set bits in the "STATUS" Register.
5. Disable Bus Read.

A microcoded processor is really a computer processor within a processor. In a microcoded processor, a "state machine" executes each different instruction as the address to a subroutine of instructions. When an instruction is loaded into the "Instruction Holding Register", certain bits of the instruction are used to point to the start of the instruction routine (or microcode) and the "uCode Instruction Decode and Processor" Logic executes the microcode instructions until an "instruction end" is encountered. This is shown in Fig. 12-3.

A "hardwired" processor uses the bit pattern of the instruction to access specific logic gates (possibly unique to the instruction) which are executed as a combinatorial circuit to carry out the instruction. Figure 12-4 shows how



Program Memory

Hardwired "Instruction Decode"

Fig. 12-4. Hardwired processor instruction decode circuitry.

the instruction loaded into the Instruction Holding Register is used to initiate a specific portion of the "Execution Logic" which carries out all the functions of the instruction.

Each of the two methods offers advantages over the other. A microcoded processor is usually simpler than a hardwired one to design and can be implemented faster with less chance of having problems at specific conditions. If problems are found, revised "steppings" of the silicon can be made with a relatively small amount of design effort. The hardwired processor tends to execute instructions much faster but is much harder to modify.

IEEE754 Floating Point Numbers

When I introduced binary numbers earlier in the book, I discussed binary integers, but I did not discuss how binary "real" numbers were produced or how they were manipulated in workstation processors. It should not be a surprise to discover that binary floating point numbers are analogous to decimal floating point numbers.

For example, if you were going to convert decimal 7.80 to binary, you would first convert the value equal to or greater than one to binary. Decimal 7 becomes B'0111', leaving decimal 0.80 to convert. This is accomplished by knowing that decimal fraction digits are multiplied by *negative* exponents of the base 10. The same methodology can be used for binary numbers.

To convert decimal 0.80 to a binary fraction, I will start with the exponent "−1" which is equal to 0.5 decimal and test to see if it can be removed from the fraction. Since it can, my binary number becomes B'0111.1' with a remainder of 0.30. Going to the next negative exponent ("−2"), I discover that I can subtract this value, giving me the binary value B'0111.11'. Continuing this on for another four bits, the binary value is B'0111.110011'. It's interesting to see that the binary number is irrational; the bit pattern will change the smaller the fraction that is calculated even though the decimal number ends at the first digit after the decimal point.

This method can be expressed as the "C" function, which converts the floating point number to a binary string:

```
BinaryFraction(float Value, char* BinaryValue)
{                            // Convert the Floating Point Value to
                              //  a string pointed to by BinaryValue
int i, k;
int j = 0;
      BinaryValue(j + +) = `B´;      BinaryValue(j + +) = `\´´;
                                            // Initialie Binary String
    for(i = 0;  (2<<i) < = Value;  i + +);
                                            //Find Most Significant Bit
                                             // of Value´s Integer Value
    for (; i ! = −1;  i − −)
      if ((Value − (2<<i))> = 0)
         {                                     // Take Away Binary Value
        Value = Value − (2<<i);
          BinaryValue (j + +) = `1´;
        } else                                // Can´t take anything away
        BinaryValue (j + +) = `0´;
          BinaryValue (j + +) = `.´;    // Find fractional value
                                                          // to 4 digits
    for (I = 1, k = 0;  k<4;  i + +, k + +)
      if (Value − (1 / (2<<i)) > = 0)
      {                                 // Can take away binary fraction
        Value = Value − (1 / (2<<i));
        BinaryValue (j + +) = `1´;
      } else
        BinaryValue(j + +) = `0´;
    BinaryValue(j + +) = `\´´;    //Close Binary String
    BinaryValue(j + +) = `\0´;
} // End BinaryFraction
```

This operation can be performed within high-performance processors (like the Intel Pentium), but instead of producing a string of characters representing binary data, they generally put them into the IEEE754 format, which stores the floating binary value in a format which is similar to that of "Scientific Notation":

(Sign) Mantissa × 2** (Exponent Sign) Exponent

The "Mantissa" is multiplied by the signed exponent to get values less than or greater than one.

Table 12-1 IEEE754 data sizes.

Data format	Data range	Data size
Long word	+/− 9.2(10**18)	8 Bytes
Packed BCD	+/− 10**17	8 Bytes
Single precision real	+/− 10**38 to +/− 10**−38	4 Bytes
Double precision real	+/− 10**308 to +/− 10**−308	8 Bytes
Extended precision real	+/− 10**4932 to +/− 10**−4932	10 Bytes

Table 12-1 lists the data formats supported by the Intel Pentium. These different formats give you a lot of flexibility to work with a wide range of numbers in different applications. All the number formats can be processed together, with the final result being in the most accurate format (i.e. a “word” and “single precision” combined together will have a result as a single precision number).

Memory Types

A number of different memory types are currently available. In this introduction, I will first show you three different technologies and discuss where (and why) they are used in a computer system. The boot up, non-volatile memory used in a computer system is based on ultraviolet light “Erasable PROM” (“EPROM”) program memory (Fig. 12-5) and was first introduced in the late 1960s. An EPROM memory cell consists of a transistor

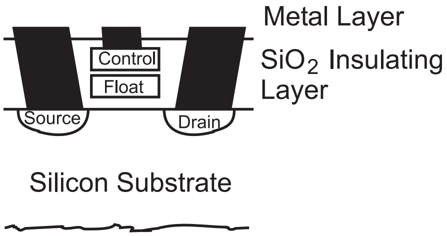

Fig. 12-5. MOSFET EPROM memory cell.

that can be set to be always ‘‘on’’ or ‘‘off’’. Figure 12-5 shows the side view of the EPROM transistor.

The EPROM transistor is a MOSFET-like transistor with a ‘‘floating’’ gate surrounded by silicon dioxide above the substrate of the device. ‘‘Silicon dioxide’’ is best known as ‘‘glass’’ and is a very good insulator. To program the floating gate, the ‘‘Control’’ gate above the floating gate is raised to a high enough voltage potential to have the silicon dioxide surrounding it to ‘‘break down’’ and allow a charge to pass into the floating gate. With a charge in the floating gate, the transistor is turned ‘‘on’’ at all times, until the charge escapes (which will take a very long time that is usually measured in tens of years).

An improvement over UV erasable EPROM technology is ‘‘Electrically Erasable PROM’’ (‘‘EEPROM’’). This non-volatile memory is built with the same technology as EPROM, but the floating gate’s charge can be removed by circuits on the chip and no UV light is required. There are two types of EEPROM available. The first type is simply known as ‘‘EEPROM’’ and allows each bit (and byte) in the program memory array to be reprogrammed without affecting any other cells in the array. This type of memory first became available in the early 1980s.

In the late 1980s, Intel introduced a modification to EEPROM that was called ‘‘Flash’’. The difference between Flash and EEPROM is Flash’s use of a bussed circuit for erasing the cells’ floating gates rather than making each cell independent. This reduced the cost of the EEPROM memory and speeded up the time required to program a device (rather than having to erase each cell in the EEPROM individually, in Flash the erase cycle, which takes as long for one byte, erases all the memory in the array).

For high-speed storage, data is saved in ‘‘Static Random Access Memory’’ (‘‘SRAM’’) which will retain the current contents as long as power is applied to it and is known as ‘‘volatile’’ memory. This is in contrast to the ‘‘EPROM’’ or Flash, which does not loose its contents when power is taken away but cannot have its contents changed as easily as ‘‘SRAM’’. Each bit in a SRAM memory array is made up of the six transistor memory cell, as shown in Fig. 12-6. This memory cell will stay in one state until the ‘‘Write Enable’’ transistor is enabled and the write data is used to set the state of the SRAM cell.

The SRAM cell could be modeled as the two inverters shown in Fig. 12-7. Once a value has been set in the inverters’ feedback loop it will stay there until changed. Reading data is accomplished by asserting the read enable line and inverting the value output (because the ‘‘read’’ side contains the inverted ‘‘write’’ side’s data). The driver to the SRAM cell must be able to ‘‘overpower’’ the output of the inverter in order for it to change state.

The outputs of the inverters are usually current limited to avoid any backdriving concerns.

Large, inexpensive and reasonably high-speed memory can be built from "Dynamic Random Access Memory" ("DRAM") cells. You may have heard the term "Single Transistor Memory Cells" for descriptions of DRAM and that's actually a pretty good description of each cell, which is shown in Fig. 12-8.

In DRAM memory cell, the transistor is used as a switch to allow a charge to be moved into or out of the capacitor. For a write, the transistor is turned on and a charge is either pushed into or pulled out of the capacitor. When the transistor is turned off, the charge is trapped in the capacitor and cannot change until the transistor is turned on again.

A DRAM read is accomplished by turning on the transistor and any charge that is in the capacitor will leak out and will be detected and amplified by a "Sense Amplifier". The "Sense Amp" is a metastable flip flop that will be set to the state of the capacitor when the transistor switch is closed. Before the transistor is turned on when writing to the cell, the sense amp will be set to a specific state to load the correct charge into the capacitor.

In a DRAM memory chip, the cells are arranged in rows and columns, as shown in Fig. 12-9. To address each cell within the chip, a row/column address for the element in the array has to be provided. Usually, to save pins on the DRAM chips, the row and column address lines are shared (multiplexed) together so that during a read or a write, first the "Row" is selected and then the "Column".

The row is selected first so that if a write is taking place the sense amp for the row can be set to the specific value. All the other sense amps are set in their metastable state. When the Column address is latched in, the transistors for the array row are turned on. Next, when the row address is available, the "Input"/"Output Control" transistor is turned on, then the read/write takes

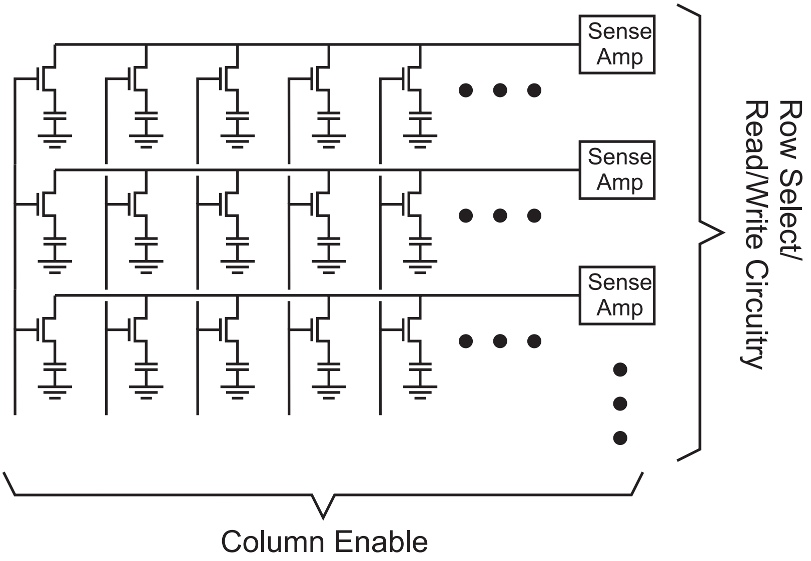

Fig. 12-9. DRAM cell array.

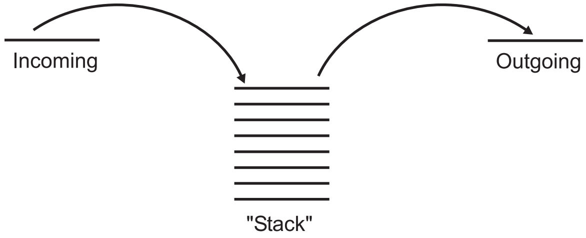

Fig. 12-10. Data stack operation.

place. For the cells not being written to, the sense amps will not only read what the charge is in the capacitor but will also ‘‘refresh’’ it as well.

This is a very good thing in DRAM because the capacitor is actually a MOS transistor built into the chip, acting as a capacitor. Over time, any charge in this capacitor will leak away into the silicon substrate. By periodically ‘‘refreshing’’ the charge by performing a read (which will cause the sense amps to amplify the charge), the contents of the memory will never be lost.

Refreshing is typically done by enabling all the transistors in a column (without first specifying a row) and letting the sense amps do their thing. A read of an incrementing column address is usually implemented in the DRAM support hardware and is known as a ‘‘CAS (‘‘Column Address Strobe’’) Only Refresh’’. In the original PC, 5% of the processor bandwidth was lost due to DRAM refresh requirements. To overcome these potential deficiencies, PC designers have come up with a few hardware features.

Along with being arranged as simple, single-dimensional arrays of data, memory can also be built into ‘‘stacks’’ (Fig. 12-10). Processor stacks are a simple and fast way of saving data during program execution. Stacks save data in a processor the same way you save papers on your desk and is known as ‘‘last in/first out’’ (‘‘LIFO’’) memory. As you are working, the work piles up in front of you and you do the task that is at the top of the pile.

Power Supplies

It is surprising to many people that you can add a simple voltage regulator to power your projects for just a few dollars; cheaper than a set of rechargeable batteries. Voltage regulators, powered by an AC/DC ‘‘Wall wart’’ power converter, will convert one DC voltage to another that can be used by the electronics in your circuit and, more importantly, will be tolerant of changes in the AC supply and the current load. In this section, I will introduce you to some simple power supply circuits that have the following characteristics:

1. They are safe for their users and designers.
2. They are relatively efficient in terms of the amount of power that is lost converting voltage levels.
3. They provide very accurate voltage levels, independent of the voltage input or the current required by the application.
4. They are inexpensive.
5. Their design can be optimized for the application that they are providing power for.
6. These supplies source up to 1 amp of current.

The power supply ideas presented here are very appropriate for the simple circuits discussed in this book; the 250 watt power supply used for your PC requires methodologies and circuits for producing this much power that are quite a bit different than what is required for the simple power supplies presented here. Advanced degrees are normally required for properly designing high current power supplies that work at high efficiencies.

There are some semiconductor-based circuits, like Zener diode power supplies (Fig. 12-11) that do lend themselves to being modeled using water analogs. The Zener diode power supply works as a shunt regulator – applying a specified amount of current to a circuit at a rated voltage and shunting the rest away as wasted power.

When the term "shunt" is used, it is simply saying that excess voltage and current is turned away from the circuit. This concept can be illustrated with a water pressure regulator created from a catch basin with a hole at the bottom; water coming out of the hole is at a pressure which is determined by the depth of water in the basin. To maintain this depth (and bottom pressure), even though water is being drawn from the hole at the bottom, "source" water is continually poured into the basin. More water is pouring in than is expected to exit through the hole in the bottom, with the excess leaking out over the side. This is exactly how the Zener diode works, except

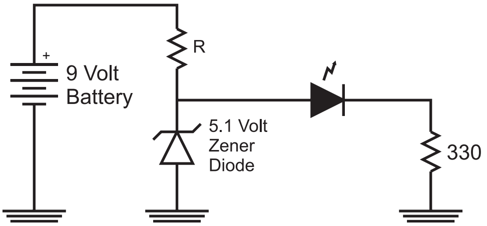

Fig. 12-11. Zener 5.1 volt regulated power supply to LED.

that extra current does not "leak out over the side" but is passed (or "shunted") through the diode. The diode itself is expected to be reverse biased when it is wired into the circuit and it will pass current through it to maintain a set voltage level at its anode (positive terminal). This property is known as "breakdown" and it is not unique to the Zener diode. All diodes will "breakdown" when a high enough reverse bias voltage is applied to them. The breakdown voltage for a Zener diode is usually specified to be in the range of 1.5–25 volts where the breakdown voltage for a typical diode (say the 1N4148/1N914 that I usually use) is 75–100 volts.

Specifying a Zener diode for use as a power supply in an application isn't very difficult but it will require you to understand what your incoming power specifications are as well as what the required current is for the circuit being powered. The powered circuit's voltage should be the same as the rating of the Zener diode. For 5 volt circuits, I use a Zener diode rated at 5.1 volts. Specifying the resistor that is to be used with the Zener diode as well as the Zener diode's power rating can be somewhat complex. Care must be taken to ensure that the circuit has enough current to be powered in all circumstances, including if the input power "sags" (if it is powered by a battery that is discharging). To do this, some kind of "margins" must be designed into the circuit.

For this experiment, I would like to use a 5.1 volt Zener diode to act as a power supply for a LED circuit requiring approximately 10 mA to light the LED. The circuit is shown in Fig. 12-11 and, before it can be assembled, the value for the Zener diode's current limiting resistor "R" must be determined. For a Zener diode power supply to be 100% efficient in terms of current (no current is shunted through the Zener diode), "R" must be chosen so that the voltage drop through it will allow the same amount of current as the powered circuit uses to pass through it. In this application, I am going to assume that the LED has a 2 volt drop, so using the basic electrical formulas, I can determine the current through the LED:

$$\begin{aligned} i &= V/R \\ &= (5.1\,V - 2\,V)/330\,\Omega \\ &= 9.39\text{ mA} \end{aligned}$$

Assuming that the battery produces an even 9 V, the value of R can be calculated:

$$\begin{aligned} R &= V/i \\ &= (9\,V - 5.1\,V)/9.39\text{ mA} \\ &= 415\,\Omega \end{aligned}$$

There are no standard 415 Ω resistors available, but I can make a 420 Ω resistor using a 200 Ω and a 220 Ω in series. This will result in a current of 9.29 mA (a difference of about 1% from the targeted value).

When I described the Zener diode regulator as acting like a basin of water in which the unused current was simply lost, I'm sure that many people grimaced because they knew of devices which are much better at regulating fluid pressure. If this book was written in the 1980s (or earlier) just about everybody would know about the commonly used fluid regulator that is used in older cars called a carburetor (Fig. 12-12). Virtually all cars built in the past 15 years have utilized some form of computer-controlled "fuel injection" which relies on active, rather than passive, control of the fuel being passed to the engine.

The carburetor is a very clever device that only provides fuel on demand. In Fig. 12-12, I have drawn the situation where no fuel is being drawn from the carburetor – a "float" is connected to a simple valve that closes when the fuel in the bowl that the float is in is full. When fuel is drawn from the bowl, the fuel level within the bowl drops (along with the float) and the valve opens, allowing more fuel into the bowl (Fig. 12-13). The carburetor is quite efficient and very simple in operation.

The carburetor acts as a regulator, just providing the volume of fuel (current) as required and the shallow bowl will result in lower pressure (pressure regulation) than what was available from the high-pressure source (the fuel pump). An electrical version of the carburetor would look

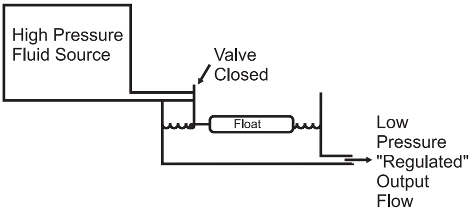

Fig. 12-12. Carburetor with no fluid being drawn from the bowl.

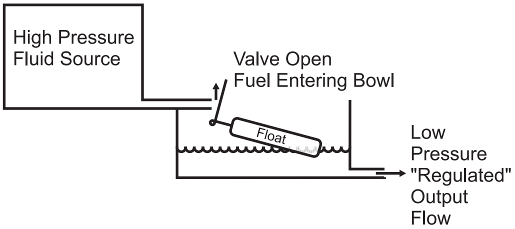

Fig. 12-13. Carburetor in operation.

like Fig. 12-14; current from the high voltage source is switched through a PNP bipolar transistor, with the control of the transistor being the output of the comparator. The comparator's inputs are the current voltage level of the regulator's output and the specific ‘‘output’’ voltage which comes from some kind of voltage reference. The voltage reference is usually a Zener diode that has a miniscule amount of current passing through it; the comparator does not need a lot of current to operate.

Adding the current and temperature ‘‘crowbar’’ sensors is implemented something like in Fig. 12-15. When either the current output or temperature exceeds the preset limits, the reference voltage is pulled to ground using an NPN transistor (remember that the voltage reference is very low current so this can be done safely). In some regulators, if the current or temperature parameters are exceeded, they ‘‘latch’’ the failing state until power is removed and the crowbar conditions are reset. The need for the current sense and shut down should be pretty obvious to you; if the current drawn exceeds the

maximum rating for the PNP transistor, it could be damaged. The temperature sensor may be a bit more unexpected but shouldn't be surprising when you consider what is happening in the regulator when it is transforming a high voltage into a lower one. The difference between the input voltage and the regulated voltage multiplied by the current being drawn by the circuit being regulated is the power dissipated by the regulator. For example, if you had a 12 volt voltage source and a 5 volt regulator providing 200 mA current, the power being dissipated by the regulator would be 1.4 watts. This level of power dissipation could damage the internal circuitry of the regulator or, at the very least, raise the temperature of the part so that it does not work as designed.

The most popular linear voltage regulators that provide the crowbar features are the 78xx and 78Lxx series. The 78xx (or the LM2940 series of regulators which have the same pinout and package) shown in Fig. 12-16 ("xx" standing for the voltage, so a 5 volt regulator is a "7805") can normally source up to 500 mA and up to 1 A with heat sinking. The heat sink is used to dissipate the power and keep the temperature within the regulator less than 125°C, which is the crowbar temperature. For lower current applications (up to 100 mA), the 78Lxx (Fig. 12-17) can be used. For either device, the input voltage should be at least 2 volts above the regulated output voltage. When wiring the regulator in circuit, you should include at least 10 μF of capacitance on the input and a 0.1 μF capacitor on the output.

While the Zener diode and linear power supplies presented so far in this chapter are useful and easy to work with, they do have two concerns that can make them problematic when they are being used in a battery-powered application. First off, they require a higher voltage than the regulated output; this can be an issue when you want to use very simple power like two AA cells

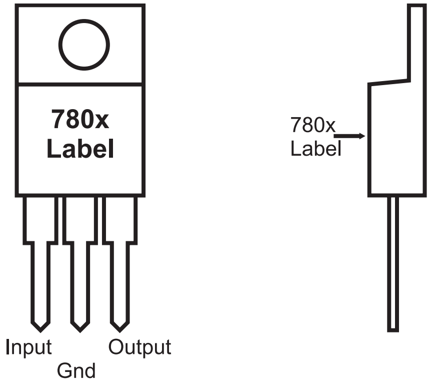

Fig. 12-16. 780x voltage regulator chip pinouts.

for a digital electronics circuit. Secondly, they are not terribly efficient. It isn't unusual for 80% or more of the power input to the Zener diode power supply to be lost and 40% or more lost in the linear power supply. What is required is a power supply circuit that is very efficient and will ''step up'' voltages.

While these two requirements seem impossible, they can actually be achieved very easily through the use of the ''switch mode power supply'' (SMPS). The basic SMPS circuit (Fig. 12-18) is quite simple and relies on the energy storing characteristic of the inductor or ''coil''. While the capacitor stores energy in the form of charge, the coil stores energy in the form of a magnetic field which is maintained by current running through the coil. When this current is shut off, the magnetic field produces a voltage ''spike'' (which I called ''kickback'' when discussing magnetic devices) that can be used as the basis for an output voltage.

Using the circled letters in Fig. 12-18, I have drawn the waveforms (Fig. 12-19) that you can expect to see in the SMPS. The ''Control'' signal is a PWM produced by a ''voltage controlled oscillator'' (VCO). A voltage controlled oscillator oscillates at a different frequency based on the voltage at an input. The input to the VCO used in the SMPS is the output voltage

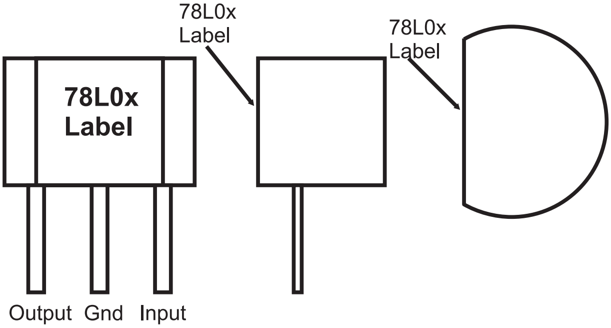

Fig. 12-17. 78L0x voltage regulator chip pinouts.

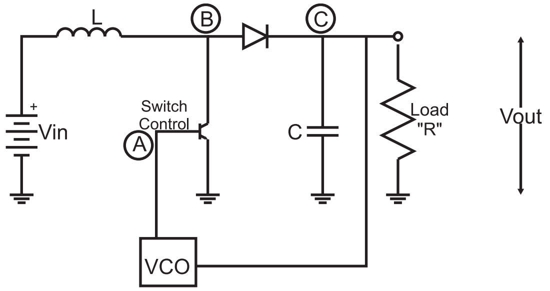

Fig. 12-18. Basic switch mode power supply (SMPS).

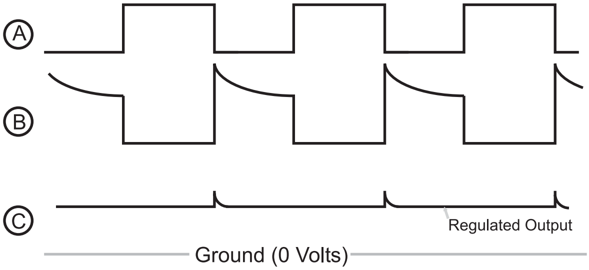

Fig. 12-19. Switch mode power supply operating waveforms.

of the power supply; the VCO frequency will change according to the power supply output to ensure the output stays as stable as possible at the required voltage. The output of the VCO is the base of a transistor that periodically pulls one side of the coil to ground, allowing current to flow through it. When the transistor connected to the coil is turned off, current flow through the coil stops and the magnetic field ‘‘kicks back’’, producing a higher voltage.

The operation of the VCO PWM output along with the coil’s response and the output voltage is shown in Fig. 12-19. When the VCO is turning on the transistor, the coil (symbol ‘‘L’’) is tied to ground and current flows through it. When the transistor is off, the coil kickback can be seen and any voltage greater than the current voltage output from the supply passes through the diode and is stored in the output capacitor. As I said above, if the output voltage is more or less than the target voltage, the VCO frequency changes along with the transistor control PWM, bringing the output voltage into line.

To determine the correct coil value as well as the PWM parameters, the following three formulas are used once the output voltage (‘‘V_{out}’’) is known along with the expected output current draw (‘‘I_{out}’’) and the input voltage (‘‘V_{in}’’). These formulas are used repeatedly until the values for ‘‘L’’ (the coil value), ‘‘T_{on}’’ (time the transistor is on) and ‘‘T_{off}’’ (time the transistor is off) are values that can be produced by reasonable hardware.

$$\begin{aligned} I_{peak} &= 2 \times I_{out} \times (V_{out}/V_{in}) \\ T_{off} &= L \times I_{peak}/(V_{out} - V_{in}) \\ T_{on} &= (V_{out}/V_{in}) - 1 \end{aligned}$$

Designing an SMPS is not a trivial exercise. While you may think you can do it using something like a 555 timer, I’m going to recommend that you use a commercially available chip that provides the function for you, like the LT1173-5. This chip can be used to create 5 volts (neccesary TTL and

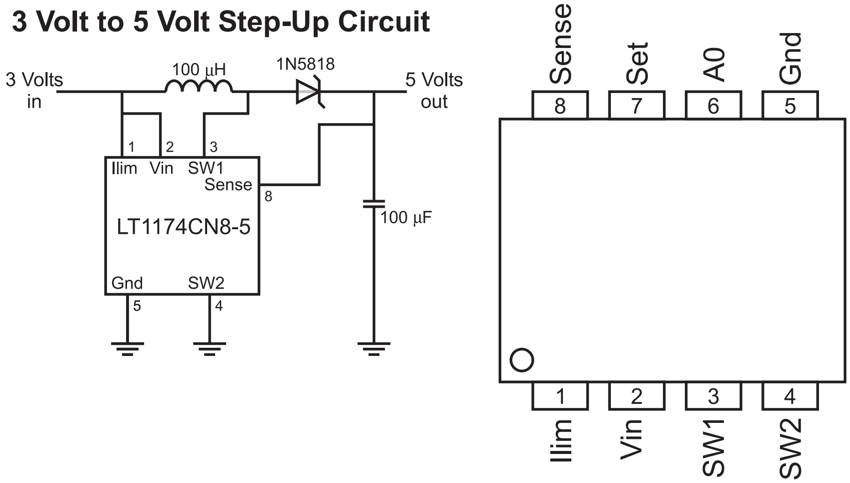

Fig. 12-20. LT1174CN8-5 switch mode power supply controller chip pinout and sample circuit.

many CMOS logic chips) from 3 volts, as shown in the basic circuit in Fig. 12-20.

With the appropriate regulator selected, you now have to find a source of DC current to power the application and regulator. By far the most popular way of providing power to an electronic device is by simply plugging it into a wall socket.

> I must caution you that the power coming out of your wall socket can conceivably destroy your application, cause a fire or hurt you (e.g. burns or electrocution). Despite the fact that it is commonly used for appliances, light and electronic devices in the home, electricity is not to be trifled with.
>
> The circuits provided below may not be appropriate for where you live. The information provided here is strictly ‘‘rule of thumb’’ and is primarily written for use in North America. If you are going to design a power supply for a specific country’s use, make sure you understand what are the characteristics of the local power supply, along with any laws or regulations that are appropriate when connecting to it.

Power coming from your wall sockets (‘‘the mains’’), comes in as either a 110 or 220 volts ‘‘peak-to-peak’’ as a ‘‘sine wave’’ with a frequency of 50 or 60 cycles per second (or ‘‘hertz’’ (‘‘Hz’’)). In North America, power is provided at 110–120 volts peak-to-peak voltage (typically 115 volts) at 60 Hz. Different countries around the world will use different peak-to-peak voltage levels and operating frequencies.

This power coming in is normally provided by a ‘‘socket’’, which is built into your walls. Figure 12-21 shows the layout of the socket and labels the individual connections. “Live” or “Hot” is the incoming alternating voltage sine wave shown in Fig. 12-21. “Neutral” is the return path for this current, while “Ground” is a shunt to “earth ground” if the circuit is damaged and the live voltage is passed to the neutral connection. If these three signals are being wired manually by convention, “Live” is black, “Neutral” is white and “Ground” is Green.

Because the AC voltage coming from the “mains” is so high and has positive and negative voltage components, it has to be converted into a lower DC voltage for the electronics. This is done in three stages. The first is reducing the voltage from more than 100 volts to 15 volts or less using a “transformer”. A transformer (Fig. 12-22) is a device made up of two coils that share their magnetic field. When current is passed through one coil, the second coil will produce an “inducted” voltage and current, which can be used to power the circuit. Figure 12-22 also gives the relationship between the voltage and current on the secondary side coil based on the number of turns for each coil.

Note that the current is inversely proportional to the turns ratio. In North America (which has 110 volts AC), an 8:1 transformer is often used. This means that with 110 volts in, there will be 14 volts out. For 220 volts, a 16:1 transformer should be used for the same voltage output.

While the voltage has been lowered, it is still “AC” and it is still going positive and negative. This voltage has to be “rectified” into a straight

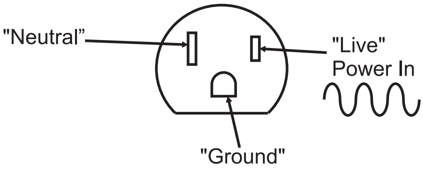

Fig. 12-21. North American wall plug.

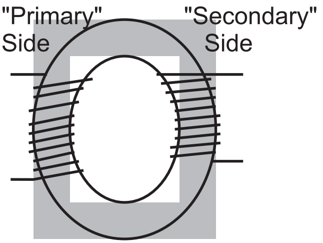

Electrical Characteristics:

$$\frac{\#\ \text{Turns Primary}}{\#\ \text{Turns Secondary}} = \frac{\text{Voltage Primary}}{\text{Voltage Secondary}} = \frac{\text{Secondary Current}}{\text{Primary Current}}$$

Fig. 12-22. AC voltage transformer operation.

DC voltage. This is done using diodes in either a "half wave" or "full wave" rectifier. Full wave rectifiers transform the positive and negative "lobes" of the AC circuit into a positive voltage, whereas the half wave rectifier "clips" the negative wave (providing half the total power available to the circuit). Inputting the rectified signal directly from the diodes into a voltage regulator should not be attempted; instead, a filtering electrolytic capacitor or a few tens of μF should be used. The filtered signal output from the full wave rectifier was shown in Chapter 3.

As long as the rectified signal does not drop below the minimum voltage of the Voltage Regulator, the regulated DC voltage output will be constant. The filtering cap should be a minimum of 10 μF with a good rule of thumb being that for digital circuits; a 20 μF capacitor is required for each Amp of current drawn. For DC electric motors, this value increases to 100 μF per amp drawn to help prevent inductive "kickback" "spikes" from being driven back through the transformer to the mains circuit.

Using the transformer, full wave rectifier, an electrolytic filter capacitor and a 7805 voltage regulator, a +5 volt 0.5 amp power supply for digital logic applications could be created, as shown in Fig. 12-23. The *voltage regulator* converts the rectified transformer-reduced AC voltage into a voltage that can be used by the digital logic.

There are a few things to note in Fig. 12-23. The first is that the mains ground is connected to the case and not to the "digital ground". In any DC-powered circuit, the negative terminal of the full wave rectifier can be called "digital ground", but should be left "floating" relative to "earth ground", which is provided by the AC plug. In this case, "digital ground" is simply a common negative terminal for the circuit. I have put a "fuse" in the power line, which will cut out in high current draw situations (like short circuits).

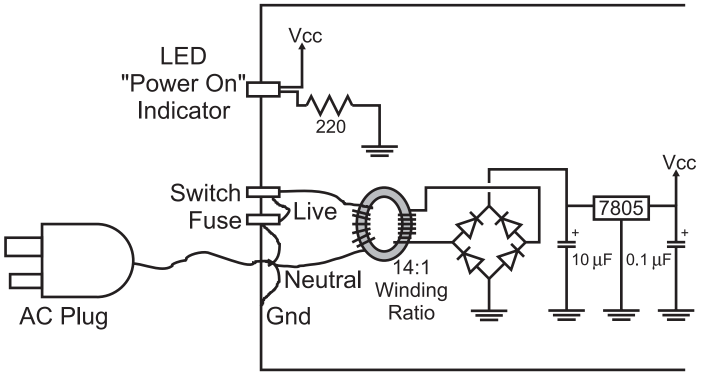

Fig. 12-23. Sample AC to 5 volt DC power supply for digital electronics.

It is rated at 0.1 amps, which may seem low, but remember that current output is inversely proportional to the turns ratio of the transformer: 0.1 amps at 110 volts translates into 1.4 amps at 8 volts at the output. Without this fuse, very large (and very dangerous) currents could build up inside the circuit. For example, 2 amps at 110 volts translates to 28 amps at 8 volts or 224 watts of power. Along with the fuse, the ‘‘Switch’’ in the circuit should be one that is certified for switching AC voltages. AC switches usually have a mechanical assembly inside them that ‘‘snaps’’ the switch contacts on and off. This minimizes ‘‘arcing’’ within the switch. This may seem hard to believe, but if you look inside an AC switch while it is opening or closing, you will see a blue spark and sometimes hear a ‘‘pop’’. This is caused by high inductive voltages produced by the transformer coils that ‘‘kickback’’ when the AC power is shut off.

If you do build mains power supply circuits, like this one, I recommend that you use 14-gauge stranded wire for all connections. Connections should consist of soldered connections (not household ‘‘Marette’’ connectors) for safety. ‘‘Heat shrink tubing’’ should be placed over all solder joints and bare wire. As well, only UL/CSA (or the local country testing organization) approved plugs, wires, switches, fuse holders and transformers should be used in a properly grounded metal case.

> If any of these terms are unfamiliar to you or you doubt your ability to build the circuit safely, then don’t build it!

Programmable Logic Devices

Programmable logic devices (‘‘PLDs’’) are chips which have logic gates and flip flops built in, but are not interconnected. The application designer will specify how the gates and flip flops are interconnected in order to create a portion of the application’s circuit. Most people feel that programmable logic devices are a relatively new invention, but they have been around for many years. It has only been quite recently (in the last 10 years or so) that reusable chip technology (i.e. EPROM and flash)-based PLDs have been available at prices hobbyists and small companies could afford.

There are several types of PLDs. The first is the simple array of logic gates and devices that are built of this type are known as ‘‘PALs’’ and ‘‘GALs’’ (I generically refer to them as ‘‘PALs’’). The chips themselves are quite simple and relatively easy to design circuits for. These circuits are normally arranged as a ‘‘sum of products’’ in which signals on the chip can be easily

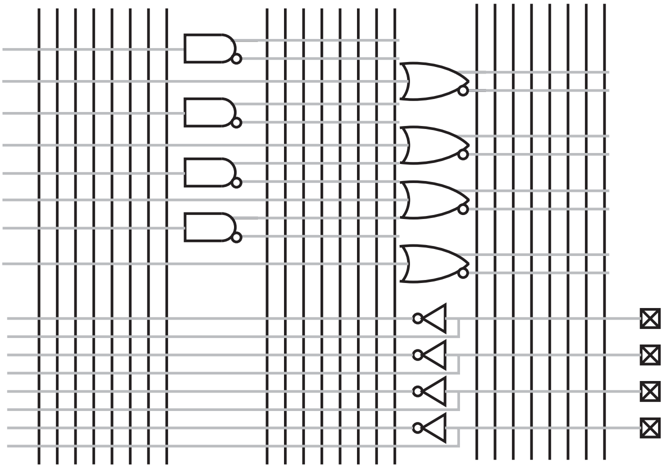

Fig. 12-24. Simple unprogrammed programmable logic device (PLD).

interconnected to form more complex logic functions. The chips are normally blocked out as a series of inputs and outputs, as shown in Fig. 12-24.

The vertical lines or "busses" in Fig. 12-24 are referenced to the gates and I/O pins they are connected to.

To form logic functions, the "sum of products" is used. In Fig. 12-24, a simple 4 I/O, 12 gate PAL is shown. Every output is driven on a bus in both positive as well as negative format. Connections are made between the gates and the busses to create logic functions.

For example, the "XOR" gate which is characterized by:

```
A XOR B = A ^ B
        = _A AND B OR A AND _B
        = (_A * B) + (A *_ B)
```

which is not often available in standard logic. Taking Fig. 12-24 and connecting the busses to the different I/O pins and gates within the PAL, I can implement the XOR gate, as shown in Fig. 12-25.

Note in Fig. 12-25, that an I/O pin changes from an input to an output by simply connecting it directly to a gate output. This feature allows the pins to be used as either input or output.

Options for PALs include varying numbers of inputs to the internal AND and OR gates. For the PLD shown in Fig. 12-25, I have left open the option that any of the pins can be used for any purpose. This is a bit unusual and, normally in PALs, the number of inputs to a gate is restricted. Another

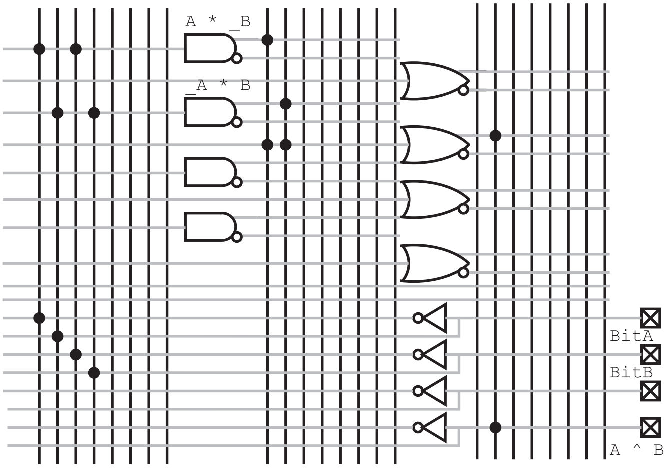

Fig. 12-25. PLD programmed as an XOR gate.

option is to include built in flip flops to store states and turn the PAL from a combinatorial circuit into a sequential one.

PALs may seem simple, but they can result in large decreases in the chip count for an application. In some cases, PALs may be more expensive than the chips they replace, but they reduce application power and board space chip requirements. These savings could result in all-over product savings. It is not unusual for 10 TTL chips to be replaced by a single PAL, resulting in huge PCB and power supply cost savings.

At the high end of the programmable logic device family range, some devices are virtually "ASICs" ("Application Specific Integrated Circuits") and use the same programming language ("VHDL") and development tools as ASICs. These complex parts generally have their functions broken up into "macros". An ASIC/PLD macro can be an AND, or XOR not, logic gate, flip flops or collections of functions (such as multiplexors and arithmetic logic units) which simplify the task of circuit development and eliminate the need for wiring individual gates into basic functions.

The high-end programmable logic device's programming information is often directly transferable to the technology. This allows initial production to use programmable logic devices that require little cost to program and, when the design is qualified, ASICs can be built at a chip foundry for reduced per unit costs.

Programmable logic devices have the advantage of being able to implement fast (less than 10 ns) logic switching, but they do not have the ability to store more than a few bits of data.

Often, programmable logic devices are used in proprietary circuits because their functions cannot be easily traced and decoded.

Programmable logic devices and ASIC development tools are generally function text based as opposed to graphically based applications (like a schematic drawing). This means that a text format, like the "XOR" definition above, must be used to define the functions. Most "compilers" for these statements are intelligent enough to pick the best gates within the device to work with and pick the best paths without your intervention. They are typically much more sophisticated (and expensive) than the compilers used for converting high-level program statements into instructions for a processor.

Quiz

1. The choices in processor design are:
   (a) Intel vs AMD vs PowerPC
   (b) CISC vs RISC, Princeton architecture vs Harvard architecture, hardcoded instruction execution vs state machine instruction execution
   (c) TTL vs CMOS logic
   (d) Speed vs minimal power consumption

2. Microcoded instructions are:
   (a) Short instructions which take less time to execute
   (b) Coded instructions that cannot be read by spies
   (c) Instructions that are specific to a microprocessor
   (d) State machine instructions outlining the steps needed to execute an instruction

3. Decimal 47.123 in binary is:
   (a) Invalid; you cannot perform this conversion
   (b) B'101111.00011111'
   (c) B'11111.101111'
   (d) 0x02F.1F7

4. Which statement is false? "Flash" memory cells:
   (a) Are designed from EPROM memory cells
   (b) Can be erased by applying an electrical voltage
   (c) Are built from flip flops
   (d) Are limited to 256 bits in size

5. DRAM Memory is:
   - (a) Faster than SRAM memory
   - (b) Less expensive per bit than SRAM memory
   - (c) More reliable than SRAM memory due to ‘‘refreshing’’
   - (d) More expensive per bit than SRAM memory
6. What is not a feature of the DC/DC power regulators presented in the book?
   - (a) They will convert AC to DC directly
   - (b) They have current limiting capability
   - (c) They have temperature limiting capability
   - (d) They have voltage ‘‘Brown out Reset’’ capability
7. With 12 volts coming in, the current limiting resistor for a 5 volt, 200 mA Zener diode:
   - (a) Insufficient information to calculate the resistor’s parameters
   - (b) 3.5 Ω, 10 watt
   - (c) 350 Ω, 1 watt
   - (d) 35 Ω, 2 watt
8. A switch mode regulator needs the following components to work:
   - (a) Capacitors, diodes and inductor
   - (b) Capacitor, diode and PWM driver
   - (c) Capacitors, diode, transistor, PWM driver and inductor
   - (d) Comparator, PWM driver, transistor and inductor
9. ‘‘PAL’’ is the acronym for:
   - (a) Pound and lever
   - (b) Peripheral aspect light
   - (c) Partial AND logic
   - (d) Programmable array logic
10. VHDL is used for:
    - (a) Defining PLD electrical parameters
    - (b) Defining PLD gate requirements
    - (c) Defining PLD gate operations
    - (d) Defining PLD speed parameters

CHAPTER 13

PC Interfacing Basics

From a practical point of view, chances are you will be designing an interface or enhancement to your PC. Most modern commercial devices utilize USB ports, but you can still do a lot of interesting projects with the ‘‘legacy’’ interfaces built into the PC. Along with this, a basic understanding of your PC will help you understand how commercial products are designed and may give you some ideas as to how you can design your own complex applications.

The PC ‘‘core’’ circuitry consists of the microprocessor, memory, the interrupt controller and a DMA controller, as shown in Fig. 13-1. This set of hardware can run any program or interface with hardware attached to this ‘‘local bus’’. While you may think of processor memory in terms of the megabytes that were advertised when you bought the PC, there are actually three different types of memory that are accessed.

The term ‘‘local memory’’ is kind of a loosely defined term that I use to describe memory on the PC’s motherboard and not on external cards or subsystems. There are a number of different kinds of memory used on the motherboard, each with a different set of characteristic features. The first type, ‘‘ROM’’ (‘‘Read Only Memory’’) is fairly slow and can only be read; it contains the PC start up (‘‘boot’’) code. Next, there is what I will call

Bus Clock
L2
DRAM
ROM

Fig. 13-2. PC memory access time comparison.

“main memory”, which is measured in tens or hundreds of megabytes (and was prominently advertised when you bought your PC) and is moderately fast.

The PC’s processor itself has “cache memory” which runs at the processor’s speed and, ideally, all execution takes place from this area as this will help speed up the operation of the PC. Figure 13-2 shows the number of clock cycles for the different cases of the PC’s processor reading from cache memory (at full local bus clock speed), main memory (which has 50 ns access time DRAMs) and ROM (150 ns access time). The importance of being able to run entire applications from cache memory should be obvious to you.

“DMA” stands for “Direct Memory Access” and consists of a hardware device that can be programmed to create addressing and control signals to move data between devices within the system without involving the processor. DMA is most typically used in the PC for moving data to and from the disk drives.

Interrupts are hardware events, passed to the “8237 interrupt controller” chip that requests the PC’s processor to stop what it is currently doing and respond to the external request. This request does not have to be responded to immediately and it is up to the programmer's discretion to decide how to respond to the request.

All PC systems have multiple busses for system expansion and improved communications. Before going too much further, I should list the characteristics of what a computer bus is. A computer bus is defined as having:

1. A method for the controlling microprocessor to provide addresses bus hardware for both memory and I/O access.
2. The ability of the cards to request interrupt and DMA processing by the controlling microprocessor.
3. The ability to enhance the operation of the PC.

In a modern PC, there are usually three primary busses, each one delineated by the access speed they are capable of running at and the devices normally attached to them (see Fig. 13-3). The three busses have evolved over time to provide data rates consistent for the needs of the different devices. You might consider that there is a problem with cause and effect, but the busses and devices attached to them have sorted themselves out over the years.

The "Front Side Bus" (usually referred to by its acronym "FSB") runs at a very high speed specific to the processor. This is used by the processor to access DRAM memory directly as well as provide an interface to the system peripherals.

The "PCI" ("Personal Computer Interface") Bus. This bus is not only a staple of all modern PCs but is also available on many other system architectures as well. This allows PCI bus cards to be used across a number of

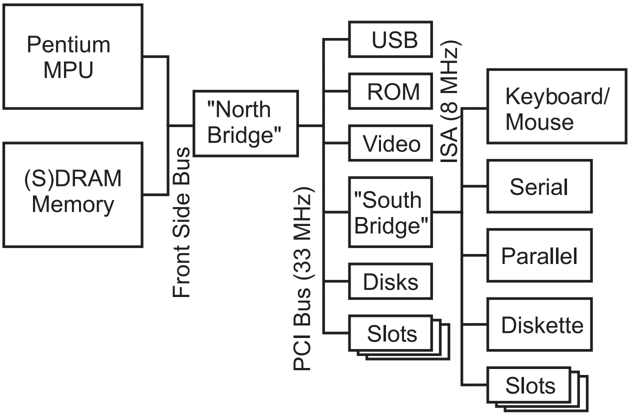

Fig. 13-3. Modern PC block diagram.

different systems and eliminates the need for designers and manufacturers to replicate their products for different platforms. PCI is somewhat of a "hybrid" bus, with some internal features of the PC (notably video and hard file controllers) using the PCI busses built into the copper traces on the motherboard as well as providing access to adapter cards in "slots". PCI is notoriously difficult to create expansion cards for. Along with the fairly high data rate speed (33 and 66 MHz), there are data transfer protocols which generally require an ASIC to decode and process bus requests.

The last bus interfaces the "legacy" interfaces of the PC together and is known as the "Industry Standard Architecture" ("ISA") bus. This bus typically has a data transfer speed of 125 ns – the same as the original PC/AT. When you are interfacing digital electronic devices to your PC, chances are the interface will be connected to this bus.

The Parallel (Printer) Port

When hardware is to be interfaced with the PC, often the first method chosen is the "Parallel" (Printer) port. If I was being introduced to the PC for the first time, I would probably look at this method first as well, but as I have learned more about the PC, using the parallel port would actually be one of the *last* methods that I would look at. The parallel port is really the most difficult interface in the PC to use because it is really device (printer) specific, has a limited number of I/O pins and is very difficult to time operations with accuracy. The only reason why I would see applications using a parallel port for interfacing is because, electronically, it does not need a level translator and can connect directly to TTL/CMOS logic.

In the 1970s, the Centronics Corporation developed a 25 pin "D-Shell" connector standard for wiring a computer to their printers. The early printer interfaces in the PC, after sending a byte, would wait for a handshaking line to indicate that the printer was ready for the next character before sending the next one. As you could imagine, this method was very slow and took up all the PC's cycles in printing a file.

This "pinout" very quickly became a standard in the computer industry. This connector consisted of an eight-pin data output port with strobe, four control lines passed to the printer and five status lines from the printer, as shown in Fig. 13-4. By the time the PC was being developed, this interface was the de facto industry standard and was chosen by IBM to help make the PC an "Industry" standard. When the printer port for the PC was being

developed, little thought was given to enhancing the port beyond the then current standard level of functionality.

To improve the functionality of the printer port, IBM, when designing the PC/AT, changed the eight data bit output only circuitry to allow data bits to be output as well as read back. This was accomplished by using pulled up open collector outputs that were passed from the ‘‘Data Latch’’ of Fig. 13-4, to the 25 pin D-Shell connector and on to the ‘‘Data Buffer’’, which could read the eight bits and see if anything was changed.

When a read of the eight data bits takes place, the eight output bits should all be ‘‘High’’ to allow the parallel port’s pull ups and the open collector outputs of the peripheral device to change the state of the pins. The bi-directional data capability in the PC/AT’s parallel port allowed hardware to interface to the PC to be very easily designed. Further enhancing the ease in which devices could be designed to work with the parallel port was the standard timing provided by the PC/AT’s ISA bus and BIOS.

Surprisingly, given this background, the biggest problem today with interfacing to the parallel port is timing signals properly. Depending on the different PCs that I have experimented with, I have seen parallel I/O port read and write timings from about 700 ns to less than 100 ns. When you design your interface to the IBM PC, you can either ignore the actual timings of the parallel port and execute signals that are many milliseconds long, ‘‘tune’’ the code to the specific PC you are working with or add a time delay function, like a 555 wired as a monostable that the PC can poll from the printer port to properly time its I/O operations.

There are three registers that you will have to access from your PC program to control the parallel port. The "Control Register", provides an operating control to the external device as well as to the internal interrupt function of the parallel port. The "Status Buffer" is read to poll the status bits from the printer. The last register, called "Data", allows eight bits to be written or read back from the parallel port. Starting at a parallel port (known as "LPT" in the PC), the registers are addressed as shown in Table 13-1 relative to a "Base" address which is at 0x0378 and 0x0278 for "LPT1" and "LPT2", respectively.

When the parallel port passes data to a printer, the I/O pins create the basic waveform shown in Fig. 13-5. It is important to note that the Printer BIOS routines will not send a new character to the printer until it is no longer "Busy". When "Busy" is no longer active, the "Ack" line is pulsed active, which can be used to request an interrupt to indicate to data output code that

the printer is ready to accept another character. The timing of the circuit for printer applications is quite simple, with 0.5 μs minimum delays needed between edges on the waveforms in Fig. 13-5.

Video Output

The first computer CRT display was the "vector" display in which the "X-Y" deflection plates moved the electron beam to a desired location on the screen and then drew a line to the next location. This was repeated until the entire image was drawn on the screen (at which time the process started over). This was popular in early computers because only a modest amount of processing power and video output hardware was needed to draw simple graphics. Because of the way the vector displays operated, a complex image was often darker than and could "flash" more than a "raster" (TV-like) display because a simple image would require fewer vector "strokes" and could be refreshed more often. Vector displays enjoyed some popularity in early computer video displays (including video games), but really haven't been used at all for over 10 years.

Today, a more popular method of outputting data from a computer is to use a "raster" display, in which an electron beam is drawn across the cathode ray tube in a regular, left to right, up and down, pattern. When some detail of the image is to be drawn on the screen, the intensity of the beam is increased when the beam passes a particular location on the screen, which causes the phosphors to glow more brightly, as shown in Fig. 13-6. If you have an old

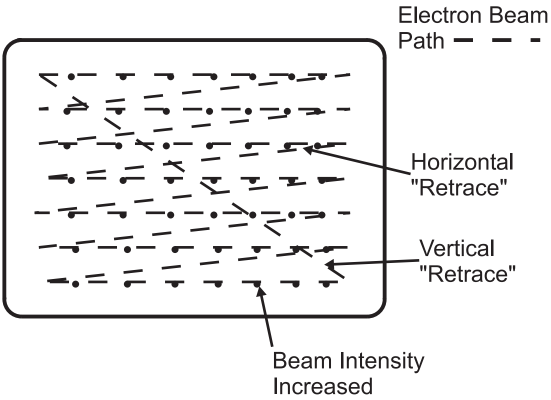

Fig. 13-6. Video raster.

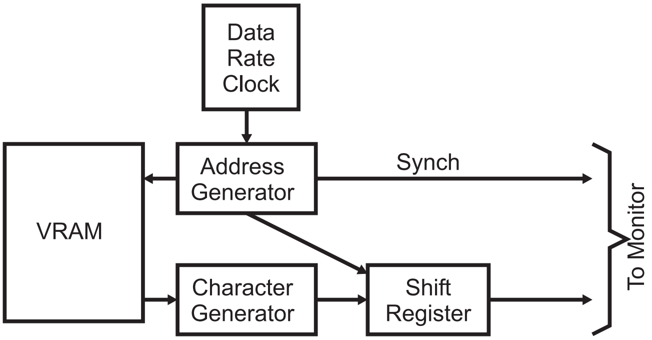

Fig. 13-7. Basic computer video driver circuit.

black and white TV (or monochrome computer monitor), chances are you can increase the “brightness”/“contrast” controls on a dark signal to see the different features I’ve shown above.

All raster computer output hardware consists of a shift register fed by data from a “Video RAM” (“VRAM”). In Fig. 13-7, the data to be output is read from the VRAM and then passed to a character generator, which converts the data from the Video RAM into a series of dots appropriate for the character. This series of dots is then shifted out to the hardware that drives the raster on the video monitor. If graphical data is output, then the “Character Generator” is not needed in the circuit and the output from the VRAM is passed directly to the shift register. The shift register may also be connected to a “DAC” (“Digital Analog Converter”), which converts the digital data into a series of analog voltages that display different intensities of color on the display.

The addresses for each byte’s data to be transferred to the display are accomplished by using an “Address Generator”, which controls the operation of the display (Fig. 13-8). The Address Generator divides the “data rate” (the number of “pixels” displayed per second on the screen) into character-sized “chunks” for shifting out, resets address counters when the end of the line is encountered and also outputs “Synch” information for the monitor to properly display data on the screen.

The circuit in Fig. 13-8 shows an example address generator for an 80 character by 25-row display. This circuit resets the counters when the end of the line and “field” (end of the display) is reached. At the start of the line and “field”, horizontal and vertical synch information is sent to the monitor so the new field will line up with the previous one.

I have presented this information on standard video inputs to give you some background on how “NTSC” televisions work and what their input

signals look like. "NTSC" is the television "composite video" standard for North America and is an acronym for the "National Television Standards Council", the governing body put in place for television in the United States in the 1940s (today, television broadcasting technical standards are controlled by the Federal Communications Commission or FCC).

"Composite NTSC" is the signal typically received by your TV set and consists of both the data input streams along with the formatting information (called synchronization or synch pulses) that are used by the TV set to recognize where the incoming signal is to be placed on the screen. The incoming data, shown in Fig. 13-9 consists of voltage levels (from 0 to 0.6 volts) varying over time. This data is wiped across the CRT from left to right as a single line raster.

On the left-hand side of the incoming serial data shown in Fig. 13-9, I have drawn the data as a typical, analog video stream. The analog voltage levels are used to control the output level of the electron ‘‘gun’’ in the CRT: the higher the input voltage level, the brighter the output on the current raster of the CRT display, as shown at the bottom of the diagram. To the right of the analog data of Fig. 13-9, I have drawn some signals that jump from 0 volts to 0.6 volts and back again. This section of the raster is labeled as ‘‘Digital Data’’. I call this digital data because it is either all on or all off and it can be read as data by simply comparing whether the data is above or below the ‘‘threshold’’ marked on Fig. 13-9.

The start of each new line is specified by the inclusion of a ‘‘horizontal synch pulse’’ (‘‘hsynch’’), as shown in Fig. 13-10. This pulse is differentiated from the serial data by being at a voltage level less than the ‘‘black’’ level – this is where the term ‘‘blacker than black’’ comes from. Before and after the synch pulse, there are two slightly negative voltage regions called the ‘‘front porch’’ and ‘‘back porch’’, respectively. The front porch is 1.4 µs long, the back porch and horizontal synch pulse are 4.4 µs each. The entire line is 63.5 µs in length, and when you take away the 10.2 µs of horizontal synch information, you are left with 53.3 µs per line for the analog or digital data.

There are 262 or 263 lines of data sent to the TV, with the first 12 normally being at the −0.08 volt ‘‘porch’’ level and called the ‘‘vertical blanking interval’’. I say it is normally at the −0.08 volt porch level, except when ‘‘closed captioning’’ information is available. Closed captioning, as I’m sure you are aware, is the text that comes on the screen to allow hearing impaired

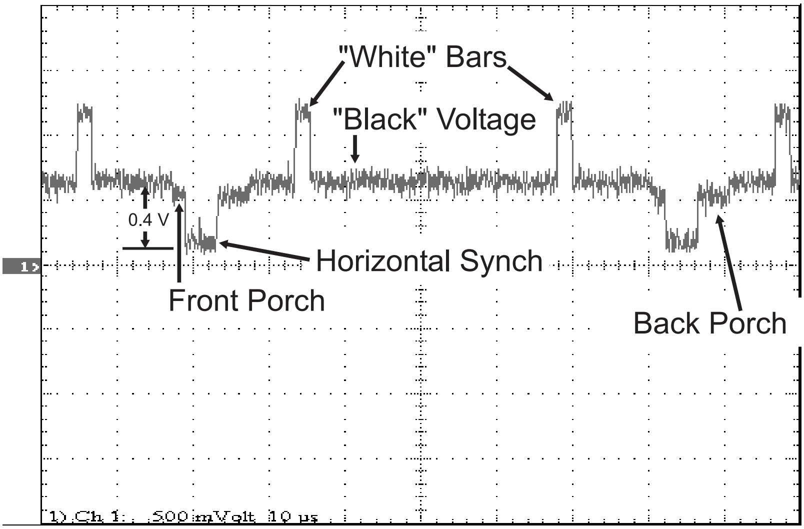

Fig. 13-10. Full NTSC composite video line.

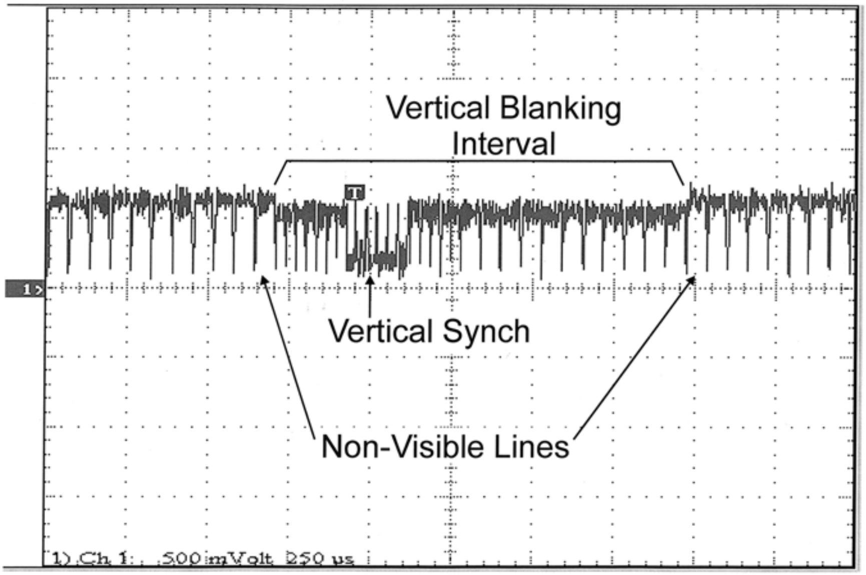

Fig. 13-11. Composite NTSC video vertical synch.

people to watch TV. When closed captioning data is included in the vertical blanking interval, digital pulses, similar to the ones shown in Fig. 13-11 are built into each line and decoded by circuitry built into the TV.

The TV set does not have a counter built into it to indicate when the CRT's gun should reset and go back to the top of the screen. Instead the incoming signal indicates when a vertical retrace must take place by its inclusion of a ‘‘vertical synchronization pulse’’ (‘‘vsynch’’). The oscilloscope picture (Fig. 13-11) shows what the vertical synch pulse looks like: it is actually a series of half-sized lines followed by a number of inverted half-sized lines.

So far, I have described NTSC video as having 262 or 263 lines, but if you look at the specifications for a TV set, you will see that it can accept 525 lines of NTSC data. A full NTSC screen consists of two ‘‘fields’’ of data: one 262 lines in size and the other 263 lines. The fields are offset by one half the width of a line – after the first field is displayed, the second fills in the spaces between the lines displayed by the first field. This is called ‘‘interlacing’’ the two fields together into a single ‘‘frame’’.

With the information contained within this section, you have enough information to create a monochrome video output circuit. I've done it a number of times with basic microcontrollers; as long as you keep your field width, vertical and horizontal synch pulses timed consistently, you will find that you can build your own composite video output display that you can send to an old TV. Even though with the information contained here, you should be able to design an NTSC composite video output perfectly, I still don't recommend trying it out on the family's good TV.

Synchronous Serial Interfaces (SPI, I2C, Microwire)

There are two very common synchronous data protocols, Microwire and SPI, from which a variety of standard devices (memory and peripheral functions) have been designed around, including serial EEPROMs, sensors and other I/O functions. I consider these protocols to be methods of transferring synchronous serial data rather than intelligent network protocols because each device is individually addressed (even though the clock/data lines can be common between multiple devices). If the chip select for the device is not asserted, the device ignores the clock and data lines. With these protocols, only a single "Master" can be on the bus. Normally, just eight bits of data are sent out at a time. For protocols like Microwire where a "Start bit" is initially sent, the "Start bit" is sent using direct reads and writes to the I/O pins. To receive data, a similar circuit would be used, but data would be shifted into the shift register and then read by the microcontroller.

The Microwire protocol is capable of transferring data at up to one megabit per second. Sixteen bits are only transferred at a time. After selecting a chip and sending a start bit, the clock strobes out an eight bit command byte, followed by (optionally) a 16 bit address word transmitted and then another 16 bit word either written or read by the microcontroller.

With a one megabit per second maximum speed, the clock is both high and low for 500 ns. Transmitted bits should be sent 100 ns before the rising edge of the clock. When reading a bit, it should be checked 100 ns before the falling edge of the clock. While these timings will work for most devices, you should make sure you understand the requirements of the device being interfaced to.

The SPI protocol is similar to Microwire, but with a few differences:

1. SPI is capable of up to 3 megabits per second data transfer rate.
2. The SPI data "word" size is eight bits.
3. SPI has a "Hold" which allows the transmitter to suspend data transfer.

4. Data in SPI can be transferred as multiple bytes known as ‘‘Blocks’’ or ‘‘Pages’’.

Like Microwire, SPI first sends a byte instruction to the receiving device. After the byte is sent, a 16 bit address is optionally sent followed by eight bits of I/O. As noted above, SPI does allow for multiple byte transfers. An SPI data transfer is shown in Fig. 13-12. The SPI clock is symmetrical (an equal low and high time). Output data should be available at least 30 ns before the clock line goes high and read 30 ns before the falling edge of the clock.

When wiring up a Microwire or SPI device, one trick that you can do to simplify the microcontroller connection is to combine the ‘‘DI’’ and ‘‘DO’’ lines into one pin, as was shown earlier in the book.

The most popular form of microcontroller network is ‘‘I2C’’, which stands for ‘‘Inter-Intercomputer Communications’’. This standard was originally developed by Philips in the late 1970s as a method to provide an interface between microprocessors and peripheral devices without wiring full address, data and control busses between devices. I2C also allows sharing of network resources between processors (which is known as ‘‘Multi-Mastering’’). Your PC probably has several I2C busses built into it for controlling system control and monitoring functions.

The I2C bus consists of two lines: a clock line (‘‘SCL’’) which is used to strobe data (from the ‘‘SDA’’ line) from or to the master that currently has control over the bus. Both these bus lines are pulled up (to allow multiple devices to drive them). A I2C controlled stereo system might be wired as shown in Fig. 13-13.

The two bus lines are used to indicate that a data transmission is about to begin as well as pass the data on the bus. To begin a data transfer, a ‘‘Master’’ puts a ‘‘Start Condition’’ on the bus. Normally, when the bus is in

the "Idle State", both the clock and data lines are not being driven (and are pulled high). To initiate a data transfer, the master requesting the bus pulls down the SDA bus line followed by the SCL bus line. During data transmission this is an invalid condition (because the data line is changing while the clock line is active/high). Each bit is then transmitted to or from the "Slave" (the device the message is being communicated with by the "Master") with the negative clock edge being used to latch in the data. To end data transmission, the reverse is executed; the clock line is allowed to go high, which is followed by the data line.

Data is transmitted in a synchronous (clocked) fashion. The most significant bit is sent first and after eight bits are sent, the master allows the data line to float (it doesn't drive it low) while strobing the clock to allow the receiving device to pull the data line low as an acknowledgment that the data was received. After the acknowledge bit, both the clock and data lines are pulled low in preparation for the next byte to be transmitted or a Stop/Start Condition is put on the bus. Fig. 13-14 shows the data waveform.

Sometimes, the acknowledge bit will be allowed to float high, even though the data transfer has been completed successfully. This is done to indicate that the data transfer has completed and the receiver (which is usually a "slave device" or a "Master" which is unable to initiate data transfer) can prepare for the next data request.

There are two maximum speeds for I2C (because the clock is produced by a master, there really is no minimum speed). "Standard Mode" runs at up to 100 kbps and "Fast Mode" can transfer data at up to 400 kbps.

Asynchronous Serial Interfaces

Understanding how asynchronous serial communications works is easy; implementing them on a PC is frustrating and hard and used to be especially true for casual PC owners. This situation is improving with newer high-speed interface connection protocols (USB and Firewire), but actually sitting down and getting RS-232 communication between two devices working can be a pain. Much of the information I will present on RS-232 in this section will seem quite obvious, but I urge you to read through this material as there are some tricks and information contained here that could probably get you out of a bind or two.

Asynchronous long distance communications came about as a result of the Baudot "teletype". This device mechanically (and, later, electronically) sent a string of electrical signals (which we would call "bits"), like the one shown in Fig. 13-15, to a receiving printer. This data packet format is still used today for the electrical asynchronous transmission protocols described in the following sections. With the invention of the teletype, data could be sent and retrieved automatically without having an operator having to sit by the teletype all night unless an urgent message was expected.

The Baud Rate specified for the data transmission is the maximum number of possible data bit transitions per second (measured in "bits per second", abbreviated to "bps"). This includes the "Start", "Parity" and "Stop" bits at the ends of the data "packet" shown in Fig. 13-15 as well as the five data bits

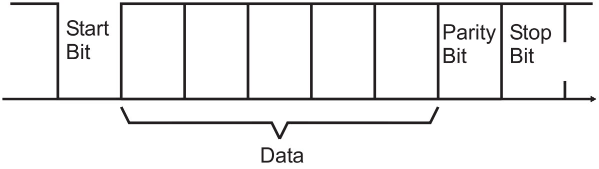

Fig. 13-15. Five-bit Baudot data packet.

in the middle. I use the term "packet" because we are including more than just data (there is also some additional information in there as well), so "character" or "byte" (if there were eight bits of data) are not appropriate terms. This means that for every five data bits transmitted, eight bits in total are transmitted (which means that nearly 40% of the data transmission bandwidth is lost in teletype asynchronous serial communications).

The "Data Rate" is the number of data bits that are transmitted per second. For this example, if you were transmitting at 110 baud, the actual data rate is 68.75 bits per second (or, assuming five bits per character, 13.75 characters per second).

With only five data bits, the Baudot code could only transmit up to 32 distinct characters. To handle a complete character set, a specific five-digit code was used to notify the receiving teletype that the next five-bit character would be an extended character. With the alphabet and most common punctuation characters in the "primary" 32, this second data packet wasn't required very often. In the data packet shown in Fig. 13-15, there are three control bits. The "Start Bit" is used to synchronize the receiver to the incoming data. In most hardware circuits designed to read an asynchronous serial packet, there is an overspeed clock running at 16 times the incoming bit speed which samples the incoming data and verifies whether or not the data is valid. When waiting for a character, the receiver hardware polls the line repeatedly at 1/16 bit period intervals until a "0" ("Space") is detected (down arrow at the left of Fig. 13-16). The receiver then waits half a cycle before

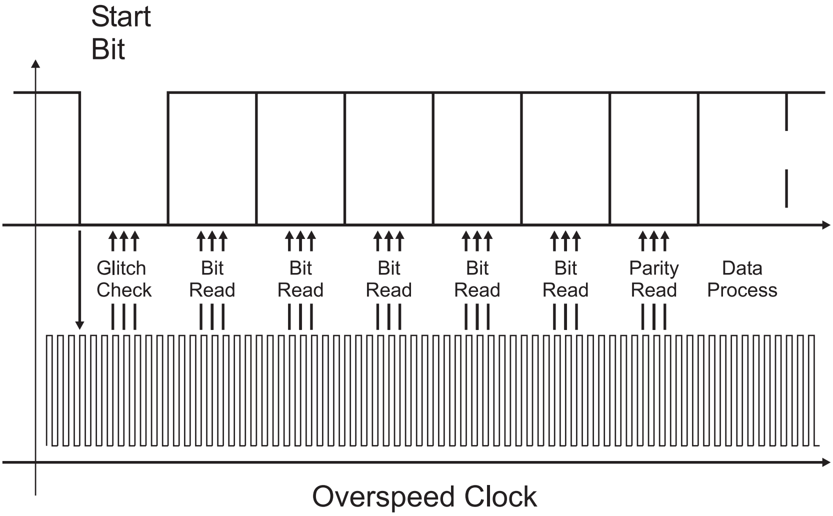

Fig. 13-16. Asynchronous serial data read.

polling the line again to see if a ‘‘glitch’’ was detected and not a Start bit. This polling takes place in the middle of each bit to avoid problems with bit transitions (or if the transmitter’s clock is slightly different from the receivers, the chance of misreading a bit will be minimized).

Once the Start bit is validated, the receiver hardware polls the incoming data once every bit period multiple times (again to ensure that glitches are not read as incorrect data).

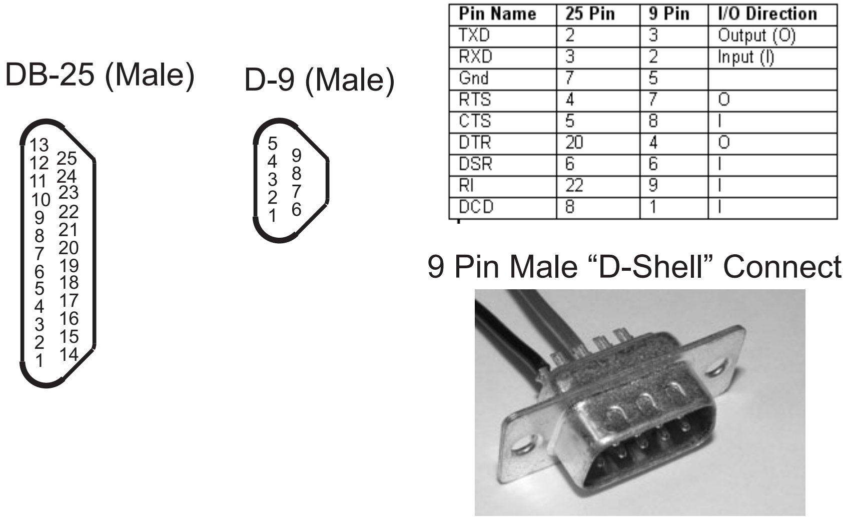
The ‘‘Stop’’ bit was originally provided to give both the receiver and the transmitter some time before the next packet is transferred (in early computers, the serial data stream was created and processed by the computers and not custom hardware, as in modern computers).

The ‘‘Parity’’ bit is a crude method of error detection that was first brought in with teletypes. The purpose of the parity bit is to indicate whether the data was received correctly. An ‘‘odd’’ parity meant that if all the data bits and parity bits set to a ‘‘Mark’’ were counted, then the result would be an odd number. ‘‘Even’’ parity is checking all the data and parity bits and seeing if the number of ‘‘Mark’’ bits is an odd number. Along with even and odd parity, there are ‘‘Mark’’, ‘‘Space’’ and ‘‘No’’ parity. ‘‘Mark’’ parity means that the parity bit is always set to a ‘‘1’’, ‘‘Space’’ parity is always having a ‘‘0’’ for the parity bit and ‘‘No’’ parity is eliminating the parity bit all together. I said that parity bits are a ‘‘crude’’ form of error detection because they can only detect one bit error (i.e. if two bits are in error, the parity check will not detect the problem). If you are working in a high induced noise environment, you may want to consider using a data protocol that can detect (and, ideally, correct) multiple bit errors.

The most common form of asynchronous serial data packet is ‘‘8-N-1’’, which means eight data bits, no parity and one stop bit. This reflects the capabilities of modern computers to handle the maximum amount of data with the minimum amount of overhead and with a very high degree of confidence that the data will be correct.

Having reviewed the data protocol for asynchronous serial communications, let’s go on and look at the electrical specifications, starting with the connectors that you will find on the back of your PC (Fig. 13-17). Either a male 25 pin or male 9 pin connector is available on the back of the PC for each serial port – chances are you will have a 9 pin connector because it takes up the least amount of space.

Working with MS-DOS in early systems, only a maximum of four serial ports could be addressed by the PC, and of these probably only two were useable for connecting external devices to the PC due to conflicts with other hardware devices. In modern systems, which have ‘‘Plug and Play’’ capabilities and the Windows operating system, which can allocate resources



Pin Name	25 Pin	9 Pin	I/O Direction
TXD	2	3	Output (O)
RXD	3	2	Input (I)
Gnd	7	5	
RTS	4	7	O

DTR	20	4	O
DSR	6	6	I
RI	22	9	I
DCD	8	1	I

Fig. 13-17. PC asynchronous serial port connectors and pinouts.

throughout the system, the number of standard serial ports has been greatly expanded. My personal record is 64 serial devices for environmental chamber status test software.

The standard RS-232 data rates available to you in the PC are listed in Table 13-2. As an interesting exercise, I suggest that you find the reciprocal of the data rates listed in Table 13-2, multiply by 1,000,000 and then divide by 13 – what you will find is that the results for the data rates starting at 1200 bps and going higher will have a very small fraction. In fact, the error will be much less than 0.1%! This is a good trick to keep in your hip pocket when you have to implement an RS-232 interface and you don't have any crystals that have been cut specifically to provide a multiple of these data rates.

Asynchronous communications based on the Baudot teletype/RS-232 is known as "Non-Return to Zero" ("NRZ") asynchronous communications, because at the end of each data packet the serial line is high. There are other methods of sending asynchronous serial data, with one of the most popular being "Manchester encoding". In this type of data transfer, each bit is synchronized to a "start" bit and the following "Data Bits" are read with the "space" dependent on the value of the bit.

Manchester encoding is unique in that the "Start Bit" of a packet is quantitatively different from a "1" or a "0" (shown in Fig. 13-18). This allows a receiver to determine whether or not the data packet being received is actually at the start of the packet or somewhere in the middle (and should be ignored until a start bit is encountered).

Table 13-2 Standard RS-232 data rates.

Data rate
110 bps
150 bps
300 bps
600 bps
1200 bps
2400 bps
4800 bps
9600 bps
19200 bps
38400 bps
57600 bps
115200 bps

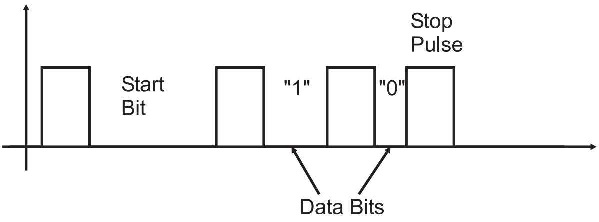

Fig. 13-18. Manchester data encoding.

Manchester encoding is well suited for situations where data can be easily interrupted or there is a conflict in the middle of data reception. Because of this, it is the primary method of data transmission for infrared control (such as used in your TV's remote control).

RS-232 Electrical Standards

In the previous section, I didn't tell the whole story about RS-232 asynchronous serial communications. I left out one very important point – signals do not travel at the same voltage levels as what we've discussed so far in the book. When RS-232 was first developed into a standard, computers and the electronics that drive them were still very primitive and unreliable. Because of that, we've got a couple of legacies to deal with and this can complicate connecting digital electronics circuits to another device using RS-232.

The biggest concern is the voltage levels of the data. A "Mark" ("1") is specified to be -3 volts to -12 volts and a "Space" ("0") is $+3$ volts to $+12$ volts. This means that there must be some kind of voltage level conversion when passing RS-232 to or from digital electronic devices. There are a number of ways of doing this.

Before working with the voltage levels, I just want to say a few words about the "handshaking" signals built into RS-232 (these are all the RS-232 connections other than RX, TX and GND in Fig. 13-17). These six additional lines (which are at the same logic levels as the transmit/receive lines) are used to interface between devices and control the flow of information between computers.

The "Request To Send" ("RTS") and "Clear To Send" ("CTS") lines are used to control data flow between the computer ("DCE") and the modem ("DTE" device). The "Data Transmitter Ready" ("DTR") and "Data Set Ready" ("DSR") lines are used to establish communications. There are two more handshaking lines that are available in the RS-232 standard that you should be aware of, even though chances are you will never connect anything to them. The first is the "Data Carrier Detect" ("DCD"), which is asserted when the modem has connected with another device (i.e. the other device has "picked up the phone"). The "Ring Indicator" ("RI") is used to indicate to a PC whether or not the phone on the other end of the line is ringing or if it is busy. Few of these lines are used in modern RS-232 applications and, as shown in Fig. 13-19, the DTR/DSR and CTS/RTS pairs are often simply shorted together to avoid any "hardware handshaking" issues with the PC.

There is a common ground connection between the DCE and DTE devices. This connection is critical for the RS-232 level converters to determine the actual incoming voltages. The ground pin should never be connected to a chassis or shield ground (to avoid large current flows or be shifted and prevent accurate reading of incoming voltage signals). Incorrect grounding of an application can result in the computer or the device it is

interfacing having to reset or have they power supplies blow a fuse or burn out. The latter consequences are unlikely, but I have seen it happen in a few cases. To avoid these problems make sure that chassis and signal grounds are separate or connected by a high value (hundreds of k Ω) resistor.

The most popular method for converting TTL/CMOS Logic signals to RS-232 levels is to use the MAXIM MAX232 (see Fig. 13-20,) which has a built in charge-pump voltage generator. This chip is ideal for implementing three-wire RS-232 interfaces (or to add a simple DTR/DSR or RTS/CTS handshaking interface). Ground for the incoming signal is normally connected to the digital electronics ground. Along with the MAX232, MAXIM and some other chip vendors have a number of other RS-232 charge-pump equipped devices that will allow you to handle more RS-232 lines (to include the handshaking lines). Some charge-pump devices that are also available do not require the external capacitors that the MAX232 chip does, which will simplify the layout of your circuit (although these chips do cost quite a bit more).

The next method of translating RS-232 and TTL/CMOS voltage levels is to use the transmitter's negative voltage as the circuit, as Fig. 13-21 shows. This circuit relies off of the RS-232 communications, only running in ''Half-Duplex'' mode (i.e. only one device can transmit at a given time). When the external device wants to transmit to the PC, it sends the data either as a ''Mark'' (leaving the voltage being returned to the PC as a negative value) or as a ''Space'' by turning on the transistor and enabling the positive voltage output to the PC's receivers. If you go back to the RS-232 voltage specification drawing, you'll see that +5 volts is within the valid voltage range for RS-232 ''Spaces''. This method works very well (consuming just about no power) and is obviously a very cheap way to implement a three-wire RS-232 bi-directional interface. There is a chip, the Dallas Semiconductor DS275, which incorporates the circuit above (with a built-in inverter) into the single package shown, making the RS-232 very simple.

Before finishing, I want to make a final point on three wire RS-232 connections. The first is that it cannot be implemented blindly; in about 20% of the RS-232 applications that I have had to do over the years, I have had to implement some subset of the total seven wire (transmit, receive, ground and four handshaking lines) protocol lines. Interestingly enough, I have never had to implement the full hardware protocol. This still means that four out of five times if you wire the connection as shown in Fig. 13-19, the application would have worked.

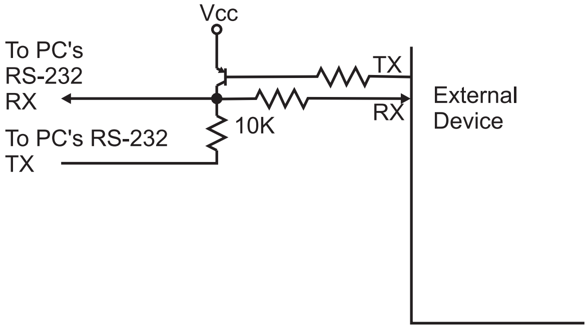

Fig. 13-21. ''Voltage stealing'' RS-232 interface.

Quiz

1. Which type of memory responds in the least amount of time?
   (a) Processor cache
   (b) All three types respond equally fast
   (c) Main Memory (S)DRAM
   (d) Processor ROM

2. What is not a characteristic of a computer bus?
   (a) Controlled by a central processor
   (b) The ability of peripherals on the bus to request information
   (c) Data can be read/written to peripheral busses
   (d) Keeping a log of the processor bus accesses

3. The minimum timing between signal edges in the parallel port is:
   (a) 0.5 µs
   (b) 0.5 ms
   (c) 0.5 ns
   (d) There are no delays; the port works completely asynchronously

4. The raster display on a video display looks like:
   (a) A series of parallel lines going across the display
   (b) Parallel lines that loop back like plough lines in a farmer's field
   (c) A series of small dots drawn on the video display
   (d) A series of brush strokes on the video display

5. "Horizontal synch" in a video display:
   (a) Moves the electron beam in the CRT to the left
   (b) Moves the electron beam in the CRT to the top
   (c) Starts the raster going side to side
   (d) Is needed for CRTs laid down on their side

6. Devices on a synchronous serial bus are normally referred to as:
   (a) "Dominant" and "Recessive"
   (b) "Master" or "Slave"
   (c) "1" or "0"
   (d) "Transmitter" or "Receiver"

7. The maximum speed of the "SPI" synchronous serial protocol is:
   (a) 100 kpbs (thousands of bits per second)
   (b) 1 Mbps (millions of bits per second)

(c) 2 Mbps
(d) 3 Mbps

8. To connect to a modern PC's RS-232 connector, you will need:
   (a) Fiber optic cable
   (b) 75 Ohm Coax and BNC connector
   (c) RJ-45 cable and crimper
   (d) A 9 pin male D-Shell connector

9. The RS-232 voltage levels of −12 volts for a "1" and +12 volts for "0" means that:
   (a) You can connect digital electronics devices directly to RS-232 connections
   (b) You can connect TTL/CMOS Logic drivers directly to RS-232
   (c) You can connect TTL/CMOS Logic inputs directly to RS-232
   (d) You cannot connect digital electronics devices directly to RS-232 connections

10. The MAX232:
   (a) Uses a charge pump to power the circuit
   (b) Requires +12 volts and −12 volts to convert TTL/CMOS Logic signals
   (c) Produces correct RS-232 voltages and converts TTL/CMOS Logic signals
   (d) Will allow a full RS-232 connection with only one chip

Test for Part Two

Do not refer to the text when taking this test. You may draw diagrams or use a calculator if necessary. A good score is at least 38 correct answers. Answers are in the back of the book. It's best to have a friend check your score the first time so you won't memorize the answers if you want to take the test again.

1. A signal with a 100 ns time "On" and a 230 ns time "Off" has a frequency of:
    (a) 30.3%
    (b) 3 GHz
    (c) 3 MHz
    (d) 3 kHz
2. A toggle flip flop will divide a clock frequency by:
    (a) The value selected in its inputs
    (b) 2
    (c) 1.5, but the output duty cycle is 50%
    (d) The toggle flip flop is used for debouncing switch inputs

Copyright © 2005 by The McGraw-Hill Companies, Inc. Click here for terms of use.

3. The NPN transistor relaxation oscillator is well suited for:
   (a) High-speed computer applications
   (b) Only audio applications
   (c) Low-cost applications where accuracy isn't important
   (d) Power supply duty cycle generators

4. If you wanted an oscillator that produced a period of 4 gate delays, you would:
   (a) Use a standard ring oscillator
   (b) Use something other than a ring oscillator
   (c) Use two three inverter ring oscillators and XOR their outputs
   (d) Use a two inverter ring oscillator and divide the output frequency by two using a toggle D flip flop

5. The duty cycle of a ring oscillator is:
   (a) Always 50%
   (b) Equal to the number of inverters used in the ring oscillator multiplied by the gate delay
   (c) Dependent on the technology used in the inverters
   (d) Always 100%

6. Why are TTL inverters not recommended for relaxation oscillators?
   (a) They are too costly
   (b) They do not operate at a fast enough speed
   (c) Their current controlled inputs will affect the operation of the oscillator
   (d) They may short out internally when used as part of an oscillator.

7. A relaxation oscillator has an R1 value of 1k, C of 0.1 μF and R2 equal to 10 k. What frequency will it oscillate at?
   (a) It won't oscillate
   (b) 4.54 kHz
   (c) 4.54 MHz
   (d) 4.54 Hz

8. Crystals used in oscillators are:
   (a) Relatively high cost but very accurate
   (b) Very robust and immune to shock damage
   (c) Low cost with an accuracy that is similar to that of a "canned oscillator"
   (d) Mined in South America

9. The crystal inverter circuit requires the following parts:
   (a) Crystal and inverter
   (b) Crystal, inverter, two capacitors and two resistors
   (c) Crystal, inductor, three resistors, two capacitors and an NPN transistor
   (d) Crystal, diode, two capacitors, hand wound coil, two diodes

10. Changing the voltage at the "Vcontrol" pin of a 555 astable oscillator:
    (a) Will change the period of the oscillator output
    (b) Won't change anything
    (c) Will lower the amount of power consumed
    (d) Will add unnecessary costs to the circuit

11. A 555 astable oscillator with $R1 = 47\,\text{k}$, $R2 = 100\,\text{k}$ and $C = 4.7\,\mu\text{F}$ will oscillate at:
    (a) 805 Hz
    (b) 0.805 Hz
    (c) 1.24 Hz
    (d) 1.24 kHz

12. Decreasing value of a resistor or capacitor in a 555 monostable will:
    (a) Lower its operating frequency
    (b) Raise its operating frequency
    (c) Increase the pulse width
    (d) Decrease the pulse width

13. A chip with two 555 timers built in has the part number:
    (a) 75555
    (b) 556
    (c) No such chip exists
    (d) 2x555

14. The delay in a "canned delay line" is produced by:
    (a) Elves
    (b) A piece of quartz, cut to provide a specified delay
    (c) A long piece of copper wire, formed as a coil
    (d) A large array of simple gates

15. Why is reset passed to the "Output Formatter" in the sequential circuit block diagram?
    (a) To control the operation of tri-state drivers built into the "Output Formatter"

(b) To synchronize outputs with the operation of the chip
(c) To minimize power usage when the chip is reset
(d) To speed up operation of the sequential circuit

16. To create a cascaded counter from multiple chips, what signal(s) are passed between the chips?
    (a) The most significant two bits
    (b) The "Carry" from the least significant counter and the "Borrow" from the more significant counter
    (c) Just the carry from the least significant counter to the clock input of the more significant counter
    (d) The clock and chip enable signals to be shared between the two counters

17. What are the disadvantages of serial data transmission over parallel data transmission?
    (a) Increased product chip count
    (b) Slower data transmission
    (c) Increased product power requirements
    (d) Increased data error rate

18. The linear feedback shift register polynomial defines:
    (a) The XOR "taps" used to modify the incoming data
    (b) The execution order of magnitude
    (c) The value needed to decode any value run through the LFSR
    (d) The relationship between the number of bits and speed of the LFSR's operation

19. The number of states and inputs in a hardware state machine are a function of:
    (a) The fanout capabilities of the chips used
    (b) The number of discrete states required
    (c) The requirements of the application
    (d) The size of the ROM used

20. Since commands to a Hitachi 44780 controlled LCD require 160 μs or more to execute, what is an effective way of waiting the suggested delay before sending the next command?
    (a) Using a 555 timer wired as a monostable
    (b) Passing requests to the LCD through an RC delay
    (c) Polling the busy flag
    (d) Using a clock with a 5 ms period

21. What signal is not included in a typical sequential logic circuit interface bus?
    (a) _Read
    (b) Data Read Ready
    (c) _Write
    (d) Address Bit 0

22. A "three to eight" decoder:
    (a) Cannot be implemented in TTL or CMOS Logic
    (b) Converts three data selects into eight device read requests
    (c) Converts three clock cycles into eight state machine addresses
    (d) Converts three binary bits into eight interface device selects

23. The segments to be turned on in a seven-segment LED display is determined by:
    (a) A circuit which enables the common cathodes or common anodes in the LED displays
    (b) A microprocessor built into each seven-segment LED display
    (c) A combinatorial circuit performing Boolean arithmetic operations on the display bits
    (d) A sequential circuit that compares the display bits to expected values

24. A PWM with a period of 10 μs and a "high" signal of 4 μs has a duty cycle of:
    (a) Not enough information is available to determine the duty cycle
    (b) 60%
    (c) 0.4
    (d) 40%

25. To produce a PWM output signal of 20 kHz and have 6 bits of accuracy, what input clock frequency should be used?
    (a) 20 kHz
    (b) 64 Hz
    (c) 1.28 MHz
    (d) 5.1 MHz

26. The two inverter debounce circuit is best suited for what kind of input devices?
    (a) Push buttons
    (b) 40%

(c) 0.4
(d) Double throw switches

27. Hysteresis causes logic inputs to be registered:
(a) Faster than normal inputs
(b) At lower thresholds than devices with standard inputs
(c) At more extreme thresholds than devices with standard inputs
(d) When there is an inductor on the line

28. A switch matrix keypad is:
(a) Used by Trinity and Neo to access the Matrix
(b) A two-dimensional array of switches used to provide multiple button inputs
(c) A series of switches that change the output signal of a sequential circuit
(d) The natural evolution of a single button to multiple buttons

29. The Princeton architecture was criticized because:
(a) The single memory interface was felt to be a performance bottleneck
(b) It relied too heavily on vacuum tube technology
(c) The design was taken from other, earlier computer designers
(d) The amount of space required for it seemed to be prohibitive

30. The first digit to the right of the decimal point in a binary floating point number has a value of:
(a) 0.1 decimal
(b) 0.25 decimal
(c) 0.5 decimal
(d) 1.0 decimal

31. Floating point numbers are stored in data size except:
(a) 2 bytes
(b) 4 bytes
(c) 8 bytes
(d) 10 bytes

32. SRAM memory is best suited for applications which require:
(a) Data stacks
(b) Gigabytes of memory
(c) Mass storage of data
(d) Fast data access for a relatively large memory area

33. Stacks cannot be modeled by:
    (a) Trays in a lunchroom
    (b) Pieces of paper on a person's desk
    (c) Stacks of paper produced by a computer processor
    (d) A jelly bean jar

34. The operation of the Zener regulator is analogous to:
    (a) A car's carburetor
    (b) A bowl with a hole cut in the bottom
    (c) A PWM output driven by a comparator
    (d) A comparator output driven by sensor

35. The operation of the linear regulator is analogous to:
    (a) A car's carburetor
    (b) A bowl with a hole cut in the bottom
    (c) A PWM output driven by a comparator
    (d) A comparator output driven by sensor

36. A 10:1 transformer has an input of 110 volts AC. What is its output?
    (a) 11 volts DC
    (b) 11 volts AC
    (c) 110 volts DC
    (d) 11 amps AC

37. "PAL" I/O pins are:
    (a) Input and Output
    (b) Programmable Input or Output
    (c) Input only
    (d) Output only

38. What is not a "local memory" device:
    (a) Processor cache
    (b) PCI status registers
    (c) Main memory (S)DRAM
    (d) Processor ROM

39. The Logic levels for the PC's parallel port are?
    (a) 3.3 volt CMOS Logic compatible
    (b) 5 volt TTL/CMOS Logic compatible
    (c) 5 volt "HCT" Logic compatible
    (d) Current controlled, voltage levels are not considered

40. The inventor of the parallel port pinout standard was:
    (a) IBM
    (b) Apple Computers
    (c) The Centronics Corporation
    (d) Xerox FARC

41. The ‘‘Data’’ bits of the PC’s parallel port have what kind of outputs?
    (a) Discrete transistors
    (b) CMOS totem pole outputs
    (c) Pulled up Open Collectors that can be changed by external devices
    (d) TTL tri-state buffers

42. ‘‘Vertical synch’’ in a video display:
    (a) Moves the electron beam in the CRT to the left
    (b) Moves the electron beam in the CRT to the top
    (c) Starts the raster going up and down
    (d) Is needed for CRTs pointing upwards

43. The ‘‘NTSC’’ video standard was first developed for:
    (a) Military radar screens
    (b) Portable news gathering services
    (c) Electronic instruments
    (d) Televisions

44. The ‘‘Microwire’’ synchronous serial protocol sends:
    (a) A word consisting of 16 bits of data
    (b) A word consisting of 8 bits of data
    (c) Status Information before Data
    (d) Command Information before Data

45. I2C’s ‘‘Acknowledge’’ bit:
    (a) Is used as a ‘‘Parity Bit’’ for Received Data
    (b) Indicates the Received Data was Valid
    (c) Is a placeholder in case 9 bits of data is required
    (d) Is not currently implemented, but will be in the future

46. Baudot asynchronous serial communications was developed for:
    (a) Networking
    (b) Televisions
    (c) Teletypes
    (d) Telegraphs

47. What are the differences between Baudot asynchronous serial communications and NRZ serial communications?
    (a) None
    (b) The number of bits transmitted
    (c) The speed at which data is transmitted
    (d) The number of "overhead" bits

48. The primary difference between Manchester Encoding and NRZ is:
    (a) The media used to transmit the data
    (b) The bit timing for "0" and "1" change in Manchester Encoding
    (c) The data rates used to transmit the data
    (d) The companies that hold the original patents on the technologies

49. To implement a three wire RS-232 connection, you will have to tie together:
    (a) RTS/CTS and DSR/DTR
    (b) RI/CTS and DSR/RTS
    (c) DCD/DSR and RTS/CTS
    (d) DCD/CTS and RI/DSR

50. The RS-232 to TTL/CMOS level translator shown in Fig. Test 2.1:
    (a) Is an inexpensive, full capability RS-232 interface
    (b) Sends data in "half duplex" mode only
    (c) Can be used for handshaking lines as well as RX and TX
    (d) Is limited by the speed it can operate at

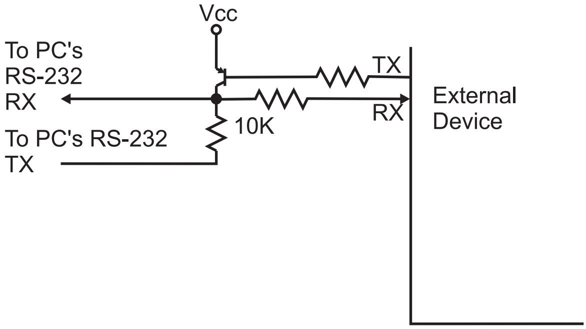

Fig. Test 2-1.

Final Exam

Do not refer to the text when taking this test. You may draw diagrams or use a calculator if necessary. A good score is at least 75 correct answers. Answers are in the back of the book. It’s best to have a friend check your score the first time so you won’t memorize the answers if you want to take the test again.

1. The NAND Gate is the base technology for:
   (a) TTL logic circuits
   (b) Your TV set
   (c) Computer chips
   (d) Symbolic logic

2. What is not an indicator for an Inverted bit?
   (a) “!”
   (b) “_”
   (c) “^”
   (d) “-”

3. Combinatorial logic is used:
   (a) In a DJ’s mixing table to combine audio inputs together with special effects
   (b) To produce a desired output from a specific set of inputs
   (c) To express the mathematics of cryptography
   (d) To collate data from different sources

Copyright © 2005 by The McGraw-Hill Companies, Inc. Click here for terms of use.

4. The following truth table represents the following basic gate:

Input "A"	Input "B"	Output
0	0	0
0	1	1
1	1	0
1	0	0

(a) AND
(b) OR
(c) NOT
(d) None

5. The following truth table can be represented as the sum of products:

Input "A"	Input "B"	Input "C"	Output
0	0	0	0
0	0	1	0
0	1	1	1
0	1	0	0
1	1	0	0
1	1	1	0
1	0	1	0
1	0	0	1

(a) $(A \cdot B \cdot C) + (!A + !B + !C)$
(b) $(!A \cdot B \cdot C) + (!A + !B + !C)$
(c) $(!A \cdot B \cdot C) + (A + !B + !C)$
(d) $(A \cdot !B \cdot C) + (A + !B + !C)$

6. The following truth table can be represented as the product of sums:

Input "A"	Input "B"	Input "C"	Output
0	0	0	0
0	0	1	1
0	1	1	1
0	1	0	1
1	1	0	1
1	1	1	0
1	0	1	1
1	0	0	1

(a) $(!A + !B + !C) \cdot (A + B + C)$
(b) $(!A + !B + C) \cdot (A + B + C)$
(c) $(!A + !B + !C) \cdot (A + !B + C)$
(d) $(!A + B + !C) \cdot (A + B + C)$

7. Oscilloscopes are used for:
(a) Testing the impedance of a circuit trace
(b) Display the state of multiple signals
(c) Displaying the current voltage of individual signals
(d) Displaying the analog voltage of individual signals

8. According to the AND associative law, which equation is true?
(a) $(A + B) + C = A + (B + C) = A + B + C$
(b) $A \cdot (B + C) = (A \cdot B) + (A \cdot C)$
(c) $A + (B \cdot C) = (A + B) \cdot (A + C)$
(d) $!(A + B) = !A \cdot !B$

9. A CMOS logic technology has a gate delay of 25 ns and an AND statement built from it requires two gate delays for the signal to pass through it. How long will it take a signal to pass through the AND gate?
(a) 0 ns
(b) 25 ns

(c) 50 ns
(d) Indeterminate

10. The first step in reducing the following truth table is:

Input "A"	Input "B"	Input "C"	Output
0	0	0	0
0	0	1	0
0	1	1	1
0	1	0	1
1	1	0	0
1	1	1	1
1	0	1	1
1	0	0	0

(a)

Input "A"	Input "B"	Input "C"	Output
0	0	0	0
0	0	1	0
0	1	x	1
1	1	0	0
1	x	1	1
1	0	0	0

(b)

Input “A”	Input “B”	Input “C”	Output
0	0	0	0
0	0	1	0
0	1	x	1
1	1	0	0
1	1	1	1
1	0	1	1
1	0	0	0

(c)

Input “A”	Input “B”	Input “C”	Output
0	0	0	0
0	0	1	0
0	1	1	1
x	1	0	1
1	1	1	1
1	0	1	1
1	0	0	0

(d)

Input "A"	Input "B"	Input "C"	Output
0	0	0	0
0	0	1	0
0	1	1	1
0	1	0	1
1	1	0	0
x	1	1	1
1	0	0	0

11. Using De Morgan's NAND Theorem. "!(!A · !B)" is equal to:
    (a) A + B
    (b) !A + !B
    (c) !(A · B)
    (d) A · B

12. The sum of products logic equation

    `Output` $= ($`!A · B · !C`$) + ($`!A · !B · !C`$)$

    can be reduced to:

    (a) A · C
    (b) !A · !C
    (c) !C · CB
    (d) C

13. A Karnaugh map has three bits equal to 1, can one circle (and one AND statement) be used to represent the logic function?
    (a) Yes
    (b) Yes, if inverters can be used
    (c) Yes, if an XOR gate could be used
    (d) No

14. The four bit Karnaugh map

	AB			
	00	01	11	10
CD-00	0	1	1	1
01	0	1	0	0
11	0	1	0	0
10	0	1	1	1

has the optimized sum of product equation:

(a) Output = (!B · !D) + (!A · !B)
(b) Output = (A · B) + (A · D)
(c) Output = (!B · A) + (B · D)
(d) Output = (!A · B) + (A · !D)

15. The NAND equivalent to an OR gate is:
(a) Built from two NAND gates and requires three gate delays for a signal to pass through
(b) Built from two NAND gates and requires two gate delays for a signal to pass through
(c) Built from three NAND gates and requires two gate delays for a signal to pass through
(d) Built from one NOR gate as well as a NOT gate and requires two gate delays for a signal to pass through

16. The voltage drop across a resistor in a parallel circuit:
(a) Is the same as the applied voltage
(b) Is proportional to the power dissipated in the circuit
(c) Is always zero
(d) Is proportional to the resistor's value relative to the total resistance in the circuit multiplied by the applied voltage

17. A 47μF capacitor:
(a) Has a value of 47 trillionths of a farad.
(b) Weighs 47 micrograms
(c) Probably uses polyester as a dielectric
(d) Has a value of 0.000047 farads

18. The equivalent resistance of a 10 ohm resistor in parallel with 10 ohm and 20 ohm resistors in series is:
    (a) 40 ohms
    (b) 30 ohms
    (c) 7.5 ohms
    (d) 6.7 ohms

19. In a PNP bipolar transistor, collector current:
    (a) Flows into the emitter through to the collector
    (b) Is dependent on the emitter current
    (c) Is negative with respect to the power source
    (d) Like in the NPN bipolar transistor, does not include the base current

20. CMOS Logic is:
    (a) Sound controlled
    (b) Resistor controlled
    (c) Current controlled
    (d) Voltage controlled

21. "Breadboards" allow:
    (a) Delivery of bagels and other breakfast foods without any garbage
    (b) Simple creation of electronic products that can be delivered to consumers
    (c) The method that provides the fastest signal paths for digital electronics circuits
    (d) Simple creation of prototype circuits

22. The holes in a breadboard:
    (a) Allow effective cooling of the breadboard circuitry
    (b) Allow components to be mounted and interconnected
    (c) Are there simply for aesthetics
    (d) Minimize the resistance encountered by signals

23. A circuit that would provide valid TTL and CMOS logic inputs would:
    (a) Both source current as well as provide high and low voltages
    (b) Both provide high voltage as well as sink and source current
    (c) Both provide low voltage as well as sink and source current
    (d) Both sink current as well as provide high and low voltages

24. The four bit binary number B’1010 1101’ expressed as a hexadecimal number is:
(a) 171
(b) 0x0AB
(c) 0x02231
(d) 0x0171

25. The most significant digit in the decimal number “1234” is:
(a) 1
(b) 2
(c) 3
(d) 4

26. The decimal number “42” in hexadecimal is:
(a) 0x042
(b) B’0010 0100’
(c) 2A
(d) 0x02A

27. The four bit hexadecimal number 0x0F4EA expressed in decimal is:
(a) −2,838
(b) 62,698
(c) B’1111 0100 1110 1010’
(d) 29.930

28. B’0101’ in binary, using the formula Gray code $=$ Binary ˆ (Binary$\gg$1) can be converted to the Gray code:
(a) B’1010’
(b) B’0110’
(c) B’0111’
(d) B’1110’

29. The Gray code B’1010’ corresponds to the binary value
(a) B’1111’
(b) B’1110’
(c) B’1101’
(d) B’1010’

30. A “Carry Look-Ahead” adder:
(a) Is the only way addition should be carried out in digital electronics
(b) Is often needlessly complex for most applications
(c) Produces its result in an amount of time independent of the number of bits

(d) Produces its result in an amount of time dependent on the number of bits

31. In a universe where infinity (the highest possible number) is one thousand (1,000); "−34" could be represented as:
    (a) Only −34
    (b) 966
    (c) 976
    (d) 34

32. Converting the eight bit, two's complement value "−124" to a positive number by inverting each bit and incrementing the result produces the bit pattern:
    (a) B'0111 1100'
    (b) Which is seven bits long and is invalid
    (c) B'1000 0100'
    (d) B'01111 110'

33. Multiplying two eight bit numbers by repeated addition:
    (a) Will require up to 8 addition operations
    (b) Will require up to 255 addition operations
    (c) Cannot be implemented in digital electronics
    (d) Is the fastest way of performing binary multiplication

34. Multiplying a binary number by 64 can be accomplished by:
    (a) Clearing the least significant six bits
    (b) Shifting left six bits
    (c) Shifting right six bits
    (d) Setting the least significant six bits

35. What is the best method of multiplying binary number B'0110 1101' by B'0011 1110'?
    (a) Boothe's algorithm: shift B'0110 1101' to the left by 7 and subtract B'0110 1101 from the result
    (b) Shifting left seven bits according to Boothe's algorithm
    (c) Shifting right six bits according to Boothe's algorithm
    (d) Boothe's algorithm: shift B'0110 1101' to the right by 7 and subtract B'0110 1101 from the result

36. If you looked up the "gate delay" specification for the technology used to build an AND gate chip, what would the chip's gate delay be?
    (a) Exactly what is listed for the technology used by the AND gate chip
    (b) Dependent on whether or not the chip technology is NOR or NAND gate based
    (c) Twice the listed gate delay
    (d) Three times the listed gate delay

37. What tools should *not* be used to find a possible race condition in a circuit?
    (a) An oscilloscope
    (b) A logic analyzer
    (c) A logic simulator
    (d) A time delay reflectometer

38. A chip fanout of 6 means:
    (a) The chip's output can drive six inputs
    (b) The chip provides six outputs for a single input
    (c) There can be six chips connected to the various outputs
    (d) The chip provides six outputs, each one a variation on the inputs

39. When working with TTL, the Mickey Mouse "AND" circuit should have a resistor value of:
    (a) The Mickey Mouse AND gate will not work with TTL
    (b) 4 watts
    (c) 10 k
    (d) 470 Ω

40. Can a pulled up button (which pulls to ground) be attached to a dotted AND bus?
    (a) Yes, if the signal passes through an open collector transistor
    (b) Yes, if the signal passes through a gate with an open collector driver
    (c) Unconditionally, yes
    (d) No

41. Can a totem pole driver be attached to a dotted AND bus?
    (a) Yes, if the power to the chip with the totem pole driver is the same as the chips on the dotted AND bus
    (b) Yes, if care is taken to ensure grounds are kept at the same voltage level

(c) Unconditionally, yes
(d) No

42. When the TTL input is pulled low, how much current flows out of the pin?
(a) 1 μA
(b) 100 μA
(c) 1 mA
(d) No current at all

43. The most popular output driver type found in logic chips is:
(a) The totem pole driver
(b) Tri-state driver
(c) Open collector
(d) Open drain

44. A commercial microprocessor reset chip will:
(a) Pull the microprocessor's _Reset line low at power up and when its input voltage falls below a set value
(b) Drive the microcontroller's _Reset line high at power up and when its input voltage falls below a set value
(c) Pull the microprocessor's _Reset line low at power up.
(d) Turn on a LED when its input voltage falls below a set value to indicate a power supply problem

45. A small triangle on the input of a sequential device indicates:
(a) The pin is buffered before being processed within the chip
(b) The signal is inverted before being processed within the chip
(c) The signal is a clock to the chip's internal flip flops
(d) The circuitry connected to the chip was either not completed or qualified and it should be used with caution

46. Which formula approximates the time required for an RC network to change state due to a sudden voltage?
(a) $t = 2.2 \times R \times C$
(b) $t = -RC \times \ln(Vcc)$
(c) $t = -RC \times \ln(Vcc - (Vcc \times e^{-1/RC}))$
(d) $t = V \times i$

47. A switch bounces:
(a) Never
(b) Most of the time, but this can be filtered out with a capacitor
(c) Only if it is not feeding the input of a flip flop
(d) Always

48. The NOR "RS" flip flop saves data when the inputs are:
    (a) R = 0, S = 0
    (b) R = 0, S = 1
    (c) R = 1, S = 1
    (d) R = 1, S = 0

49. The NAND "RS" flip flop sets the output (drives out "1") when the inputs are:
    (a) R = 0, S = 0
    (b) R = 0, S = 1
    (c) R = 1, S = 1
    (d) R = 1, S = 0

50. Reset circuitry for sequential circuits should be used:
    (a) Always
    (b) Only for digital clocks to avoid the clock starting up at a random time
    (c) In situations where the start up values are critical
    (d) Never

51. A signal with a 100 ns time "On" and a 230 ns time "Off" has a frequency of:
    (a) 30.3%
    (b) 3 GHz
    (c) 3 MHz
    (d) 3 kHz

52. A toggle flip flop will divide a clock frequency by:
    (a) The value selected in its inputs
    (b) 2
    (c) 1.5, but the output duty cycle is 50%
    (d) The toggle flip flop is used for debouncing switch inputs

53. The NPN transistor relaxation oscillator is well suited for:
    (a) High-speed computer applications
    (b) Only audio applications
    (c) Low-cost applications where accuracy isn't important
    (d) Power supply duty cycle generators

54. If you wanted an oscillator that produced a period of 4 gate delays, you would:
    (a) Use a standard ring oscillator
    (b) Use something other than a ring oscillator
    (c) Use a two three inverter ring oscillators and XOR their outputs

(d) Use a two inverter ring oscillator and divide the output frequency by two using a toggle D flip flop

55. The duty cycle of a ring oscillator is:
    (a) Always 50%
    (b) Equal to the number of inverters used in the ring oscillator multiplied by the gate delay
    (c) Dependent on the technology used in the inverters
    (d) Always 100%

56. Why are TTL inverters not recommended for relaxation oscillators?
    (a) They are too costly
    (b) They do not operate at a fast enough speed
    (c) Their current controlled inputs will affect the operation of the oscillator
    (d) They may short out internally when used as part of an oscillator

57. A relaxation oscillator has an R1 value of 1 k, C of 0.1 μF and R2 equal to 10 k. What frequency will it oscillate at?
    (a) It won't oscillate
    (b) 4.54 kHz
    (c) 4.54 MHz
    (d) 4.54 Hz

58. Crystals used in oscillators are:
    (a) Relatively high cost but very accurate
    (b) Very robust and immune to shock damage
    (c) Low cost with an accuracy that is similar to that of a "canned oscillator"
    (d) Mined in South America

59. The crystal inverter circuit requires the following parts:
    (a) Crystal and inverter
    (b) Crystal, inverter, two capacitors and two resistors
    (c) Crystal, Inductor, three resistors, two capacitors and an NPN transistor
    (d) Crystal, diode, two capacitors, hand wound coil, two diodes

60. Changing the voltage at the "Vcontrol" pin of a 555 astable oscillator:
    (a) Will change the period of the oscillator output
    (b) Won't change anything

(c) Will lower the amount of power consumed
(d) Will add unnecessary costs to the circuit

61. A 555 astable oscillator with $R1 = 47\,k$, $R2 = 100\,k$ and $C = 4.7\,\mu F$ will oscillate at:
    (a) 805 Hz
    (b) 0.805 Hz
    (c) 1.24 Hz
    (d) 1.24 kHz

62. Decreasing value of a resistor or capacitor in a 555 monostable will:
    (a) Lower its operating frequency
    (b) Raise its operating frequency
    (c) Increase the pulse width
    (d) Decrease the pulse width

63. A chip with two 555 timers built in has the part number:
    (a) 75555
    (b) 556
    (c) No such chip exists
    (d) 2 × 555

64. The delay in a "canned delay line" is produced by:
    (a) Elves
    (b) A piece of quartz, cut to provide a specified delay
    (c) A long piece of copper wire, formed as a coil
    (d) A large array of simple gates

65. Why is reset passed to the "Output Formatter" in the sequential circuit block diagram?
    (a) To control the operation of tri-state drivers built into the "Output Formatter"
    (b) To synchronize outputs with the operation of the chip
    (c) To minimize power usage when the chip is reset
    (d) To speed up operation of the sequential circuit

66. To create a cascaded counter from multiple chips, what signal(s) are passed between the chips?
    (a) The most significant two bits
    (b) The "Carry" from the least significant counter and the "Borrow" from the more significant counter
    (c) Just the carry from the least significant counter to the clock input of the more significant counter

(d) The clock and chip enable signals to be shared between the two counters

67. What are the disadvantages of serial data transmission over parallel data transmission?
    (a) Increased product chip count
    (b) Slower data transmission
    (c) Increased product power requirements
    (d) Increased data error rate

68. The linear feedback shift register polynomial defines:
    (a) The XOR "taps" used to modify the incoming data
    (b) The execution order of magnitude
    (c) The value needed to decode any value run through the LFSR
    (d) The relationship between the number of bits and speed of the LFSR's operation

69. The number of states and inputs in a hardware state machine are a function of:
    (a) The fanout capabilities of the chips used
    (b) The number of discrete states required
    (c) The requirements of the application
    (d) The size of the ROM used

70. A constant delay of 100 µs can be used for instruction and data writes to the 44780 controlled LCD except when:
    (a) Writing the "Cursor Move" instruction
    (b) When scrolling the LCD upwards
    (c) When writing the "Screen Clear" and "Cursor Home" commands
    (d) Backspacing from the start of the current line to the start of the next

71. What signal is not included in a typical sequential logic circuit interface bus?
    (a) _Read
    (b) Data Read Ready
    (c) _Write
    (d) Address Bit 0

72. A "three to eight" decoder:
    (a) Cannot be implemented in TTL or CMOS Logic
    (b) Converts three data selects into eight device read requests
    (c) Converts three clock cycles into eight state machine addresses
    (d) Converts three binary bits into eight interface device selects

73. The segments to be turned on in a seven-segment LED display is determined by:
    (a) A circuit which enables the common cathodes or common anodes in the LED displays
    (b) A microprocessor built into each seven-segment LED display
    (c) A combinatorial circuit performing Boolean arithmetic operations on the display bits
    (d) A sequential circuit that compares the display bits to expected values

74. A PWM with a period of 10 µs and a "high" signal of 4 µs has a duty cycle of:
    (a) Not enough information is available to determine the duty cycle
    (b) 60%
    (c) 0.4
    (d) 40%

75. To produce a PWM output signal of 20 kHz and have 6 bits of accuracy, what input clock frequency should be used?
    (a) 20 kHz
    (b) 64 Hz
    (c) 1.28 MHz
    (d) 5.1 MHz

76. The two inverter debounce circuit is best suited for what kind of input devices?
    (a) Push buttons
    (b) 40%
    (c) 0.4
    (d) Double throw switches

77. Hysteresis causes logic inputs to be registered:
    (a) Faster than normal inputs
    (b) At lower thresholds than devices with standard inputs
    (c) At more extreme thresholds than devices with standard inputs
    (d) When there is an inductor on the line

78. A switch matrix keypad is:
    (a) Used by Trinity and Neo
    (b) A two-dimensional array of switches used to provide multiple button inputs

(c) A series of switches that change the output signal of a sequential circuit
(d) The natural evolution of a single button to multiple buttons

79. The Princeton architecture was criticized because:
   (a) The single memory interface was felt to be a performance bottleneck
   (b) It relied too heavily on vacuum tube technology
   (c) The design was taken from other, earlier computer designers
   (d) The amount of space required for it seemed to be prohibitive

80. The first digit to the right of the decimal point in a binary floating point number has a value of:
   (a) 0.1 decimal
   (b) 0.25 decimal
   (c) 0.5 decimal
   (d) 1.0 decimal

81. Floating point numbers are stored in data size except:
   (a) 2 bytes
   (b) 4 bytes
   (c) 8 bytes
   (d) 10 bytes

82. SRAM memory is best suited for applications which require:
   (a) Data stacks
   (b) Gigabytes of memory
   (c) Mass storage of data
   (d) Fast data access for a relatively large memory area

83. Stacks cannot be modeled by:
   (a) Trays in a lunchroom
   (b) Pieces of paper on a person's desk
   (c) Stacks of paper produced by a computer processor
   (d) A jelly bean jar

84. The operation of the Zener regulator is analogous to:
   (a) A car's carburetor
   (b) A bowl with a hole cut in the bottom
   (c) A PWM output driven by a comparator
   (d) A comparator output driven by sensor

85. The operation of the linear regulator is analogous to:
   (a) A car's carburetor

(b) A bowl with a hole cut in the bottom
(c) A PWM output driven by a comparator
(d) A comparator output driven by sensor

86. A 10:1 transformer has an input of 110 volts AC. What is its output?
(a) 11 volts DC
(b) 11 volts AC
(c) 110 volts DC
(d) 11 amps AC

87. "PAL" I/O pins are:
(a) Input and Output
(b) Programmable Input or Output
(c) Input only
(d) Output only

88. What is not a "local memory" device:
(a) Processor cache
(b) PCI status registers
(c) Main memory (S)DRAM
(d) Processor ROM

89. The Logic levels for the PC's parallel port are?
(a) 3.3 volt CMOS Logic compatible
(b) 5 volt TTL/CMOS Logic compatible
(c) 5 volt "HCT" Logic compatible
(d) Current controlled, voltage levels are not considered

90. The inventor of the parallel port pinout standard was:
(a) IBM
(b) Apple Computers
(c) The Centronics Corporation
(d) Xerox PARC

91. The "Data" bits of the PC's parallel port have what kind of outputs?
(a) Discrete transistors
(b) CMOS totem pole outputs
(c) Pulled up Open Collectors that can be changed by external devices
(d) TTL tri-state buffers

92. "Vertical synch" in a video display:
    (a) Moves the electron beam in the CRT to the left
    (b) Moves the electron beam in the CRT to the top
    (c) Starts the raster going up and down
    (d) Is needed for CRTs pointing upwards

93. The "NTSC" video standard was first developed for:
    (a) Military radar screens
    (b) Portable news gathering services
    (c) Electronic instruments
    (d) Televisions

94. The "Microwire" synchronous serial protocol sends:
    (a) A word consisting of 16 bits of data
    (b) A word consisting of 8 bits of data
    (c) Status Information before Data
    (d) Command Information before Data

95. I2C's "Acknowledge" bit:
    (a) Is used as a "Parity Bit" for Received Data
    (b) Indicates the Received Data was Valid
    (c) Is a placeholder in case 9 bits of data is required
    (d) Is not currently implemented, but will be in the future

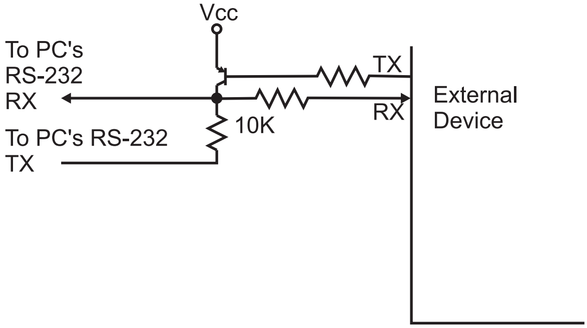
96. Baudot asynchronous serial communications was developed for:
    (a) Networking
    (b) Televisions
    (c) Teletypes
    (d) Telegraphs

97. What are the differences between Baudot asynchronous serial communications and NRZ serial communications?
    (a) None
    (b) The number of bits transmitted
    (c) The speed at which data is transmitted
    (d) The number of "overhead" bits

98. The primary difference between Manchester Encoding and NRZ is:
    (a) The media used to transmit the data
    (b) The bit timing for "0" and "1" change in Manchester Encoding
    (c) The data rates used to transmit the data

99. To implement a three wire RS-232 connection, you will have to tie together:
    (a) RTS/CTS and DSR/DTR
    (b) RI/CTS and DSR/RTS
    (c) DCD/DSR and RTS/CTS
    (d) DCD/CTS and RI/DSR

100. The RS-232 to TTL/CMOS level translator shown in Figure Final Exam 1:
    (a) Is an inexpensive, full capability RS-232 interface.
    (b) Send data in ''half duplex'' mode only
    (c) Can be used for handshaking lines as well as RX and TX
    (d) Is limited by the speed it can operate at



Vcc
To PC's RS-232 RX
To PC's RS-232 TX
10K
TX
RX
External Device

Fig. Final Exam-1.

Appendix: Answers to Quiz, Tests, and Final Exam

Chapter 1:
1. b 2. a 3. c 4. a 5. d

Donald Lee Smith

Don Smith is elderly and has suffered several serious strokes in the last few years. He is no longer able to respond to e-mails and his web site has been taken over by people who appear very keen to ensure that his work and information can no longer be accessed by members of the public.

At this point in time there is very little information available on Don's achievements. What I have been able to locate is four video recordings of lectures which he gave, plus a copy of his pdf document entitled "Resonance Energy Systems". There is also a web site with limited information. This site appears to have been set up by Don's son whom I suspect does not fully understand how his father's devices work. Don has produced at least forty eight different devices which draw energy from what Don prefers to call "the ambient background". His devices are capable of supplying kilowatts of excess energy and in most cases they do not require any input energy to be supplied by the user.

It is said that 40,000 copies of Don's pdf document have been sold worldwide, but it appears that it is no longer possible to buy a copy, and for that reason, a copy is contained within this document. Please be aware that Don states quite openly that he does not disclose all of the details on any of his devices in his public discussions. This is because the rights to each device have been assigned to a different company in which Don has a financial interest, and so it is not in his interests to disclose the full details. However, ha says that he discloses enough for somebody who is experienced in radio-frequency electronics to be able to deduce the things which he does not disclose and so build a device for his own use. If that is the case, then anybody who has succeeded in doing so has kept very quiet about it afterwards (which is understandable). Having said that, Tariel Kapanadze of Georgia appears to have replicated one of the designs although it is quite likely that Tariel deduced the operating principles for himself. These principles are clearly based on the work of Nikola Tesla.

In Don's work, he refers to the educational kit entitled "Resonant Circuits" No 10 - 416 from The Science Source at www.thesciencesiource.com. That kit now costs US$100 and they don't mention the fact that you need a signal generator capable of producing a 10 volt output at up to 1 MHz in order to be able to do resonance tests, and the kit now uses an LED rather than a neon bulb.

There is a "book" of Don's entitled "An Answer to America's Energy Deficit" but, being an earlier work than his pdf document, it does not appear to contain anything extra of any significance. Here is Don's pdf document, in it's original American-language wording with just minor clerical corrections:

DIPOLE TRANSFORMER GENERATOR
DESCRIPTION

TECHNICAL FIELD:

The Invention relates to loaded Dipole Antenna Systems and their Electromagnetic radiation. When used as a transformer with an appropriate energy collector system it becomes a transformer generator. The invention collects and converts energy which, with conventional devices, is radiated and wasted.

BACKGROUND ART:

An International search of Patent Databases for closely related methods did not reveal any prior Art with an Interest in conserving radiated and wasted magnetic waves as useful energy.

DISCLOSURE OF INVENTION:

The Invention is a new and useful departure from transformer generator construction, such that radiated and wasted magnetic energy changes into useful electrical energy. Gauss Meters show that much energy from conventional electromagnetic devices is radiated back into the ambient background and wasted. In the case of conventional transformer generators, a radical change in the physical construction, allows better access to the energy available. It is found that creating a dipole and Inserting capacitor plates at right angle to the current flow, allows magnetic waves to change back to useful electrical (coulombs) energy. Magnetic waves passing through the capacitor plates do not degrade and the full impact of the available energy is accessed. One, or many sets of capacitor plates, may be used as desired. Each set of plates makes an exact copy of the full force and effect of the energy present in the magnetic waves. The originating source is not depleted or degraded as is common in conventional transformers.

BRIEF DESCRIPTION OF THE DRAWINGS:

The Dipole at right angle allows the magnetic flux surrounding it to intercept the capacitor plate, or plates, at right angles. The electrons present are spun in such a way that the electrical component of the electrons is collected by the capacitor plates. Essential parts are the South and North component of an active Dipole. Examples presented here, exist as fully functional prototypes, and were engineer constructed and fully tested for utility by the Inventor. Corresponding parts are utilized in each of the three examples as shown in the Drawings.

DRAWING 1 OF 4: VIEW OF THE METHOD

N = North and S = South of the Dipole

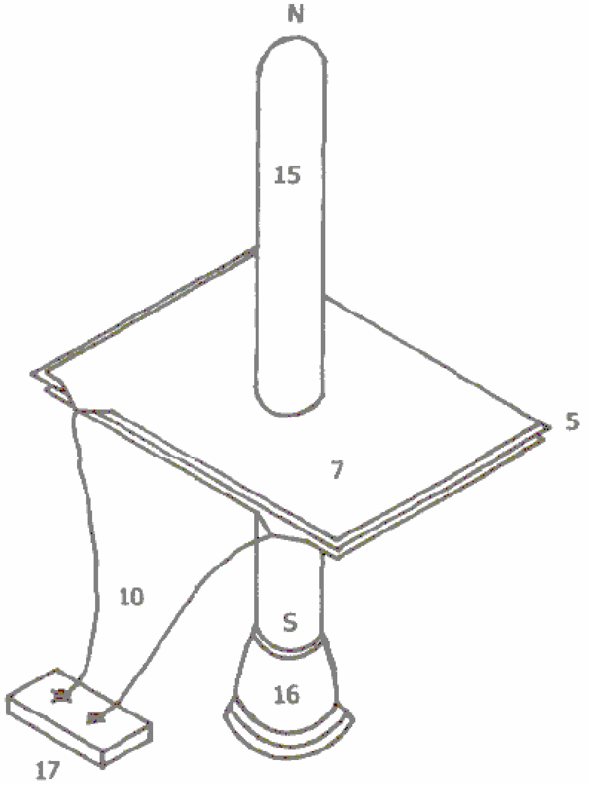
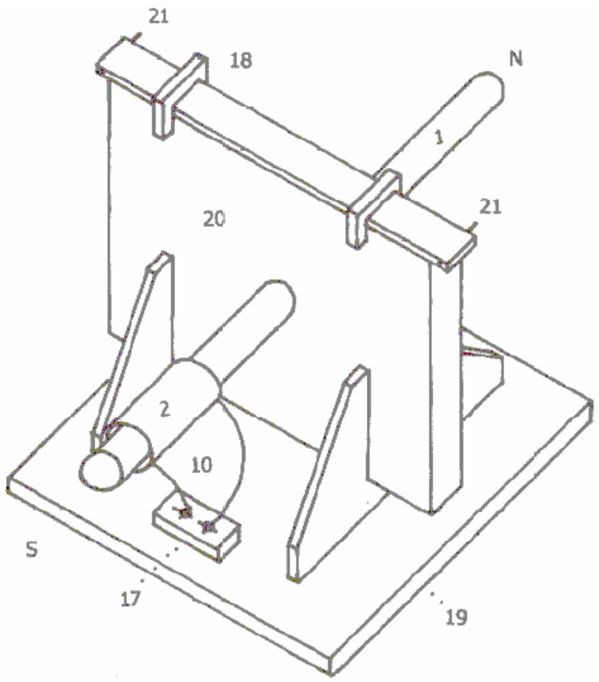
N = North and S = South Components of the active Dipole.



5. Dielectric separator of the capacitor plates.
7. Upper capacitor plate: upper plate is aluminum and lower plate is copper.
10. Connector wires.
15. Plasma Tube, 4 feet long and 6 inches in diameter.
16. High Voltage Energy source for the active Plasma Dipole.
17. Connector block: outlet for testing and use.

DRAWING 4 OF 4: Manufactures Prototype, Constructed and fully tested.



1. Metal Dipole rod.
2. Resonate High Voltage induction coil.
10. Connector wires.
17. Connector block for Input from high voltage energy source.
18. Clamps for upper edge of capacitor packet.
19. Support Device for The Dipole Transformer Generator.
20. Packet of Capacitor Plates.
21. Output connectors of the capacitor, producing energy into a deep cycle battery which then powers the inverter.

BEST METHOD OF CARRYING OUT THE INVENTION:

The Invention is applicable to any and all electrical energy requirements. The small size and high efficiency makes It an attractive option. It is particularly attractive for remote areas, homes, office buildings, factories, shopping centers, public places, transportation, water systems, electric trains, boats, ships and all things small or great Construction materials are readily available and the skill level required is moderate.

CLAIMS:

1. Radiated magnetic flux from the Dipole, when intercepted by capacitor plates at right angles, changes to useful electrical energy.
2. A Device and method for converting for use, normally wasted electromagnetic energy.
3. The Dipole of the Invention is any resonating substance such as Metal Rods, Coils and Plasma Tubes which have interacting Positive and Negative Components.
4. The Resulting Heaviside current component Is changed to useful electrical energy.

ABSTRACT

An Electromagnetic Dipole Device and Method, wherein, radiated and wasted energy is transformed into useful energy. A Dipole as seen in Antenna Systems is adapted for use with capacitor plates such that the Heaviside Current Component becomes a useful source of electrical energy.

Web-site: altenergy-pro.com
E-mail: donsm1@earthlink.net

Dear Reader:

TransWorld Energy is dedicated to improving the Human Condition in the Field of Energy which, at the same time, makes possible Healthy Water and increases the food Supply. A never-ending source of energy found throughout the universe is easily accessed with the minimum of effort and cost. The technology for doing this has been around since the 1820s. Selfish special interests have made sure that the technology remains discredited. People who control the Energy Sources control the World.

Extensive research and development by TransWorld and Associates has been progressing for more than 15 years. Numerous successful Energy Producing Devices have been produced and demonstrated throughout the World. Some of these can be viewed by the Web Site located using any major search engine (such as Lycos, Yahoo, Altavista, NorthenLight and more than 2,000 others throughout the World).

The Book which You are viewing has more than 40,000 copies in circulation. It has been translated and distributed in all major languages including Japanese, Arabic, Portuguese, French, Italian, Russian, Chinese, German, Spanish and many more. There are seven editions in circulation. An enormous interest is evident in the subject matter. An average of about fifty e-mails per day are received from the ends of the Earth (that is about 1,500 per month).

Once the Web Site and the book are viewed, it will become evident that abundant, self-sustainable energy is available everywhere for the taking. This is natural energy which does not harm the environment or those using it. The proper Device for Collecting is all that's required.

The Good News is that the problem is solved and with assistance, an ultimate source of energy which is environmentally benign, abundant throughout the universe and inexpensive to capture, is there for the taking.

Thank You for your consideration

Donald L. Smith, CEO

MEM

Electrical Energy Generating System

Description and Function:

The Generation of Electrical Power requires the presence of electrons with various methods of stimulation, yielding magnetic and electrical impulses, collectively resulting in Electrical Energy (Power). In place of the mechanical - coils and magnet system, present in conventional electrical power generation, visible moving parts are replaced by resonate magnetic induction, using radio frequency. Transfer of energy by resonate induction is related to the ratio of the square of the cycles per second.

The Energy System, presented here, operates at millions of cycles per second verses the conventional 60 C.P.S. This tells us that it has a frequency advantage over conventional methods. This same advantage applies to the amount of electrical energy output. Therefore the Device is small in size and produces large amounts of Electrical Energy. The Electrons acquired, are from the surrounding Air and Earth Groundings, being the same source as in conventional methods. This is accomplished by magnetic resonate radio induction.

Applications:

This Electrical System adapts nicely to all Energy Requirements. It is a direct replacement for all existing Energy Systems. This includes such things as Manufacturing, Agricultural, Home Usage, Office Complexes, Shopping Centers, Rail Transportation, Automobiles, Electrical Power Grids, Municipalities, Subdivisions, and Remote Areas. Briefly, the only limiting factor is the imagination.

Economic Possibilities:

No Historical Reference Point exists for a comparison of the Possibilities of this System. One can see from the impacted applications listed above, that the magnitude exceeds any known invention, presently a part of the Human Experience.

Present and Future Plans:

The Energy System has been in the developmental stage during the past seven years. It is Patent Pending # 08/100,074 with the Patent Office. No prior art exists according to the Patent Office's response. The System is presently being introduced into the World Market.

Useful energy occurs as the result of imbalances in the ambient background energy, which is a transient phenomena. In the electrical field, it is a closed system subject to heat death, which severely limits it's utility. The flip side of the electron, produces magnetic waves which are an open system, not subject to heat death. These waves, being unrestricted, are the universal source of energy when unlimited resonate duplicates from this one source are available. Therefore, the key to unlimited energy, is Magnetic Resonance. In order to understand this, requires putting a stake through the Heart of Antique Physics. Non-linear and Open Systems are universally available in Magnetic Resonance Systems, Explosions of any sort [including Atomic Explosions] and Combustibles of any type. Mechanical equivalents would be levers, pulleys and hydraulics. A highly obvious example is the Piano where the Key impacts the one note giving one sound level, which resonates with it's two side keys providing a much higher sound level. Magnetic Resonance Energy clearly amplifies itself, demonstrating more energy out, than in.

Ohmic resistance does not apply to Magnetic Resonance which travels unrestricted for great distances, therefore multitudes of electrons are disturbed, and their back-spin translates magnetic into usable electric energy. The right angle component which the magnetic flux provides, translates into useful electrical energy. Taken at right angles, the Magnetic Dipole provides an unlimited source of electrical energy. The writer is recognized world-wide for his knowledge and experience. See his Web Site at altenergy-pro.com .

Gravity is a function of spin phenomenon as observed in gravity separation of liquids. When spun, milk and cream separate. Therefore, relative specific gravity is function of mass versus spin. Magnetics and gravity are both spin related. In part, a top levitates when spun. Therefore, spinning magnetic fields are a functional motor source as in flying saucers.

ABSTRACT: Technology of New Energy:

Developments in the understanding of Electricity, along with Materials which were not previously available, allows the construction of Devices which collect energy in large quantities, from the Earth's Ambient Electrical Background. This Energy is naturally occurring, environmentally benign and is available everywhere. It is available wherever and whenever it is required. New Devices use Resonate Magnetic Waves which replicate upon spinning the locally present electrons, providing multiple duplicate copies of the Energy Present. Each electron when spun yields both magnetic and electric waves in equal proportion. The electrical component is a closed system limited by Ohms Law. The magnetic component is an open system not limited and it replicates multiple copies of the energy present.

Special materials and recent developments allow the magnetic energy to reproduce, through resonance, unlimited duplicate copies acquired from the ambient background. These Devices harvest the energy that has been, and is always present universally. Conventional methods consist of coils and magnets systems. Upon moving past each other, the magnetic flux field disturbs electrons which yield electricity, which is collected by the coils system. This is accomplished electronically with the new technology, without any moving parts and the energy is multiplied such that the Device becomes self-sustaining once it is started. This Technology, already presented Worldwide, will be shown at the Conference.

Dr. Smith
www.altenergy-pro.com
e-mail donsml@earthlink.net

"Putting a stake through the Heart" and thus removing the mental block created by antique physics is required. Conditions wherein this becomes necessary are non-linearity, resonance and explosions of any sort. Combustibles of any sort such gasoline and atomic explosions are good examples wherein more energy out than in, is obvious. You can add to that the non-linearity found in pulleys, hydraulics, steam power and suchlike. Magnetic resonance is a highly obvious source for multiplying energy output. The sound system present in the piano, demonstrates this very clearly. Energy amplification clearly present in the above, demonstrates the silliness attested to by many Physicists.

Ohmic resistance does not apply to magnetic resonance which travels unrestricted for great distances, therefore multitudes of electrons are disturbed, and their back-spin converts from magnetic energy to usable electric energy. These same electrons have been around from the beginning of time and they are undiminished and will remain so until the end of time.

ELECTRICAL ENERGY SYSTEMS PREFACE

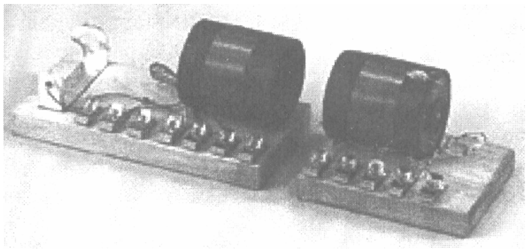
Useful Electrical Energy is obtained directly from electron spin induced by incoming magnetic waves, or indirectly through mechanical exchange as in dynamo type devices. Simply put, electron spin converts from magnetic to electrical energy and vice versa. Nature provides grand scale magnetic wave induction throughout the universe, for free. In Electrical Systems, movement is at right angles to the direction of current movement. This explains the rotary movement of the Earth and other related Systems. The rate of Spin for the Earth is known as well as the mass (5.98 x 10^{24} Kg - "Physics for Scientist and Engineers", by Raymond A. Serway, Saunders College Publishing, 2nd Ed. page 288, Table 14.2), therefore the amount of incoming Electrical Energy which produces this action can be calculated.

It can be seen quite easily, that the incoming magnetic wave energy is Vast and Continuous. As an accretion mass, the Earth is an Energy Sink, getting it's energy from elsewhere, being Cosmic, Galactic and Solar. Conversion of incoming magnetic waves into electrical energy provides an unending, inexpensive and environmentally friendly source available to all. Cosmic and Galactic Energy is available twenty four hours per day. Large amounts of this Energy accumulates in the Earth's radiation belts. This Giant Energy Storage, when properly understood, provides a major source of free unending electrical energy. Each of My Inventions plugs into this vast energy source.

A perverse, Intentional Ignorance on the part of the Establishment, prevents recognition of the importance of the Energy Systems shown here. Any new system which is favorable towards the masses, is considered as disruptive, and therefore not allowed. Those who have the (Gold) Energy Rule (Golden rule) Mandated Destruction of all Humanity is not a consideration.

This Presenter will remove some of the Fog placed with the intention of preventing the recognition of this unending, environmentally clean, electrical energy Source, which is present everywhere throughout the Universe. The Cost of Harvesting and Using this Free Energy is a function of Human Stupidity.

RESONANCE CIRCUITS DEMO



Used to demonstrate electromagnetic radiation between two UC circuits - one a transmitter and the other a receiver. When the 1.5 volt power transmitter is pulsed, the radiated signal is picked up by the remote receiver circuit which then lights up a 70 volt neon lamp.

With this apparatus, the student quickly understands some basic principles governing wireless communication, broadcasting, etc.

Kit: #10-416 $49.95

ULTIMATE ENERGY SOURCES

A human is a speck of dust on Earth, the Solar System is a speck of dust in the Galaxy and in turn, the Galaxy is a speck of dust in the Universe (Cosmos). All of these respectively represent vast ambient energy reservoirs. Awareness of the Sun, opens doors into other energy sources. Electromagnetic Energy which is present everywhere throughout the Universe, is accessed by catalytic activity, directly as in Solar Cells or indirectly as by mechanical means. Resonate, Magnetic Waves (Faraday's "Action at a Distance") allow Energy Activation Transfer to remote points of usage. The method of capture and use of this Energy is optional, and therefore it's cost is a function of Human Stupidity (Free-Energy).

Direct access is more desirable, and technology transfer from Solar Cell-type Devices provides the Catalyst. Enormously high Ambient Energy Levels are not detected by instruments that use the Ambient Background as a Reference Plane. A spoonful of water lifted from the Ocean does not define the Ocean. Incoming magnetic waves are reflected, Deflected or absorbed. Deflected Magnetic Waves spin electrons sideways producing useful Electrical Energy. Absorbed Wave Energy produces heat, therefore a hot interior for the Earth. In Electrical Systems physical movement is in the direction of current flow, frictional drag from inflow current defines gravity. Accretion masses resulting from Energy Sinks, provide all solid entities with their respective gravitational effect.

Increasing the tolerance level for Intellectual Awakening opens Doors of Reality. These doors blink into, and out of existence, and upon recognition, benefit Mankind. Opening some of these Doors, which at the present time are seen through a deep fog, is our purpose. Exploring Unrecognized Energy Sources, which are a Part of the Ambient Background, is another goal. Our Available Instruments do not use reference planes which allow recognition of this energy, as we shall see, vast Energy Sources that totally surround us are available through Technology Transfer. They are inexpensive (Free), fully self-renewable and environmentally benign.

Incoming Magnetic Wave Energy with Faraday's "action at a distance" will be looked at closely. Particle Physics will be left for the Astrophysics. Excited Electrons at point "A" the Sun (including the Galaxy and Cosmos) do not travel to point "B" the Earth, however a corresponding action occurs at point "B". The Electrons being disturbed at the Central Power Plant, in the same manner excite the Electrons at Your House, upon switching into an Earth grounding (known as "flipping the switch"). Correspondingly, there are Four Major Power Sources providing enormous amounts of Ambient Background Magnetic Wave Energy. They are The Cosmic, Galactic, Solar and Earth's Ambient Electromagnetic Backgrounds. The Earth's Electromagnetic Field comes from reflection, deflection and absorption as a result of action at a distance from the above.

Prescription Physics mandates that the Earth's background is of little interest. When we have Considered the evidence herein, it will become obvious that Special Interest's effort at keeping the People ignorant has, until now, largely succeeded.

Information for the entire World is available regarding the Magnetic Flux Background of the Earth's Surface (United State's Geological Survey, Colorado, USA, Office). When examined and properly understood, these Maps yield important information regarding reflection, deflection and absorption of incoming Magnetic Waves, plus action at a distance. When properly understood, these Maps reveal a very large Ambient Electromagnetic Energy Source. This is the Part of the Earth's Energy System that relates to the Bird on the High Voltage Line. When deflected, magnetic flux from electrons changes to electrical flux, providing the Motor System that spins or rotates the Earth. Physical movement by electrical systems is from inflow current movement. What level of current movement is required to spin the Earth? The Earth's Mass is 5.98×10^{24}. From this Information, the Watts of Electricity Required may be calculated! Absorbed microwave flux energy heats from the inside out, therefore a hot interior of the Earth results. Water is strongly diamagnetic, and on windless days, ocean waves provide visible Proof of the overhead incoming magnetic flux. From the information above, the Earth's weight and rate of spin allows the calculation of the amount of incoming ambient background energy required. As You can see, it is not inconsequential as Prescription Physics mandates.

Astrophysicist are concerned with charged particles that whiz by, once every one hundred years, rather than Wave Phenomenon associated with action at a distance. This highly Active Wave Energy translates into Electrical Energy at point "B". The Galaxy is alive With Energy which is billions of times greater than that of the Sun. Visible Light is a very tiny part of the Electromagnetic Energy Spectrum. Frequencies present in the Galaxy and Cosmos allow Radio Telescope photographs of their existence and magnitude. One such 408 MHz photograph of the Electromagnetic Energy Spectrum shows that the Earth is a tiny speck of dust in this Enormous Ocean of Energy, and can be seen near the left end of the Central High Energy Area.

This Energy extends in all directions. Accretion and formation of Planets, Suns and Galaxies are results of energy sinks and variable sized black holes. Mass retains heat, and is cooked from the inside out by the microwave background energy provided by the Universe. Flux movement into energy sinks, provides the frictional force know as gravity. Spinning mass in the presence of incoming flux amplifies the gravitational effect.

At present, only Solar Energy is recognized. It is inconsistent, flaky and a very small Part of the Magnetic Wave Energy Present. Technology Transfer from Solar Power provides uncomplicated and inexpensive, direct access to the Other Greater Energy Sources. All Electromagnetic Energy harvesting methods include a Catalyst, a Collector and a Pump. Catalysts include sensitization through doping with certain elements, air and earth groundings. Collectors include temporary storage as in Capacitors, Coils and Transformers. The Pump System includes induced movement onward to the point of use. Conventional rotating coils and magnet systems activate electrons present, such that action at a distance can occur, therefore it is an energy activation pump. In Direct Access Systems such as Solar Cells, the same occurs without mechanical action. Direct access occurs when Magnetic Waves impact a catalyst, spinning the local electrons sideways, producing useful electrical energy.

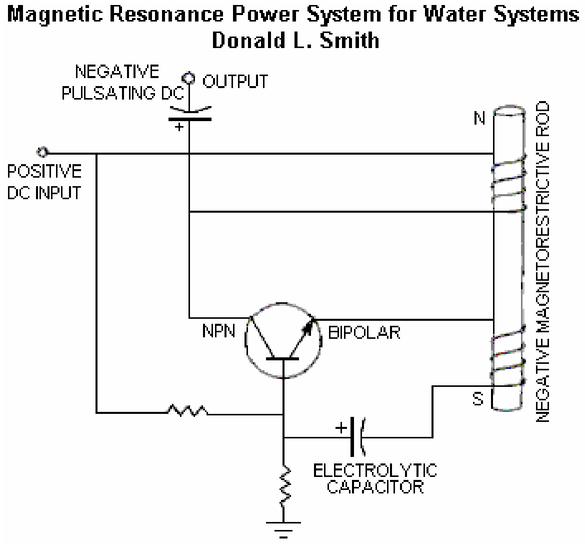
Indirect acquisition of electrical energy by mechanical means is wasteful, troublesome, expensive and degrades the environment. The dynamo is a combination collector and pump of energy which is collected from the Earth's Ambient Energy Background. Generators do not. make electricity, they collect it from the Ambient Background and forward it, as in Faraday's "action at a distance". Energy Conservation Laws relating to these systems, relate to gray areas, and when understood, are excluded because of the existence of External forces, open and non-linear systems as per Einstein. The Knowledge Base just viewed, provides a Direct Understanding of the Requirements for Harvesting of unending, fully renewable, environmentally benign Sources of Electrical Energy.

Magnetic Resonance Power System
Suggestions for Construction

This is the Basic Sonar Power System which permits submarines to see approximately 50 miles distance. What is not commonly known is that it works better at higher frequencies in the Gigahertz range. Any Device that can radiate 50 miles plus, is producing an enormous electromagnetic disturbance from a small input into a rod of magnetostrictive material. Disturbing the Earth's Ambient Background plus the strong dipole being produced, turns the magnetostrictive rod into a combination of a receiving antenna and a vastly superior output transformer.

The Drawing is only the Key Unit. A power input module and an output inverter circuit (diode bridge plus output transformer) are also required. The metal core and the wire size of the output transformer, plus adjusting the Earth Grounding of the Load, will determine the Amperage.

The Ideal rod material is Terfenol-D (check the internet). However a 1.5" diameter 10" long rod, costs over $5,000 each. Less expensive alternatives are obvious. When constructing, use PVC tubing with removable caps. Wind the coils on it and insert the experimental rod. Use only magnetostrictive material. When you get it right, you will have exactly what the Doctor ordered:



Magnetostriction oscillators work by magnetic resonance in a rod of magnetostriction material. This rod serves two purposes: It vibrates at the frequency of resonance oscillation, and it becomes the feedback transformer. Frequency is determined by items 4, 5, 6 and 8. The diameter, length and volume of the rod and output windings, determines the output. Item 2 provides feedback into the system. The negative magnetic character of item 8 plus the windings 2, in reaction to the magnetic flux field provided by 9, increases (amplifies or magnifies) the output. Magnetic permeability is the counterpart of negative resistance. Resonating with negative magnetic resistance, it pumps energy from the Earth's ambient background. Magnetic permeability is the ratio of flux density (Earth's B field) to the magnetizing force (H) in oersteds.

Magnetostrictive materials are piezoelectric in character, and have a very high resistance to electrical current flow. Examples are:

1. Permealloy Negative Magnetic Permeability	> 80,000
2. Sendust Negative Magnetic Permeability	30,000 -120,000
3. Metglas Negative Magnetic Permeability	> 200,000
4. Iron with (34%) Cobalt Magnetic Permeability	13,000
5. New Technology Magnetic Permeability	> 1,000,000

ELECTRICAL ENERGY SYSTEMS METHODS

1. **DIRECT -** Faraday's "Action at a Distance" incoming magnetic wave conversion to useful electrical energy. This includes Cosmic, Galactic, Solar and Magnets. Technology Transfer is from Solar Cell Technology.

2. **INDIRECT -** Electron Stimulation-Induced Electron Spin Systems, Electron Avalanche Pumping Systems

   Primitive, Indirect Conversion from another form of energy. Coils and Magnet as in Dynamo Systems (Closed Systems). Chemical Systems, Atomic, Pons & Fleischman and etc.

   Advanced, Direct Conversion, Magnetic Wave (Open Systems).
   Ambient Sources
   Air Core Coil Systems
   Gaseous Tube Systems,
   Solid State Marx Generator Avalanche Type Systems.
   Leyden Bottle Capacitor Types inserted in Lakes and other.
   Magnet Systems
   Electron Beam Antenna Systems

3. **TRANSFER MECHANISMS**

   Solids - as in metal conductors

   Gaseous as in radio wave transmission, a form of ionization.

   Sensitizing of Systems by use of Trace Doping with Radioactive elements, includes metal surfaces.

   Open Systems, non-linear with external forces. Albert Einstein in a direct quote from his biography states that these are excluded from the conservation of energy laws.

   Closed Systems Maxwellian Type Systems. Mathematics are predictable requiring deductive reasoning. Ohm's Law is King, and Establishment Intellectuals being comfortable with this, brand all else as a violation of the Laws of Nature by obtaining something for nothing. This is Dishonesty grand mal.

AMBIENT ENERGY SOURCES

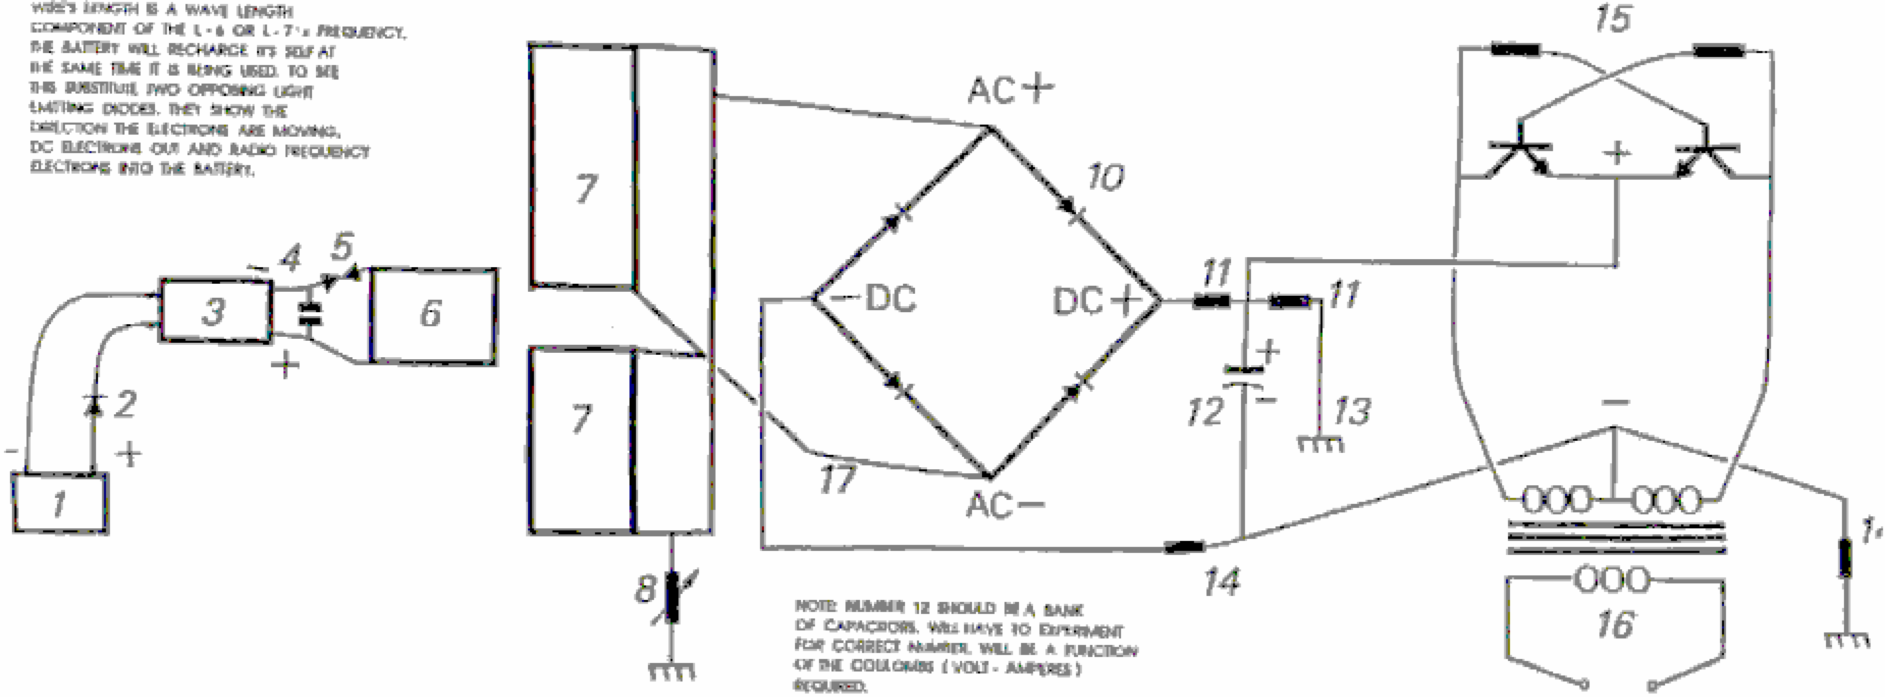
Radiation System	*Diffusion Method*	*Magnetic Wave Energy*
1. Cosmic	**Reflection, Deflection and Absorption**	**Ultraviolet**
2. Galactic	**Reflection, Deflection and Absorption**	**Infrared**
3. Solar	**Reflection, Deflection and Absorption**	**Visible Light**
4. Earth	**Reflection, Deflection, Absorption,** **Faraday's "Action at a Distance"** **also, a Composite of all of the above**	**Earth's Electrical**

A deep fog pervades the entire Scientific Community with regards to the Significance of the Above Energy Sources. Magnetic Waves convert directly into Electrical Waves (useful electricity). Two sides of the electromagnetic system are always present and never separate. Local electron spin provides (action at a distance) the flip side of the incoming magnetic wave energy.

Enormous amounts of incoming magnetic wave energy becomes a part of the Ambient Background, and as such, cannot be measured directly. Reconstruction from indirect information, allows us to establish the actual energy levels which are present. Instruments provided by the Scientific Community measure only point "A" to "B", and when both are ambient, no potential energy is shown. This is the "bird sitting on the million volt power line and sensing nothing" approach. The Earth's actual ambient background has as it's Energy level multi-billions of Volts, which are conveniently and obliviously ignored by the scientific community. When properly understood, this enormous, never-ending source of environmentally-friendly energy becomes available.

ELECTRICAL ENERGY GENERATING SYSTEM

Patent Pending 08 / 100,074



NOTE: IF THE PLUG CONNECTOR (2) WIRE'S LENGTH IS A WAVE LENGTH COMPONENT OF THE L-6 OR L-7's FREQUENCY, THE BATTERY WILL RECHARGE IT'S SELF AT THE SAME TIME IT IS BEING USED. TO SEE THIS SUBSTITUE TWO OPPOSING LIGHT EMITTING DIODES. THEY SHOW THE DIRECTION THE ELECTRONS ARE MOVING, DC ELECTRONS OUT AND RADIO FREQUENCY ELECTRONS INTO THE BATTERY.

NOTE: NUMBER 12 SHOULD BE A BANK OF CAPACITORS. WILL HAVE TO EXPERIMENT FOR CORRECT NUMBER. WILL BE A FUNCTION OF THE COULOMBS (VOLT - AMPERES) REQUIRED.

1. Gelcel, 6 or 12 Volt,
2. Diode, Pass. use a Varactor,
3. High Voltage Module, Constituting the L-1 and L-2 Coils.
4. Capacitor, TDK 10.9 Pf., 30 KV,
5. Spark Gap, Small Engine Spark Plug, Gap = .0025 In.
6. Induction Transfer Coil L-3.
7. Induction Receiving Coil L-4.
8. Voltage Control Shunt.
9. Frequency Adjustor, prevents derating by Diode Bridge
10. Diode Bridge, 200 Nanosecond, R.F., > 100 KV .
11. Voltage Divider Circuit, corrects voltage for next stage.
12. Capacitor, electrolytic, smooths out DC + ripple effect.
13. Earth Ground.
14. Voltage Divider Curcit, corrects voltage for Transformer
15. Inverter Circuit, DC + in and 60 CPS to Transformer
16. Output from Transformer to Load (Work).
17. Center Tap

Electrical Energy System

Don L. Smith, Energy Consultant

At a meeting between J.P. Morgan, Edison and Tesla, Tesla proposed an Electrical Energy System which could he connected into directly, without using a meter. Tesla's Idea of "Free Energy" was not compatible with their thinking. Courtesy of Morgan and Edison, from that day foreword, a complete and total bastardization of the Idea has been in progress. Agents for Morgan and Friends include the U.S. Patent Office and Academia. Academia's bad habit of incestuous quoting of each other, eliminates them as a possibility in cleaning up the mess. This selective ignorance, permeates throughout the study of electricity.

Many people, otherwise known as "intellectuals", have a total blackout and become jabbering idiots when "free-energy" is mentioned. The term has been amended to say, "something which was never there is being harvested and that this violates the laws of physics". For the selectively ignorant, this seems the way to run. Those who choose Morgan's drum beat, have severely limited the possibilities built into electricity.

This paper will be an exercise in creative understanding, in placing updated knowledge at your disposal. Whether it becomes a useful tool or is selectively ignored is your choice.

Electrons are defined as being the practical source of electrical and magnetic energy. The electron as a particle, was postulated by professor J. Thompson in early 1900's. It is now universally accepted that the electron exists and that it is the source of electricity. When the electron is agitated it produces magnetic and negative electrical energy. Physics as it exists today, cannot explain why the electron remains intact and is not diminished by the energy it releases. This is a part of the built-in ignorance provided by the Morgan and Edison Camp.

One volts worth of electrons, when cycled, yields one volts worth of electricity. This can be repeated continuously forever and it never deplete or diminishes the electrons in question. They simply return to their air and/or earth source, waiting to do the whole thing again and again. Therefore, electrical energy is available, anywhere and everywhere humans go. People who intercede for profit, set the cost of electrical energy. Otherwise, all electrical energy is free, Morgan and Edison be damned.

Improving upon Professor Thompson's postulation, other obvious characteristics can be seen to further define the electron. It has both magnetic and electrical emanations resulting from a right-hand and left-hand spin. Since magnetism and amperage come as one package, this suggest, that electrons in their natural non-ionic state, exist as doublets. When pushed apart by agitation one spins and supplies electricity and the other spins and provides magnetic (amperage) energy. When they reunite, we have Volts x Amperage = Watts. This Idea, until now, has been totally absent from the knowledge base.

The number of times that an electron is cycled, sets the collective energy potential present. The electrical equivalent of $E = mC^2$ is $E = (\text{Volts x Amperes}) \text{ x } (\text{Cycles Per Second})^2$. Those who choose, are now free to head for the bushes and make their usual contribution to humanity.

Prior to Tesla, there was a large group of people in Europe, who were building resonant coil systems for medical use. Amperage was dangerous in their coil systems. The Tesla Coil is only the Voltage half of their coil system, as will be demonstrated.

A short list of those (from 1860 onwards) active in resonate high frequency coil systems include; the Curies, Roentgen, Ruhmkoff, Oudin, Hertz, Levassor, Dumont, D'Arsonval and many others.

Peugeot, Panhard-Levassor, Bollee, Renault and others had successful electric automobiles in production using A C. motors. Various electrically-powered airships, including the Dirigible "France" were in service.

D'Arsonval, Professor of Experimental Medicine at the College of France, invented the electrocardiograph, oscilloscope, amp and volt meters, thermography and numerous other medical applications of high frequency electricity. As early as 1860, he was building high frequency coil systems, which he used in his experimental work. There is a strong connection between the work of Tesla and the people mentioned above.

Electric vehicles of all sorts, dominated until the 1920s, when the electric starter motor made the internal combustion engine practical. Prior to that, upon cranking, it frequently would break the owner's arm. At that point the use of batteries as a source of power was replaced by oil.

The establishment's carpet has some rather large lumps under it. Coulomb's and Newton's inverse square law is politely ignored and it's opposite is allowed to have only the most abstract status. Without opposites we have no definition.

The source value of a remote flux reading, requires the squaring of the distance, times the remote reading, to obtain the original value. The opposite of this, being the derivations relate to Energy equals Mass times the Velocity constant squared. The electrical equivalent, being Energy equal capacitance times voltage squared and Energy equals induction times amperes squared. Flux lines increase as the law of squares and then activate electron energy which was not previously a part of the sum. The cumulative capacitance and inductance increase as the outer ends of a Tesla coil are approached, and this results in output energy being greater than the input energy present. This Energy is real. It can be safely measured by magnetic flux methods and electrostatic voltmeters, based on the inverse square law

As seen above, flux lines result both from induction-henrys-amperage and capacitance-coulombs-volts, and define electrical energy. The non-linearity of this system does not obey Ohm's law, which is replaced with impedance and reactance for alternating current systems. Impedance is the sum of the system's resistance to AC current flow, and this becomes zero at resonance. In resonant induction systems, a cycles-per-second increase, invokes a second round for the law of squares.

The degree to which flux lines are present, disturbs an equal amount of electrons, upsetting the ambient background energy, resulting in useful electrical energy being obtained. The frequency at which the disturbance occurs, increases the useful energy available, and it obeys the law of squares. Two square-law components, *flux density* and *frequency* are involved. Enter resonance which cancels the resistive effect.

Only the electrical energy which is either above or below the ambient level is useful. For the Central U.S. going east to west, ambient as approximated by electro-static voltmeters and flux methods is 200,000 volts on a solar-quiet day. At night time, the ambient energy level drops to about one half of the daytime value. On a solar-active day, it may reach more than five times that of a solar-quiet day. Ambient background energy at the polar regions, is approximately 500,000 volts on a solar-quiet day. The background energy varies as it relates to the North-South component and the East-West continuum.

This leaves us with an interesting problem. Electrons, when disturbed, first produce magnetic flux and then produce electrical flux when they spin back to their normal position. Therefore any electron movement produces above ambient energy, being over unity.

ELECTRICAL ENERGY WITH ASSOCIATED PHENOMENA

1. Current-amperes results from the unequal distribution of negativity (electrons).

2. Electron spin causes electrical current and magnetic lines of force.

3. Magnetic imbalance causes the gravitational effect. This is evidenced in electric motors by magneto-gravitational displacement of mess, which causes the motor to rotate.

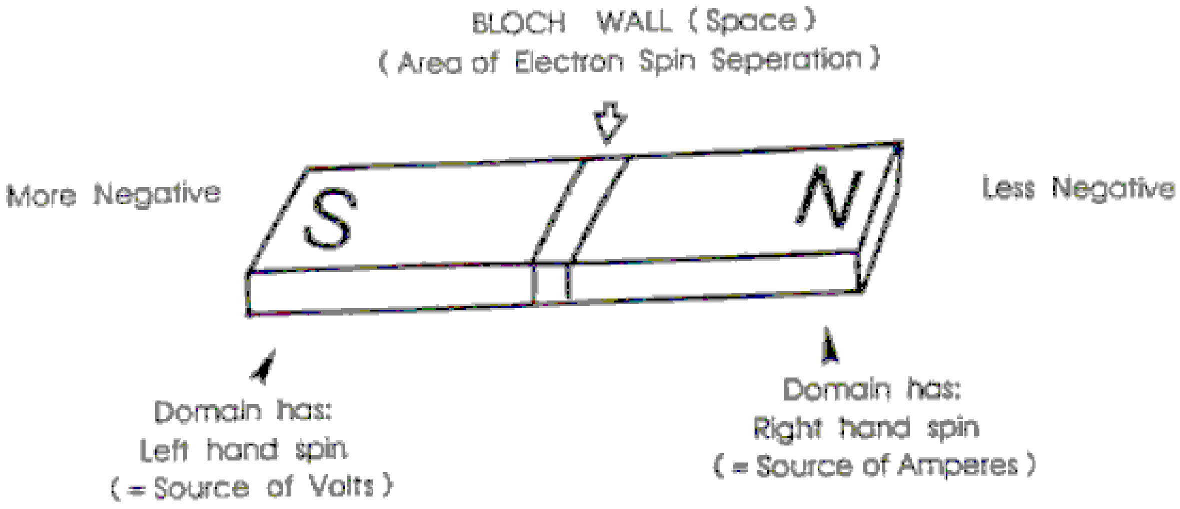
Derivation of Magnetic and Electrical Power

Analogous Relationships:

1. Potential Power is present in a bar magnet as shown:

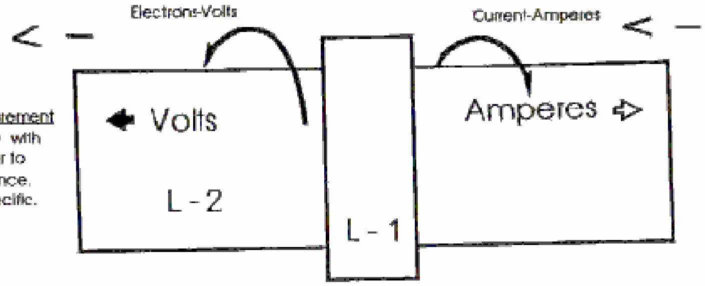


BLOCH WALL (Space)
(Area of Electron Spin Seperation)
More Negative
S
N
Less Negative
Domain has:
Left hand spin
(= Source of Volts)
Domain has:
Right hand spin
(= Source of Amperes)

2. The Source of these Electrons being from the Solar Plasma, are non-ionic and occupy all Free Space. They are commonly obtained from Earth and Air Groundings. They exist in Doublet Pairs, one being more negative than the other. The more negative one has a Left Hand Spin. The less negative one has a Right Hand Spin.

3. Resonate Electrical Coil Systems (Tesla) are Analogous to the System observed in the Bar Magnet (above). The Bloch Wall Area is Located at the base of the L-2 Coil. The Left Spin portion of the coil (Voltage Only) Coil predominates. The Right hand Spin portion of the coil (Magnetic-Amperage) is mostly absent.

Tesla Coil Geometry *



Correct Method of Measurement
Use the inverse square law with an Electrostatic Volt Meter to measure from a safe distance, they are frequency nonspecific.

Correct Method of Measurement
Use the inverse square law with Hal-Effect devices to measure from a safe distance, they are normally frequency nonspecific. The magnetic field they measure converts directly to Amperage

Volts dominate if the L-1 Coil is far right
Volts and Amperes about equal if L-1 Coil centered

This End Has Greater Voltage
Distributive Capacitance at Maximum
Capacitance-Coulombs-Voltage
Voltage has Electrons spinning to Left

This End Has Greater Amperage
Distributive Inductance at Maximum
Induction-Henrys-Amperage
Amperage has Electrons spinning to Right

Volts represent the more negative and Amperes the less negative. Therefore the electrical charge of more negative must seek the less negative to regain ambient.

Induced Electrical Energy System

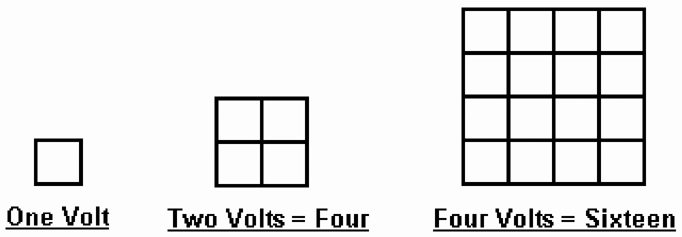
Collection and transfer of energy requires temporary storage, which occurs as capacitors and coils of a resonant circuit are cycled, on and off. The frequency at which the capacitors and coils are pumped, determines the amount of electrical energy that moves onward.

The amount of Energy transferred relates directly to the density of lines of flux present. The Kinetic Energy Formula is helpful in establishing the amount of energy present. This formula squares the velocity times mass. In the case of electrical energy, the intensity of voltage and amperes multiplied by the cycles per second, replace the velocity component.

Note that the "acceleration" of the Voltage "E" and Amperage "I", which increase as non-linear components, then obeys the Law of Squares.

Each unit of increase, causes a squaring of the flux lines present. The amount of energy transfer caused by this increase in flux lines is demonstrated below.

Increase in Flux Lines Present Symbolized



In resonant air-core coil energy transfer, the increase in flux lines present disturbs more electrons than previously, resulting in over-unity energy being present and available.

Energy stored, times the cycles per second, represents the energy being pumped by the system. Capacitors and inductors store electrons temporarily.

Capacitor formula: **W = 0.5 x C x E x Cycles per second** where:

W = energy in Joules (Watt Seconds)
C = capacitance in farads
E = applied potential in volts squared.

Inductor (Coil) formula: **W = 0.5 x L x I x Cycles per second** where:

W = energy in Joules (Watt Seconds)
L = inductance in henrys
I = current in amperes squared

Both one henry, and one farad, equal one volt. The higher the cycles per second, including the squaring of the flux lines, cause a large increase in the amount of energy being produced.

The above combined with a resonant energy induction system (where all electrons are moving in the same direction at the same time), make the next move into over-unity practical.

The dampening process of conventional electrical power generation, has all the available electrons bouncing randomly, mostly cancelling out each other. In that System, the useful energy available is a very small percentage of the energy which is present.

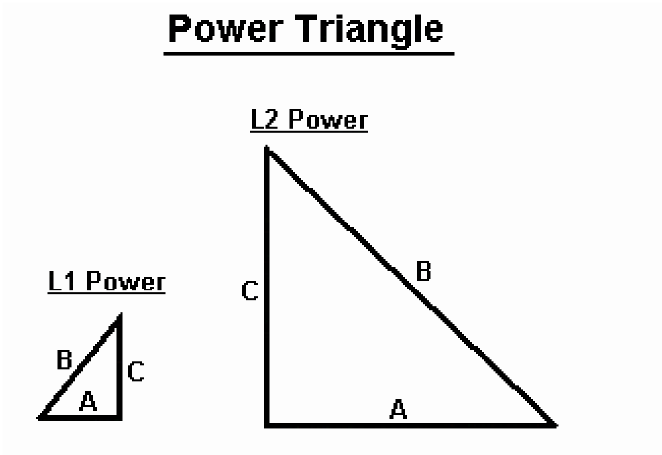
In the resonant induction system, a very high percentage of the energy present is useful. At resonance, (ohms-impedance-Z) becomes zero and all of the energy present is not degraded and becomes available to do useful work. "Ohms" is load or wasted energy, and "amperes" is the rate of that wasting of energy.

Using the previous information, if we now apply it to an air-core coil, resonant transformer energy system. L-1 and L-2 coils are now present. L-1 has a smaller number of turns and is several times the diameter of L-2. Input from a 12 volt high-voltage laser driver source, produces 8,000 volts with a low level of wasted energy, pushing amperage into, say, 4 turns of coil L-1. Each turn of the L-1 coil then acquires 2,000 volts of resonant potential. Consequently, each turn of L-2 is then exposed to the electric flux of 2,000 volts. Each turn at the bottom end of L-2 acquires 2,000 volts. The flux lines are squared and are additive as the voltage and amperage progresses towards the top end of L-2's large number of turns.

A huge number of additional flux lines which were not previously present become present at the top end of the L-2 coil. These flux lines excite the nearby electrons in it's earth and air and groundings. This high level of excitement above the ambient, causes a large number of electrons which were not previously a part of the energy present, to become available for use. At this point over-unity is present in large amounts.

The "bubble gum between the ears" response to this is: "this must be lots of volts but no amperes". Please recall that amperage is wasted energy, and that until that wasting occurs, there are no amperes. A good way to demonstrate this, would be to let the bubble gum crowd put their hands on the high-voltage end of the device while standing on wet ground (a people zapper). **Note: don't do this.**

This over-unity device produces energy at radio frequencies which range into the megahertz band. This allows the device to be small in size, and yet produce large amounts of energy. A megawatt-sized unit will sit comfortably on a breakfast table. This energy is changed to Direct Current and then switched to produce the desired working frequency AC.



A: Volts x Amperes (the Available Power)

B: Volts x Ampres x Time (the Used Power)

C: Volts x Amperes x Recative (the Resinant Power)

1. Random movement of electrons in "A" and "B", mostly cancel each other out. This dampening, or wasteful concept of energy, is a source of much pleasure for the establishment.

2. "C" (Volt, Amperes, Reactive "V.A.R."), is the situation where all of the electrons move in the same direction at the same time. This results in near-unity energy output by resonant induction transfer.

3. Resonant induction transfer from one isolated power system, allows other resonant induction systems to duplicate the original source, which in no way diminishes the original source. Air-core coils (isolation-transformers) confirm this when they are a part of one of these functioning systems. A less perfect illustration would be the fact that the number of radio sets tuned to a particular radio transmission, does not alter the power required at the radio transmitter.

4. Resonant induction transfer, disturbs a large number of adjacent electrons which were not a part of the original input power source. The pulsating-pumping effect then draws in the newly available additional electrons into the on-going energy generation system. A near unity energy system of resonant air-core coils and the extra acquired electron-energy source constitute an over-unity system.

Electrical Power Generation / Points of Reference

Useful Electrical Power is Generated when Electrons from Earth and Air Groundings are disturbed by the movement of coils and magnets with reference to each other. The resulting electrical and magnetic energy is then changed to joules [watt-seconds: Volts x Amps x Seconds]. Each forward electron movement results in a magnetic impulse and each return movement causes an electrical impulse. The composite of the electrical energy impulses from these electrons yields useful energy [Power].

Let the above electron movement be represented by a room full of ping pong balls bouncing randomly. Most of the energy present cancels out by random impacts. This is the Classic Under-Unity approach to Electrical Power Generation, sanctioned by the Establishment.

In contrast to that, in the Electrical Energy Generation System presented here, the resonant Electrons are all moving in the same direction at the same time. This allows Near-Unity Electrical Power to Develop. This is the room-temperature equivalent of super conductivity.

The Energy System presented here, consists of a properly-adjusted and functional resonant air-core coil tank. The magnetic energy is stored in the coil system and the Electrical Energy is stored in capacitors. From Maxwell and others, we know that electrical-related energy has an equal amount of magnetic energy associated with it.

"The formula which establishes the Useful Energy of the System":

Joules = 0.5 x **C** x **V** squared x **C.P.S.** squared
units:
Joules (Volts x Amps x Seconds) Watt Seconds

C = Capacitance in microfarads
V = Potential in Volts
C.P.S. = Cycles per second

The transfer of Electrical Power by Resonant Induction is a direct function of the squaring of the cycles per second. For example, square 60 C.P.S. and then square the radio frequency C.P.S.s of the System here presented. Obviously, One Million Cycles per Second transfers more energy than Sixty Cycles per second. The Sanctioned Method of Electrical Power Generation uses the 60 C.P.S. Method. Using 60 C.P.S. and the random scattering of the Electrons System, assures the Establishment of it's desired Under-Unity Goal.

This random bouncing of the Electrons is the Ohms of Ohm's Law and is used to establish the rate of dissipation and/or Load [Work].

In the Resonant Tank Induction Energy Transfer System presented here, Impedance [system resistance] replaces the conventional ohm's usage. At Resonance, impedance becomes zero and the full force and effect of the Energy Transfer occurs. This is superconducting conditions at room temperature. At radio frequency the Electrons do not pass through the conductor as they do at lower frequencies. Instead, these Electrons encircle the conductor and are free of the conductor's resistance.

Let the Establishments Power Generation System be called 'A" and the System presented here be called "B".

With "A": Given 60 C.P.S. at 120 Volts using a 10 microfarad Capacitor:

Joules = [0.5 x 0.000010 x 120 squared] x C.P.S.s squared

(120 x 120 = 14,400)
[0.000010 x 14,400 = 0.144]
[0.144 x 0.5 = .072]
(0.072 x 3,600 = **259.2**]

Using the Inventor's Resonant Induction System, the Electrical Power available would then be 259.2 Joules [Watt-Seconds]. Using the Establishment's method only permits less than 10 Watt-Seconds of Useful Electrical Energy.

"B". Given One Million Cycles per second at 100,000 Volts, using a 10 microfarad Capacitor.

Joules = [0.5 x 0.000010 x 100,000 squared] x C.P.S.s squared

(100,000 x 100,000 = 10,000,000,000)
[0.000010 x 10,000,000,000 = 100,000]
(100,000 x 0.5 = 50,000]
(50,000 x One Million squared = **50,000,000,000,000,000**)

The useful Electrical Energy available is greater than 50 Mega Watts. Since the Resonant Electrons are non-impacting, all of the Energy is available for direct usage.

Benefits of the Inventor's System

1. Induction Energy transfer is enhanced by the squaring of the cycles per second produced by the System.

2. Induction Energy transfer is enhanced by the squaring the input voltage and amperage.

3. The increase of the flux lines occurring from the above, disturbing more electrons, causes more electrical energy to become available.

4. Resonant Induction has all of the Electrons moving unimpeded, resulting in superconductor conditions at room temperature.

5. A smaller amount of energy is used to disturb a larger number of Electrons. Electrons not originally a part of the System then contribute their energy, resulting in a net gain in available usable power.

6. The physical size of the System [Device] is small. The Device described in "B" sits comfortable on a breakfast table.

7. A small energy source is used to start the device and that source remains fully charged at all times by the System.

The Evidence Against Under Unity

1. Use of Logarithmic Scales on electrical measurement instruments. Linear measurement works fine where Ohm's Law applies (direct current). In alternating current, ohms are replaced by impedance and the measurements become non-linear.

2. Infinite "Q" at resonance confirms that voltage and amperage is squared, as in the kinetic energy formula. See the formulas of this report.

3. Square waves are clipped infinite "Q"s.

4. Maxwell and others show that magnetic-inductance-amperage and electrical-capacitance-voltage are two sides of the same coin. Magnetic-inductance is directly equal to amperage. Both obey the Law of Squares, which has over-unity built in.

5. Magnetic and electrical flux are present in enormous amounts at the outer ends of an operating Tesla Coil.

6. Ignorance of how to measure and relate magnetic and electrical flux, is the chief weapon of the under-unity gaggle.

7. The Cumulative inductance and capacitance of the Tesla Coil grounds itself out, if not properly utilized. See this report for the temporary energy storage accessible, when properly managed.

8. The Patent Office refers devices related to over-unity to their metering group, which is a sure indication that they are aware and accept the logarithmic measuring devices. This is direct and absolute evidence that they accept the square law as it relates to kinetic energy. This also indicates they are aware that over-unity exists. Since their bureaucratic brain is improperly motivated they continue to badger inventors who are working in the over-unity arena. Their level of intellectual dishonesty is sanctioned by, and is a real part of doing business with, a government which prides itself in being a hooliganistic bureaucracy.

An Answer to America's Energy Deficit

Donald L. Smith

Energy Consultant

Energy, energy everywhere and not a Joule to Jounce. Conventional wisdom, when properly tuned will appreciate the nature of energy, as here presented. The basic unit of electricity (the electron) upon encountering a moving magnetic field (or wave) spins, giving off an electric impulse. When this impulse collapses, it spins back to it's natural position, giving off a magnetic impulse. Therefore, magnetic and electric are two sides of the same coin. When the magnetic side is pulsed, it yields electricity and conversely, pulsing of the electrical side yields a magnetic field. Moving one in relation to the other produces useful energy. When done consecutively, each cycle pushes (current) forward, while pulling electrons into the system... in much the same way as a water pump moves water. These electrons are obtained from Earth and air grounding.

The word "electric" comes from the Latin word electron "amber". When rubbed, amber develops an electrical charge, which can be transferred to a dissimilar substance. During the seventeenth and eighteenth centuries, a great deal of attention was centered on this attribute of amber. Amber was used to differentiate the non-metals. Carbon-related substances and other non-metals, when subjected to friction, give up negative electrical charges. On the other hand, metals when subjected to friction, simply conduct the charge. It is important to note that approximately 70% of the Earth's exposed crustal portions (surface) consist of silicone-related non-metals (electron donors) and become a direct source of electrical energy when properly agitated.

Useful electrical energy can be obtained by grounding into the Earth's non-metal crust and into it's atmosphere as a natural source of electrons. These electrons have accumulated from the solar plasma during the aging of the Earth for more than 4.5 billion years, at a rate exceeding 3.9 exajoules per year This indicates that the Earth's electrical field contains in excess of 17.6×10^{18} of cumulative exajoules of energy. One exajoule is the approximate energy equivalent of 125 million barrels of oil. The electrical energy in one display of lightning is approximately ten trillion joules. During each 24 hour period, the land portions of Earth's surface yields in excess of 200,000 emissions, which involves more than 2,000 quadrillion watts.

C.F. Gauss (1777-1855) and H.C. Oersted (1777-1851) were each separately trying to define the Earth's electrical field with all external influences removed. These external influences being solar-quiet periods and being remote from the land's surface. The air electricity background which they measured varies with latitude. Their European measurements correspond to approximately the latitude of Washington. D C. They were measuring magnetic field flux as an indicator of negative electron energy active and present. A related family of measurement are now presented. Units of measurement used to define flux fields include Gauss (one unit = 100,000 volts), Oersted (one unit = 50,000 volts), Tesla (one unit = 10,000 Gauss) and Gamma (one unit = 1/10,000 of a Gauss). Much confusion exists in electrical related publications about these units. As presented here they are correct with values taken from their original definitions.

The entire surface of the Earth has been surveyed by aerial magnetometer, in most cases using gamma or nano teslas. One gamma is the magnetic flux equivalent of 10 active volts of electricity. When the data is corrected for flight height it becomes obvious that there are numerous areas where the gamma readings exceed one trillion gammas. Lightning strikes from the ground up are in that energy range. With knowledge of these electron enriched areas, the quality of Earth grounding, becomes enhanced. The correction necessary for land surface data when acquired from aerial magnetometer maps (using Coulomb's law) requires that the remote distance be squared and then multiplied by the remote reading. As an example, if the remote reading is 1,600 gammas and the flight height being 1,000 feet. Take 1,000 x 1,000 = 1,000,000 x 1,600 gammas = 1.6 trillion gammas x 10 volts = 16 trillion volts equivalent for land surface data. Present day methodology requires mechanical energy in exchange for electrical energy. Once obtained, this energy is subject to Ohm's Law. Present Methodology obtains it's electrical energy from it's non-metal and air groundings.

This same energy can be obtained without the wasteful mechanical approach and at a much, much lower cost. Any required amount of electricity is available by resonant induction transfer from the

Earth's magnetic and electrical fields. The major difference is in the functioning of Ohm's Law in relation to resonant circuits. In the resonant induction system suggested here, system resistance (Z) becomes zero at resonance.

Therefore, Volts and Amperes are equal (V.A.R.) until work (load) is introduced.

Each cycling of this resonant induction system pulls in additional electrons from the Earth's electrical field, generating electrical energy in any required amount. In this system, a small amount of electrical energy is used to activate and pull a much larger amount of energy into the system.

This electrical advantage corresponds to the pulley and lever of the mechanical world. The electrical system presented here is extremely efficient. Using present methodology as a basis for comparison, with it's 60 cycles per second system. The resonant induction system, cycling at 60 million times per second produces one million times the energy which is produced by the present energy systems. A single small size unit of the resonant induction system has more usable electrical output than a major conventional unit. The radio frequency energy produced is easily changed to Direct Current, and then to the present 60 cycles per second system in preparation for commercial usage.

The Patent Pending on this system is #08/100,074, "Electrical Energy Generating System", dated
4 February, 1992.

Definitions: One **Joule** is one watt for one second
One **Watt** is one volt ampere
V.A.R. is Volt Amperes Reactive

IN ALTERNATING ELECTRICAL ENERGY SYSTEMS, ONLY THE POTENTIAL-IMPACT LEVEL REPLICATES IT'S SELF AT POINT "B". ELECTRONS DO NOT TRAVEL FROM POINT "A" TO POINT "B".

E.E.S. II, BACKGROUND INFORMATION & CONCEPT

With alternating electrical current, electrons do not move from point "A" to point "B" as commonly envisioned! Electrical potential (oscillating electrons) at point "A", results in harmonic electron activity at point "B", when the grounding switch (circuit) is closed. That is to say, point "B" supplies it's own electrons and mirrors the activity of point "A". Impulsing (turbulence) by magnetic induction causes electrons to be pulled into the system, which then oscillates. When the magnetic field collapses (becomes absent) the electrical potential returns to it's natural background level.

Several major flaws are present in the conventional 60 cycles per second method of electrical power generation and it's iron core transformer system. ***This system is handcuffed by the inverse relationship of volts to amperes.*** This represents a stodgy, inflexible inheritance, courtesy of Mr. T.A. Edison and his concept of electrical power generation.

Nikola Tesla stood, almost alone, against Edison and managed to prevail with his Alternating Current system. Without the alternating current system, electronic things in the modern sense would not exist.

This report will be concerned with some of the extensions and benefits of the alternating current electrical system. ***This study will limit it's scope to air core coil transformers at radio frequency and upwards. The electrical power produced by this method is inverted to Direct Current and then to Alternating Current as required for popular usage.*** There are several important advantages of this system over conventional power generation.

Start with two coils (separate-apart), one being a reactor coil (L-1) and a second coil (L-2), being the reactant coil. Magnetic field fluxing (off-on of the electrical source) causes inductive reactance of L-1 which replicates by induction in L-2. Pulsing of the magnetic field (from L-1) in the presence of L-2, generates electrical potential. For example, should the L-1 coil have ten turns, with an imposed AC. potential of 1,200 volts. This results in each turn of L-1 acquiring 120 volts of potential. This induced magnetic field, then replicates itself in each turn of the L-2 coil. The L-2 coil may have one or many hundreds of turns. Modern encapsulation techniques makes high frequency and high energy controllable.

Let's take another important step in this air-core transformer process. For purpose of discussion, let the value of inductive reactance at 60 cycles per second, equal one. Each time the frequency is doubled, the effectiveness of induction is squared. At about 20,000 Hz, ***when radio frequency is achieved, the electrons begin spinning free, outside of the inductor and they become increasingly free of the inverse relationship of volt-amperes.*** From this point on, they replicate by the inductive process as V.A.R.. *That is to say,* ***volts and amperes are equal, until resistance (work) is introduced. Therefore, additional, not previously available electrons become incorporated for a very large net gain in potential. This gain is real !***

The quality of the grounding system determines the effectiveness of this method of producing electricity. A handy reference to locate the negative grounding areas for power generation can be found in the Aeromagnetic Map Studies of the US Geological Survey. They provide an excellent method for locating the best sites for optimum negative grounding areas.

When this method is combined with the induction coil system, already described, it provides an electrical power generating system millions of times more efficient than any known conventional method.

This new system ("E.E.S. **II**") is uncomplicated, physically small and it is inexpensive to build. The technology required for it's construction already exists. Maintenance is near zero, as there are no moving parts. Once operating, this system could last forever.

Small mobile E.E.S. **II** units are already available as replacements for the batteries used in electric automobiles. Larger E.E.S. **II** units can be provided as a replacement source of power for hotels, office buildings, subdivisions, electric trains, manufacturing, heavy equipment, ships, and generally speaking, any present day application of electrical power.

Earth Electrical System II, Modular Units

The system consists of three separate modules. Reverse engineering is used in matching the modules to the desired usage.

HIGH VOLTAGE INDUCTION TRANSFORMER MODULE:

1. Preferably an off-the-shelf-unit similar to a TV flyback and/or automobile ignition type related coil (transformer).
2. Ratio of input to output may be from less than 1:100 to greater than 1:1,000 A voltage tripler may then be used.
3. A connection allowing the high voltage output to pass onward through the induction coil L-1 and then to it's grounding.

AN AIR CORE INDUCTION COIL TRANSFORMER MODULE:

1. There are two coils: the reactor coil L-1 and the reactant coil L-2. L-1 has a high voltage radio frequency capacitor between it and it's grounding.
2. Input into the L-1 inductor is divided by the number of turns in it. The magnetic flux field provided from each turn of L-1 replicates itself as an electrical potential in each turn of L-2.
3. L-2 may have one turn or many hundreds of turns. The net gain depends upon the number of turns in L-2. Output from L-2 is in V.A.R. ***With this type of output, volts and amperes are the same until work(resistivity) is introduced.***

THE INVERTER MODULE:

1. Inverts to direct current (D C.)
2. Inverts to alternating current (A C), as desired.
3. Provides customized output of electrical power ready for designated usage

ELECTRICAL ENERGY REFERENCE POINTS

Electrical Energy Generating System
Patent Pending # 08/100.074. 2/4/92

The word "electric" comes from the Latin word electron "amber". When rubbed, amber develops an electrical charge, which can be transferred to a dissimilar substance. During the seventeenth and eighteenth centuries, a great deal of attention was centered on this attribute of amber. Amber was used to differentiate the non-metals. Carbon-related substances and other non-metals, when subjected to friction, give up negative electrical charges. On the other hand, metals when subjected to friction, simply conduct the charge. It is important to note that approximately 70% of the Earth's exposed crustal portions (surface) consist of silicone related non-metals (electron donors) and therefore becomes a direct source of electrical energy when properly agitated.

Useful electrical energy is obtained by grounding into the Earth's non-metal crust and into it's atmosphere as a natural source of electrons. These electrons have accumulated from the solar plasma during the aging of the Earth for more than 4.5 billion years, at a rate exceeding 3.9 exajoules per year. This indicates that the Earth's electrical field contains in excess of 17.6 x 10^{18} power of cumulative exajoules of energy. One exajoule is the approximate energy equivalent of 125 million barrels of oil. The electrical energy in one display of lightning is approximately ten trillion joules. During each 24 hour period, the land portions of the Earth's surface yields in excess of 200,000 emissions, which involves more than 2,000 quadrillion watt-seconds of active energy on display.

This physical phenomenon indicates that the Earth's crust is an unending source of electrical energy. The surface area involved is a very small portion of the Earth's crust.

J.C. Maxwell (1891) suggested that an active electron field gives rise to an associated magnetic field. Therefore, both are present with pulsating current. Early studies, involving observation of compass needles by microscopy, revealed that the needle vibrates as with alternating current. More recent studies by A. Nishida and others, confirm that alternating current is common in the Earth's crust.

C.F. Gauss (1777-1855) and H.C. Oersted (1777-1851), both were separately trying to define the Earth's electrical field with all external influences removed. These external influences being solar-quiet periods and being remote from the land's surface. The air electricity background which they measured varies with latitude. Their European measurements correspond to approximately the latitude of Washington, D.C. They were measuring magnetic field flux as an indicator of negative electron energy active and present.

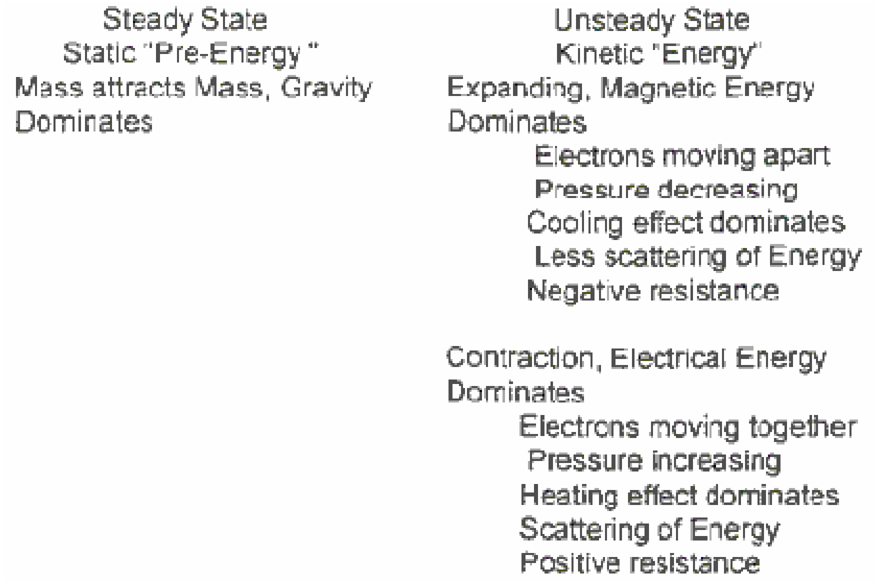
A related family of measurement is now presented. Units of measurement used to define flux fields include Gauss (one unit = 100,000 volts), Oersted (one unit - 50,000 volts), Tesla (one unit = 10,000 Gauss) and Gamma (one unit = 1/10,000 th of a Gauss). Much confusion exists in electrical related publications about these units. As presented here, they are correct with values taken from their original definitions.

The entire surface of the Earth has been surveyed by aerial magnetometer, in most cases using gamma or nano teslas. One gamma is the magnetic flux equivalent of 10 active volts of electricity. When this data is corrected for flight height, it becomes obvious that there are numerous areas where the gamma readings exceed one trillion gammas. Lightning strikes from the ground up are in that energy range. With knowledge of these electron enriched areas, the quality of Earth grounding, becomes enhanced.

The correction necessary for land surface data when acquired from aerial magnetometer maps (using the inverse square law) requires that the remote distance be squared and then multiplied by the remote reading. For example, if the reading is 1,600 gammas and the flight height is 1,000 feet. Take 1,000 x 1,000 = 1,000,000 x 1,600 gammas = 1.6 trillion gammas x 10 volts = 16 trillion volts equivalent for land surface data.

Present day methodology requires mechanical energy to be expended in exchange for electrical energy. Any required amount of electricity is available by resonant induction transfer from the Earth's magnetic and electrical fields. Each cycling of this resonant induction system pulls in additional electrons, generating energy in any required amount. A small amount of electrical energy is used to activate and pull into the system a much larger amount of energy.

ENERGY VERSUS MASS



Steady State Static "Pre-Energy " Mass attracts Mass, Gravity Dominates	Unsteady State Kinetic "Energy"
	Expanding, Magnetic Energy Dominates Electrons moving apart Pressure decreasing Cooling effect dominates Less scattering of Energy Negative resistance
	Contraction, Electrical Energy Dominates Electrons moving together Pressure increasing Heating effect dominates Scattering of Energy Positive resistance

Functions of active Electrons

Electrons become active when placed inside the critical distance allowed by their negativity.

Active Electrons provide:

1. Electricity
2. Magnetics
3. Gravitational thrust as in Electric Motors
4. The source of Visible Light
5. It's charge is Negative

They move in a closed loop as seen in the Icon for infinity, not in a circle as shown in many books. One half of the loop consist of a magnetic impulse and the return half consist of the electrical impulse. This is seen as the classic sine wave of alternating electrical energy.

A flash of light occurs when two electrons suddenly find they are too close together. Daylight results from the impingement of Electrons in the Earth's atmosphere with the Electrons of the Solar Plasma.

My Concept of the Forces of Nature differs from the conventional. It consist of a weak and a strong force, each being additionally composed of electrical, magnetic and gravitational (fields and waves). Any two of the three constitute the third member; Gravity "B" of the weak force competes with humans on a daily basis. Gravity "A" of the strong force is the force that holds the Solar System and the Universe in place. Energy from the Electrons represent the weak force. Energy inside the Atom represents the strong force "A". Controlled resonant induction of any two of the three, changes into the third and is the motor that runs the Universe. We see this in the electrically-induced magnetic thrust against gravity in electric motors.

Weak force is required to dislodge electrons and strong force (atomic) to dislodge protons. Unless dislodged, these particles are of little value in producing Conventional Electrical Energy.

Therefore, in conventional electrical energy production, the particle of importance is the negative electron. Electrons have a "grudging" relationship with other electrons. They like each other, especially at arms length. Like potentials repel each other, and unlike potentials attract. To demonstrate this, take two batteries of the same type, but of a different charge level (unequal potentials). Put the plus and minus ends facing the same direction. Then with a volt meter, measure the electrical potential between the two negative ends and then the two positive ends. It is obvious that the "more negative" moves to the "less negative" is the correct concept for electrical energy generation. Electrical Energy flow consist of a higher concentration of electrons moving to an area of lesser concentration.

OHM'S LAW WITH CORRECTIONS:

A major obstruction in reference to the correct function of electrical energy is the establishment's incorrect interpretation of Ohm's Law. The corrected version is:

Volts = Energy Available (Potential)

Ohm = Scattering, dissipation of Energy (Load)

Ampere = the rate of, dissipation / scattering of energy

It is important to note that Ohm and Ampere are after the fact, and are not decisive except for the dissipation factor. High Voltage at low amperage simply means that the High Voltage is still intact for future usage. In no way is the potential diminished by low amperage.

EXAMPLES OF OVERUNITY

Dominos did not exist in England when the Laws of Conservation were originally put in place. Otherwise they might have been very different. For example, let us take a long row of upright dominos, (many thousands) and flip number one. The Energy required to flip the first domino must now be added with that of thousands more in order to have a correct assessment.

The Electron itself is an excellent example of over-unity. The electron provides various forms of energy continuously throughout eternity and is in no way diminished. It simply cycles through the system and is available thereafter.

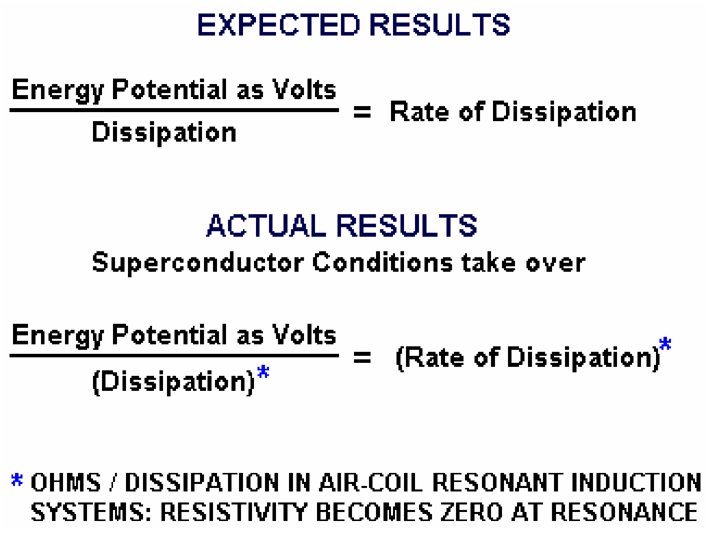
In Electrical Systems, Electrons active at point "A" are not the same Electrons active at point "B". That is to say, the Electrons activated at the Central Electrical Energy Station are not the ones used at your house. When you ground your system by flipping the wall switch, you use your own electrons. In closed energy systems, electrons communicate with and replicate the activity of the overbalanced potential, when provided with Earth and or Air Groundings.

The number of Radio sets and Television sets running at any one time do not diminish, in any way the electrical output of the source station.

For example, let now use an Air Coil Resonant Induction System for the purpose of flipping some electrons. The flipping device (reactor coil L-1) is pulsed, which then provides a resonant induction pulse. In turn, this flips the electrons present at the (reactant L-2) Coil. The energy input in L-1 is divided by the number of turns present. The induced magnetic pulsing in turn flips the electrons in each turn of L-2. If more turns are present in L-2 than L-1, there is a net gain in the Energy present, as demonstrated by the dominos above. The farads and henrys of the resonant system provide the resonant frequency when pulsed by an external energy system. A system shunt in the resonant circuit sets the containment level for energy potential.

The Induction Process itself provides an excellent example of over-unity. When comparing rate of induction, the cycles per second must be squared and then compared to the square of the second System. Let us then compare the 60 c.p.s. System with my 220 MHz Device. Energy produced at radio frequency has several major advantages over the conventional system. Ohm's Law does not apply to a resonant air-core radio frequency system.

For example: When the system is resonant, the following is true:



EXPECTED RESULTS

$$\frac{\text{Energy Potential as Volts}}{\text{Dissipation}} = \text{Rate of Dissipation}$$

ACTUAL RESULTS

Superconductor Conditions take over

$$\frac{\text{Energy Potential as Volts}}{(\text{Dissipation})^{*}} = (\text{Rate of Dissipation})^{*}$$

* OHMS / DISSIPATION IN AIR-COIL RESONANT INDUCTION SYSTEMS: RESISTIVITY BECOMES ZERO AT RESONANCE

This is named the V.A.R. (Volt Amperes Reactive) System.

When compared to the Conventional Under-Unity iron-core transformer system, the results are over-unity. It is strange that mechanical advantage as in pulleys, gears, levers and others which correspond to the electrical advantage above mentioned, are not considered over-unity devices.

Let us take a closer look at resonant induction. As an example, let a room full of ping pong balls randomly bouncing at a high speed represent the Conventional method of under-unity energy generation. Suppose that by resonant induction the balls all move in the same direction at the same time. When this occurs a huge amount of energy not previously available is present. The resonant air-core coil system lines up the electrons in such a manner that the energy factor is nearly 100 % , and not the 2% or 3% of Conventional under-unity devices sanction by the establishment.

Some other devices where overunity is common would be resonant induction circuits present in conventional radio tubes (high plate voltage), negative-feedback systems found in Op-Amps and possibly others.

SUMMARY

Useful electrical energy is achieved when the electron density at point "A" becomes greater than at point "B", (being the more-negative moving to the less-negative concept). Coils moving through a magnetic field or vice versa causes this imbalance.

The mindset of the professional Electrical Engineer is restricted to non-resonant and iron-core coil resonant systems. Ohm's Law, when applied to resonant air-core induction systems, becomes, system resistivity (impedance, Z). "Z" becomes zero at resonance. Therefore, in this system, volts and amperes are equal until load (resistivity) is introduced. This is called the Volt Ampere Reactive (V.A.R.) System. With impedance being zero, the System grounding is coupled directly into the Earth's immense electrical potential. Efficiency of induction relates to the square of the cycles per second. Compare the ratio of the conventional 60 c.p.s. System and the 220 million plus cycles of my Earth Electrical System II.

Electrons which cycle through this system, after being used, are returned intact to their former state for future usage.

Electron spin causes electrical current and magnetic lines of force

The effect of current, results from the unequal distribution of negativity (electrons).

Magnetic imbalance causes the gravitational effect. This is evidenced in electric motors by magnet-gravitational displacement of mass which causes the motor to rotate.

The System is an extension of present technology.

The System and it's source utilizes magnetometer studies.

This System (Earth Electrical System II. "EES.II") utilizes a fully renewable energy source.

This System utilizes a non-polluting energy source.

This System utilizes an universally available energy source.

Endorsement and Certification of The System can be anticipated by States with pollution problems.

AIR CORE INDUCTION COIL BUILDERS GUIDE

DONALD L. SMITH

Energy Consultant

1. Decide frequency. Considerations are: (economy of size)

- **a.** Use radio frequency upward (above 20,000 Hz).
- **b.** Use natural frequency (coils have both capacitance and inductance), that is match the wire length of the wire in the coil to the desired frequency.
- **c.** Wire length is either one quarter, one half or full wave length.
- **d.** To obtain the wire length (in feet) use the following: If using one quarter wave length divide 247 by the desired frequency (megahertz range is desirable). If using one half wave length divide 494 by the desired frequency. If using full wave length divide 998 by the desired frequency.

2. Decide number of turns, ratio of increase in number of turns sets the function. In the case of the L-1 coil, each turn divides the input voltage by the number of turns. In the case of L-2 coil, the resulting voltage in each turn of L-1 is induced into each turn of L-2, adding up with each turn. For example if the input into L-1 from a high voltage, low amperage module is 2,400 volts, and L-1, for example, has 10 turns, then each turn of L-1 will have 240 volts of magnetic induction which transfers 240 volts of electricity to each turn of L-2. L-2 may be one turn or many turns, such as 100 to 500 or more turns. At 100 turns, 24,000 volts would be produced. At 500 turns, 120,000 volts would be produced.

3. Decide the height and diameter of the coil system. The larger the diameter of the coil, the fewer turns are required, and the coil has a lesser height. In the case of L-2 this results in lowering the amplification of the induced voltage from L-1.

4. For example, if 24.7 MHz is the desired frequency output from L-2. One quarter wave length would be 247 divided by 24.7 which equals 10 feet of wire. The number of turns will be the amplification factor. The coil may be wound on standard size P.V.C. or purchased from a supplier. The supplier is normally a ham radio supply source. Once the length is determined and the number of turns decided, move to the next step. For example, let each turn of L-1 have 24 volts and desired output of L-2 be 640 volts. Therefore L-2 needs 26.67 turns. It has been determined that the wire length for one quarter wave length is 10 feet. The number of inches in 10 feet is 120. Using Chart "A" supplied look for next higher number of turns showing (being between 20 and 30 turns with a 2" diameter coil). This tells us to use a 2" coil. If ready-made as in the case of Barker and Williamson, 10 Canal Street, Bristol, Penna., 215-788-5581, the coils come in standard sizes of 4, 6 and 10 turns per inch. For higher "Q" use wider spacing of the turns. These coils come in a ready-made length of 10 inches. Select from the coil 30 turns and put input clamps on the base of the coil and at 30 turns. For exact determination of the correct position of the output clamp, use an externally grounded voltage probe. The node of maximum intensity, being the natural resonant point. Off the shelf multimeters are not radio frequency responsive. The easiest way to accomplish the above is to get from the hardware store or Radio Shack a voltage detector having a neon bulb system (Radio Shack Cat. No. 272-1100b, NE2-Neon Lamps) will work. With your hand as a ground, move the wire extension of the neon lamp along the coil surface until the neon is brightest. This is the desired point of resonance and it is the optimum connection point.

5. The input power now needs consideration. A 2,400 High Voltage module has been previously selected. This module can be made from a diode bridge or any combination of voltage amplifiers. The one used here is an off-the-shelf type, similar to those used for laser technology.

6. Construction of the input L-1 coil. It has already been decided that there will be 10 turns. The length of the wire here is not critical. Since the L-2 coil is 2-inches in diameter, the next off-the-shelf larger size may be used for L-1. Use a 3" diameter off-the-shelf coil which has 10 turns to the inch. Remove (cut) a 10 turn portion from the larger coil. Use an L.C.R. meter and measure the natural farads (capacitance) and henrys (inductance) values of the L-2 coil. Now do the same for the L-1 coil. It will be necessary to put a capacitor across the voltage input of L-1 in order to match the L-1 coil to the L-2 coil. A spark gap across L1 is also required to deal with the return voltage from L-1. A tuneable capacitor of the pad ("trimmer") type for L-1 is desirable.

7. The performance of the L-2 coil can be further enhanced by having an Earth grounding from the base of the coil. The maximum voltage output will be between the base and the top of the L-2 coil. Lesser voltages can be obtained at intermediate points along the length of the L-2 coil.

ELECTRICAL PRINCIPLES: TERMINOLOGY & SAFETY

The use of electricity is so commonplace that most people assume that it will always be available on demand. To fully realize our dependence upon electricity, consider the ways in which electricity is being used each day in the home, on the farm and the ranch. Electricity is doing more to increase work efficiency and promote enjoyable living than any other single factor. The use of electricity has grown to the extent that an increasing portion of the home or business budget, is used in paying for this source of energy.

1. Definition of Electricity

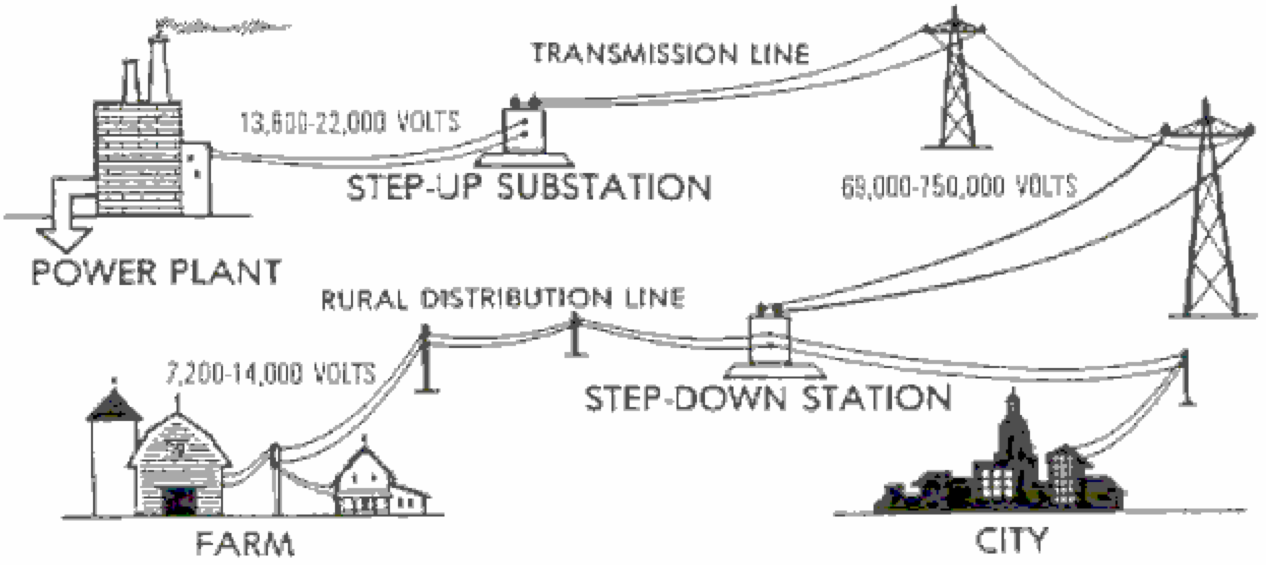
Electricity can be defined in several ways. The layman defines electricity as a source of energy that can be converted to light, heat, or power. Electrical Engineers define electricity as a movement of electrons caused by electrical pressure or voltage. The amount of energy produced depends on the number of electrons in motion.

2. The Manufacture and Distribution of Electricity

Electricity is produced from generators that are run by water, steam, or internal combustion engines. If water is used as a source of power to turn generators, it is referred to as hydroelectric generation. There are a number of this type located in areas where huge dams have been built across large streams.

Steam is used as a source of power for generating much of today's electricity. Water is heated to a high temperature, and the steam pressure is used to turn turbines which generate electricity. These are referred to as thermal-powered generators. Fuels used to heat the water are coal, natural gas, and/or fuel oil.

Generators at the power plant generate from 13,800 to 22,000 volts of electricity. From the power plant, electricity is carried to a step-up sub-station which, through the use of transformers, increases the voltage from 69,000 to 750,000 volts. This increase in voltage is necessary for the efficient transmission of electricity over long distances. From the step-up sub-station, the electricity is carried on transmission lines to a step-down sub-station which reduces the voltage to 7,200 to 14,000 volts for distribution to rural and city areas.



TRANSMISSION LINE
13,800-22,000 VOLTS
STEP-UP SUBSTATION
69,000-750,000 VOLTS
POWER PLANT

3. Common Electrical Terms

In order to work safely and efficiently with electricity and have the ability to converse on the subject, the following terms should be understood:

Ampere (Amp) - A measurement in units of the rate of flow of electrical current. This may be compared with the rate of flow of water in gallons per minute.

Example: A 60-watt incandescent lamp on a 120V circuit would pull 1/2 ampere of electricity (60 divided by 120 = 0.5 or 1/2, Formula: Amperes = Watts / Volts

Volt (V) - A unit of measure of electrical pressure. A given electrical pressure (V) causes a given amount of electrical current (Amps) to flow through a load of given resistance. Voltage may be compared to water pressure in pounds per square inch in a water system. Common service voltages are 120 volts for lighting and small appliance circuits and 240 volts for heating, air conditioning, and large equipment circuits.

Watt (W) - A unit of measure of electrical power. When applied to electrical equipment, it is the rate that electrical energy is transformed into some other form of energy such as light. Watts may be compared to the work done by water in washing a car. (Formula: Volts x Amps = Watts)

Kilowatt (KW) - A unit of measurement used in computing the amount of electrical energy used. Kilowatts are determined by dividing the number of watts by 1000 as 1 kilowatt = 1,000 watts.

Kilowatt-Hour (KWH) - A measure of electricity in terms of power in kilowatts and time in hours. One KWH is 1000 watts used for one hour.

Alternating Current (A.C.) - Electrical current that alternates or changes direction several times per second. The direction current moves depends on the direction in which the voltage forces it.

Cycle - The flow of electricity in one direction, the reverse flow of electricity in the other direction, and the start of the flow back in the other direction. The cycles per second are regulated by the power supplier and are usually 60 in America. Most electric clocks are built to operate on the mains frequency. More or fewer cycles per second would cause mains-operated clocks to gain or lose time. The present practice is to use the term Hertz (Hz) rather than "cycles per second".

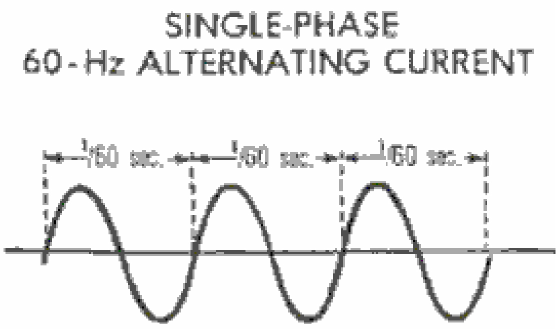
3/4
one cycle of one complete revolution



SINGLE-PHASE 60-Hz ALTERNATING CURRENT
1/60 sec.
1/60 sec.
1/60 sec.

Direct Current (D.C.) - Electrical current flowing in one direction. Example: electrical circuits in automobiles and tractors.

Transformer - A device used to increase or decrease voltage.

COIL

Single Phase - The most common type of electrical service or power available to consumers. One transformer is used between the distribution line and the meter. Usually three wires, two "hot" and one neutral, are installed to provide 120V and 240V single-phase service. Single-phase service may also be supplied with a three-phase service.

Three-Phase - This type of service is designed especially for large electrical loads. It is a more expensive installation due to three wires and three transformers being required. The important advantage of three-phase power is that the total electrical load is divided among the three phases, consequently, the wire and transformers can be smaller. Other advantages exist in the design of three-phase motors.

Short Circuit - A direct connection (before current flows through an appliance) between two "hot" wires, between a "hot" and neutral wire, or between a "hot" wire and ground.

Voltage Drop - A reduction of current between the power supply and the load. Due to resistance, there will be a loss of voltage any time electricity flows through a conductor (wire). Factors that influence voltage drop are size of wire, length of wire, and the number of amps flowing. A drop in voltage may cause a loss of heat, light, or the full power output of a motor. It could cause motor burn-out unless the motor is properly protected (time-delay fuse).

Fuse - A device used to protect circuits from an overload of current.

Circuit Breaker - A device used to protect circuits from an overload of current. May be manually reset.

Time-Delay Fuse - A fuse with the ability to carry an overload of current for a short duration without disengaging the contacts or melting the fuse link.

Horsepower (hp) - A unit of mechanical power equal to 746 watts of electrical power (assuming 74.6% electric motor efficiency). Motors of one horsepower and above are rated at 1000 watts per hp while motors below one horsepower are rated at 1,200 watts per hp.

Conductor - The wire used to carry electricity (typically, copper or aluminum). Copper and aluminum should not be spliced together due to their incompatibility resulting in deterioration and oxidation.

Insulator - A material which will not conduct electricity and is usually made of glass, Bakelite, porcelain, rubber, or thermo-plastic.

"Hot" Wire - A current-carrying conductor under electrical pressure and connected to a fuse or circuit breaker at the distribution panel. (Color Code: usually black or red)

Neutral Wire - A current-carrying conductor not under electrical pressure and connected to the neutral bar at the distribution panel. (Color Code: usually white)

Grounding - The connection of the neutral part of the electrical system to the earth to reduce the possibility of damage from lightning and the connection of electrical equipment housings to the earth to minimize the danger from electrical shock. (Color Code: Can be green or bare wire).

Underwriters' Laboratory (U.L.) - An American national organization which tests all types of wiring materials and electrical devices to insure that they meet minimum standards for safety and quality.

National Electric Code (N.E.C.) - Regulations approved by the National Board of Fire Underwriters primarily for safety in electrical wiring installations. All wiring should meet the requirements of the national as well as the local code.

4. Computing Electrical Energy Use and Cost

If an estimate of cost for electricity used is desired, the name plate data on appliances and equipment and an estimate of operating time may be used. The following formulas should be used for determining watts, amps, volts, watt-hours, kilowatt-hours, and cost.

Watts = Volts x Amperes

Amperes = Watts / Volts

Volts = Watts / Amperes

Watt-Hours = Watts x Hours of operation

Kilowatt-Hours = Watt-Hours / 1000

Cost = Kilowatt-Hours x Local Rate per Kilowatt-Hour (or per "Unit")

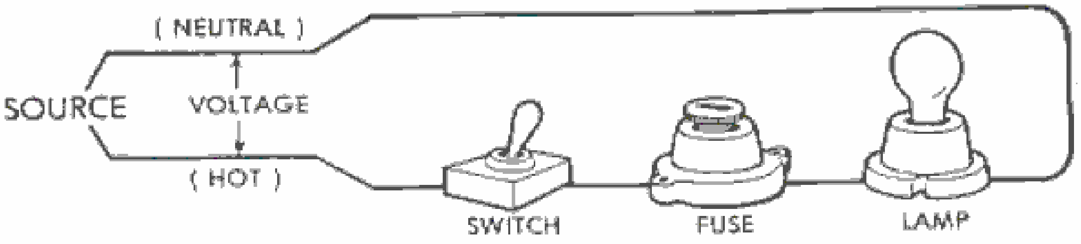
Example:

Local electricity rate per Kilowatt-Hour: 8 cents
Equipment plate data: 120 Volts 5 Amps
Monthly hours of operation: 10

1. Watts = Volts x Amperes, so Watts = 120 x 5 = 600 watts
2. Watt-Hours = 600 x 10 = 6,000 watt-hours
3. Kilowatt-Hours = 5,000 / 1,000 = 6 kilowatt-hours (or 6 Units)
4. Cost = 6 x 8 = 48 cents

5. Electrical Circuits

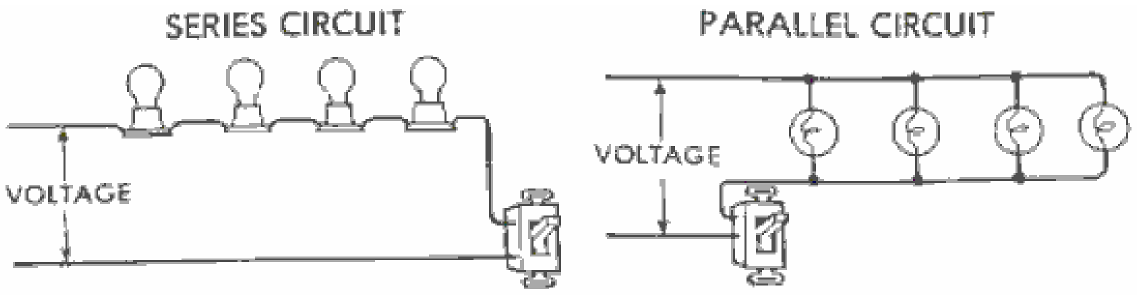
An Electrical Circuit is a completed path through which electricity flows. Insulated conductors (wires) provide the path for the flow of electricity. A water system and an electrical circuit are similar in many respects. Water flows through pipes and is measured in gallons per minute, and electricity flows through conductors and is measured in amperes. A simple circuit is shown here:



A circuit includes a "hot" wire (red or black) carrying current from the source through a switch, circuit protector (fuse or circuit-breaker), and an appliance. The neutral wire (white) conducts the current from the appliance to the source (ground).

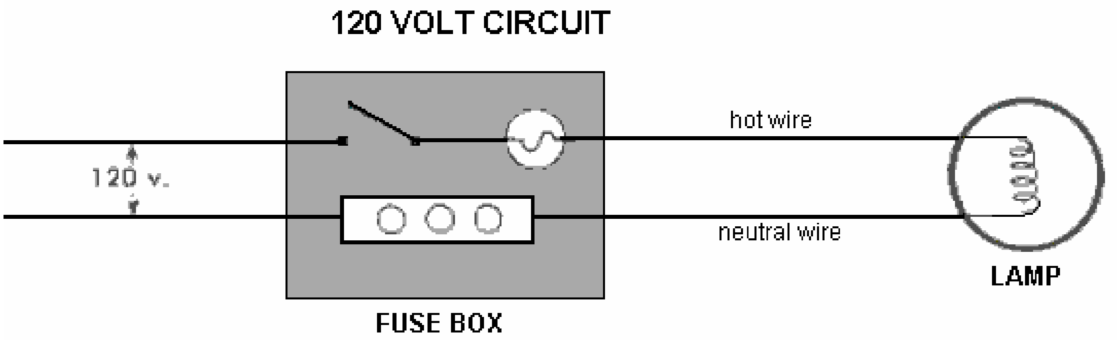
There are two methods for connecting devices in a circuit - "in series" or "in parallel". In a series circuit, all of the current must flow through each device in the circuit. Removing any one of the devices in a series circuit will stop the flow of current. In parallel circuits, the load (lights or appliances) are connected between the two wires of the circuit providing an independent path for the flow of current, and removing a lamp has no effect on the other lamps in the circuit.

Switches, fuses, and circuit breakers are always connected in series. In most cases, except for some Christmas tree lights, appliances and lights are connected in parallel.

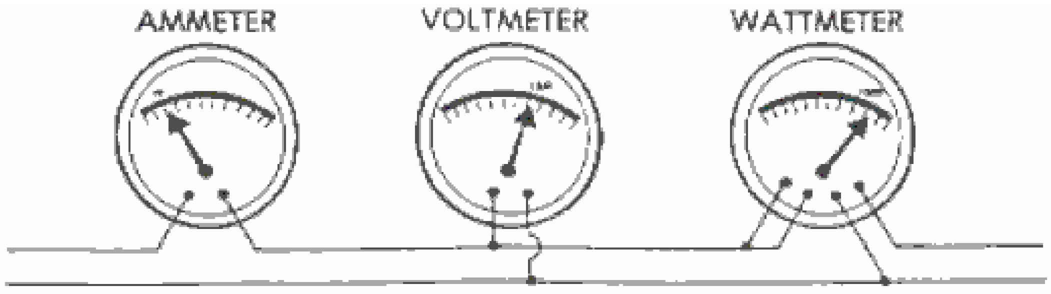


6. 120 Volt and 240 Volt Circuits

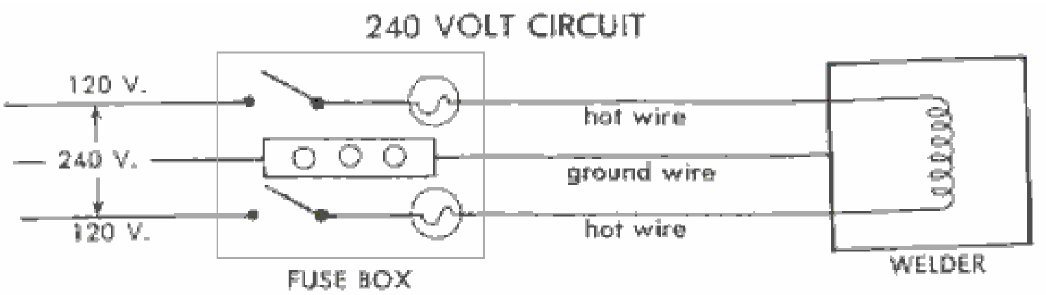
The 120V circuit has one "hot" and one neutral wire, with the switch and circuit protector in the hot line. The neutral wire from the appliance is connected to the neutral bar in the fuse or breaker box. For safety, the neutral wire should never be broken or interrupted with a switch or fuse.



The voltage in a 120V circuit is measured with a voltmeter with one lead on the hot terminal and the other lead on the neutral bar. The number of amperes flowing may be measured with a clamp-on ammeter by encircling the hot or neutral wire with the jaws of the ammeter.



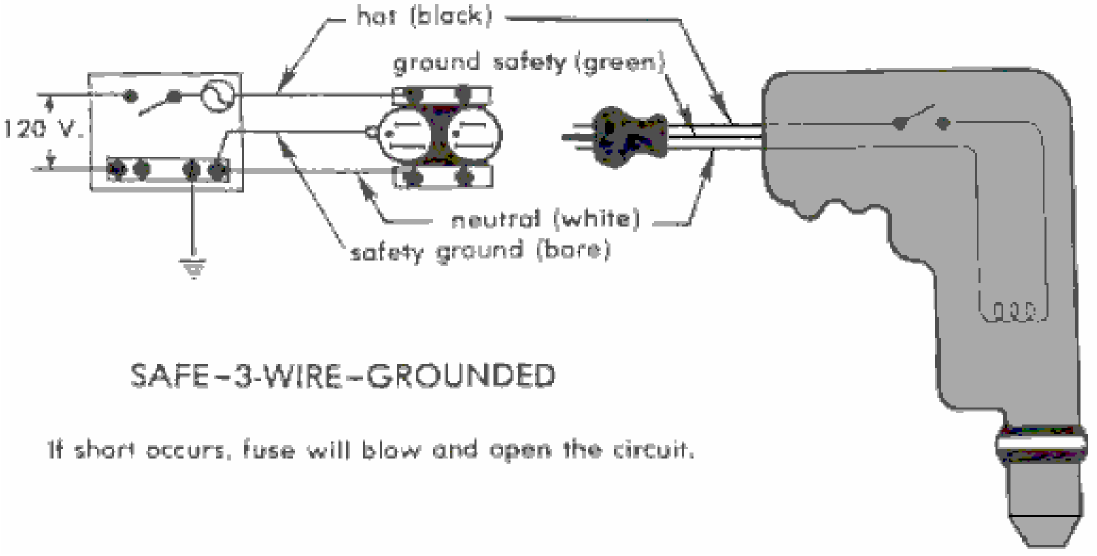
The 240V circuit has two hot wires and one safety-ground wire. Switches and fuses are installed in the hot lines. The two hot wires arc necessary for the operation of 240V welders and motors. The safety-ground wire, connected to the metal frame of the equipment or motor and to the neutral bar, does not carry current unless a "short" develops in the motor or welder. If a short should occur, one of the circuit protectors will burn-out or open, thus opening the circuit.



The voltage on a 240V circuit is measured by fastening a lead on the voltmeter to each of the hot wires. Voltage between either hot terminal and the neutral bar will be one-half of the voltage between the two hot wires. The number of amperes flowing can be measured by clamping an ammeter around either of the hot wires.

7. Safety Grounding of Electrical Equipment

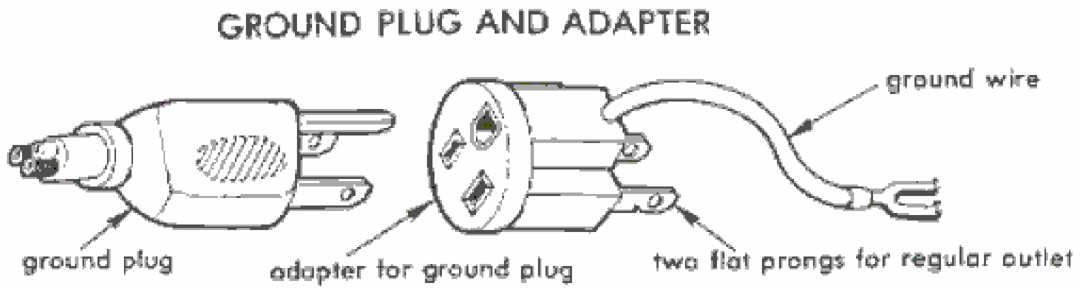
Refer back, to the 240V circuit and note the ground wire from the metal frame to the neutral bar. The following illustration shows proper safety grounding when operating a drill in a 120V circuit. The safety-ground wire may be bare, but a three-wire cable is recommended. Safety-ground wire in three-wire cable is usually green in color. A current-carrying neutral wire should never be used for a safety-ground. Likewise, a safety-ground wire should never be used as a current-carrying hot or neutral wire.



SAFE-3-WIRE-GROUNDED

If short occurs, fuse will blow and open the circuit.

Using grounded receptacles and a safety-ground on all circuits will allow the safety-grounding of appliances when they are plugged into the outlet. An adapter must be used to properly ground appliances connected to receptacles which are not safety-grounded. If an adapter is used, the green pigtail wire must be connected to a known ground to give protection from electrical shock should a short-circuit occur.



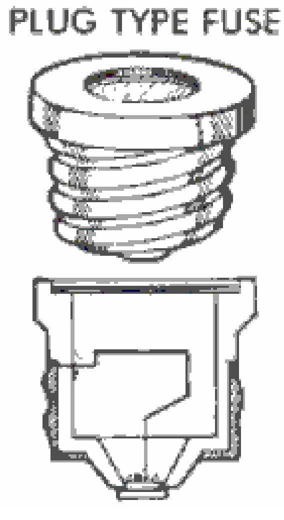
A test lamp can be used to check a circuit completed between a "hot" wire and a neutral wire. Use the test lamp to check appliances for shorts. With the appliance plugged into an outlet, touch the appliance frame with one lead of the test lamp while the other lead of the test lamp is grounded to a water or gas pipe. If the test light does not burn, reverse the appliance plug and check with the test lamp again. If the light burns, a short exists (the hot wire is touching the frame of the appliance). Unplug the appliance and repair or discard it.

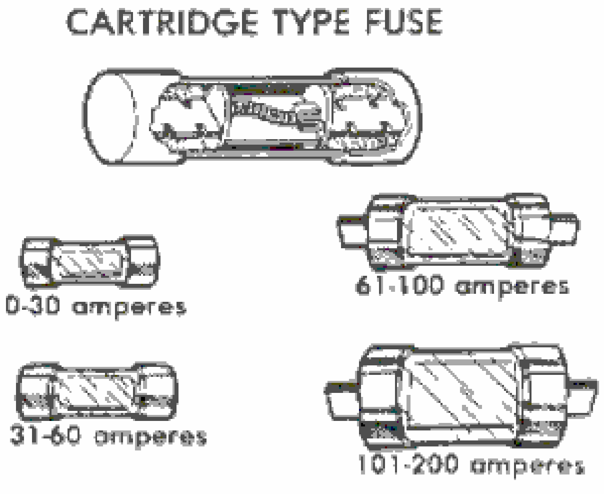
8. Electrical Circuit Protection

Electrical circuits should be protected from an overload of amperes. Too many amperes flowing through an unprotected circuit will generate heat, which will deteriorate or melt the insulation and possibly cause a fire. The number of amperes that a given conductor can safely carry, depends upon the kind and size of wire, type of insulation, length of run in feet, and the type of installation. Charts are available in reference texts giving allowable current-carrying capabilities of various conductors.

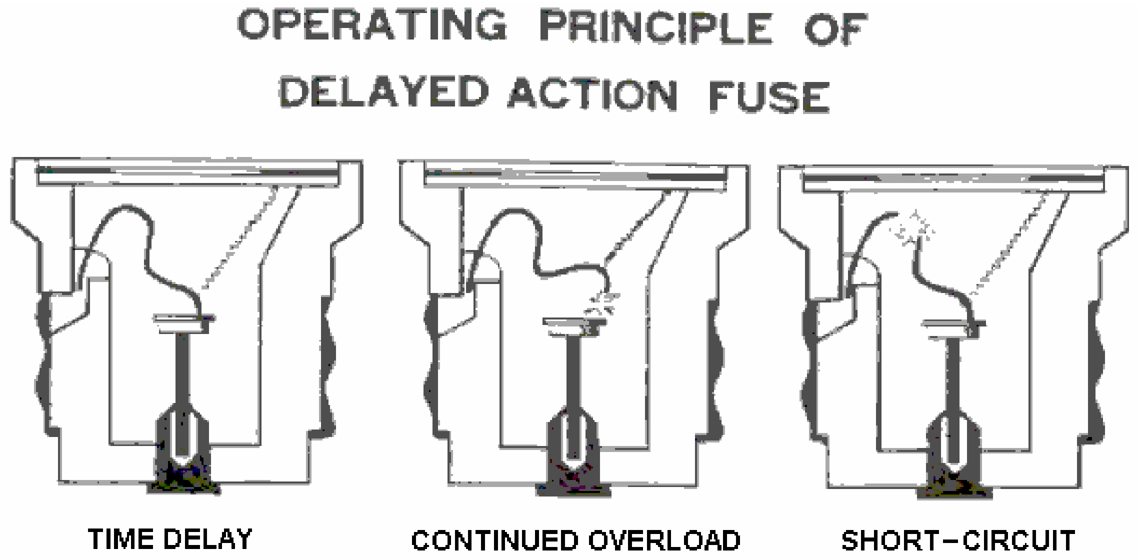
The four types of circuit protection are: common fuses, fusetrons (time-delay), fustats (two-part time-delay), and circuit-breakers. Fuses are of two basic types: plug, and cartridge.

Common fuses contain a link made from a low-temperature melting alloy which is designed to carry current up to the rating of the fuse. Current higher than the amperage rating causes the link to heat above it's melting point. When the fuse "blows", the link melts and opens the circuit.



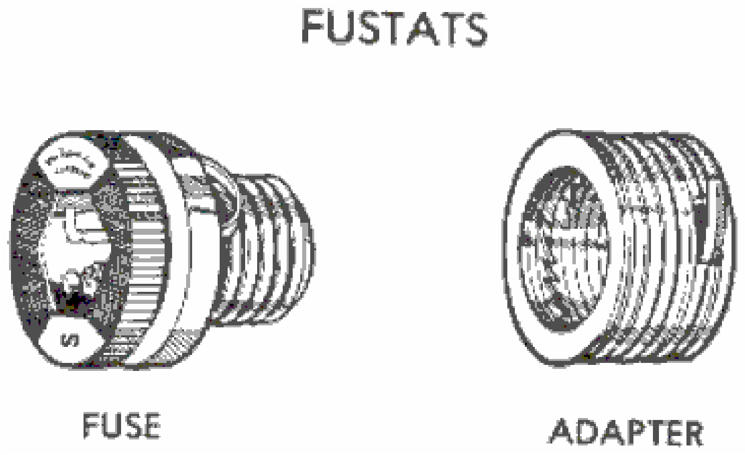


Fusetrons (time-delay fuses) are made to carry a temporary overload, such as the overload caused by the starting of an electric motor. The fuse, however, still provides protection for the circuit, and a short-circuit will melt the fuse link. If a common fuse is used, the fuse link will melt every time an electric motor starts. The use of a larger ampere common fuse will prevent the "blow" resulting from the temporary overload, but will not provide protection for the motor or the circuit.



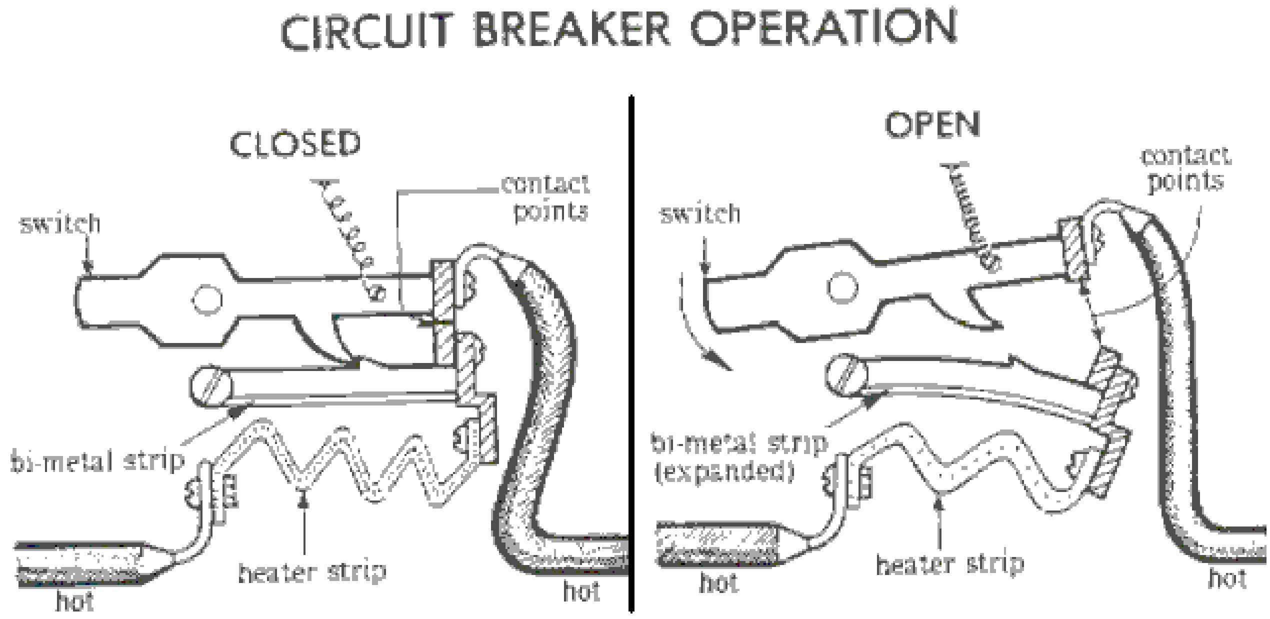
OPERATING PRINCIPLE OF
DELAYED ACTION FUSE
TIME DELAY
CONTINUED OVERLOAD
SHORT-CIRCUIT

Fustats, non-tamperable fuses of the time-delay type, have a different size base and require a special adapter which is screwed into the standard fuse socket. After the adapter is installed, it cannot be removed. For example, the installation of a 15-ampere adapter allows only the use of 15-ampere or smaller fuse.



FUSTATS
S
FUSE
ADAPTER

Circuit breakers eliminate the replacement of fuses and are commonly used even though a circuit breaker box costs more than a fuse box. Circuit breakers are of two types, thermal and magnetic. The thermal breaker has two contacts held together by a bi-metal latch. A current overload causes the bi-metallic strip to become heated, the latch releases, and the points spring open. After the bi-metallic strip cools, the switch is reset and service is restored.



CIRCUIT BREAKER OPERATION
CLOSED
switch

The magnetic breaker has contacts that are held together by a latch which is released by the action of an electromagnet. The amount of current flowing through the circuit will determine the size of the electromagnet. This type of circuit-breaker is reset by moving the toggle switch to the "on" position.

The following diagram shows the parts of a circuit breaker.

9. No Fault Grounding

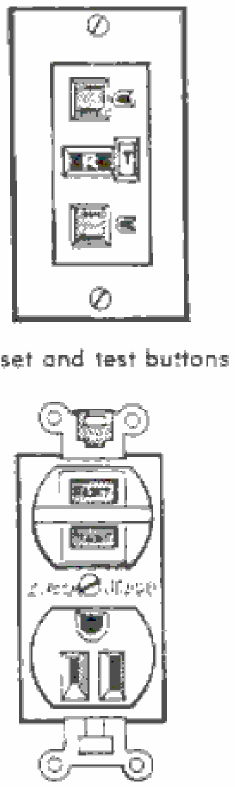
Fuses and circuit-breakers are safety devices which limit current (amperage) in a circuit. Their main function is to protect equipment and wiring from overload. Ground fault circuit interrupters (GFI) are designed to protect humans, equipment, and/or electrical systems from injury or damage if electricity flows in an unintended path (a short-circuit).

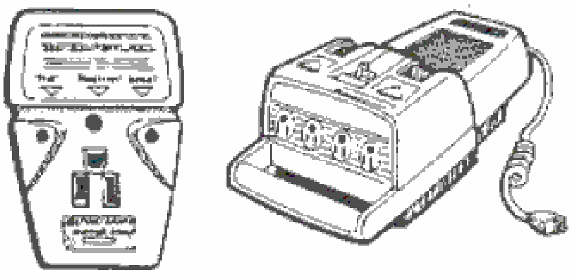
A GFI is a very sensitive device that functions by comparing the current moving in the "hot" wire with that in the neutral wire. If these two currents are not equal, a fault exists, and current is "leaking" out of the circuit. If the difference in current between the two wires is 5/1000 of an ampere or greater, the GFI will open the circuit, shutting off the power and eliminating any shock hazard.

The National Electrical Code requires GFI's for all 120V, single phase, 15 and 20 amp receptacles installed outdoors, in bathrooms, and in garages for residential buildings. A GFI is required at construction sites and some other applications. After correcting a circuit fault, the GFI may be reset for further use.

A variety of GFI equipment is made for 120 and 240 volt circuits:

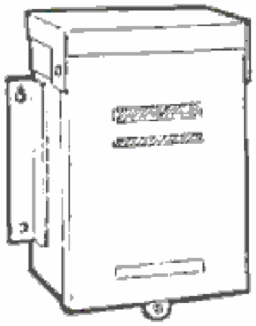
GFI RECEPTACLE FOR CONVENTIONAL OUTLET





PORTABLE GFI TO PLUG INTO OUTLET

GFI TO INSTALL IN BRANCH CIRCUIT



GFI TO REPLACE CIRCUIT BREAKER

Note: This electrical information does not apply directly to areas outside America and local regulations for electrical supply should be checked.

The following material is the section in Chapter 3 of "The Practical Guide to Free-Energy Devices" which deals with Don Smith's technology:

Don Smith. One of most impressive developers of free-energy devices is Don Smith who has produced many spectacular devices, generally with major power output. These are a result of his in-depth knowledge and understanding of the way that the environment works. Don says that his understanding comes from the work of Nikola Tesla as recorded in Thomas C. Martin's book "The Inventions, Researches, and Writings of Nikola Tesla" ISBN 0-7873-0582-0 available from http://www.healthresearchbooks.com and various other book companies. This book can be downloaded from http://www.free-energy-info.com as a pdf file, but a paper copy is much better quality and easier to work from.

Don states that he repeated each of the experiments found in the book and that gave him his understanding of what he prefers to describe as the 'ambient background energy' which is called the 'zero-point energy field' elsewhere in this eBook. Don remarks that he has now advanced further than Tesla in this field, partly because of the devices now available to him and which were not available when Tesla was alive.

Don stresses two key points. Firstly, a dipole can cause a disturbance in the magnetic component of the 'ambient background' and that imbalance allows you to collect large amounts of electrical power, using capacitors and inductors (coils). Secondly, you can pick up as many powerful electrical outputs as you want from that one magnetic disturbance, without depleting the magnetic disturbance in any way. This allows massively more power output than the small power needed to create the magnetic disturbance in the first place. This is what produces a COP>1 device and Don has created nearly fifty different devices based on that understanding.

Although they get removed quite frequently, there is one video which is definitely worth watching if it is still there. It is located at http://www.metacafe.com/watch/2820531/don_smith_free_energy/ and was recorded in 2006. It covers a good deal of what Don has done. In the video, reference is made to Don's website but you will find that it has been taken over by Big Oil who have filled it with innocuous similar-sounding things of no consequence, apparently intended to confuse newcomers. A website which is run by Conny Öström of Sweden is http://www.johnnyfg.110mb.com/ and it has brief details of his prototypes and theory. You will find the only document of his which I could locate, here http://www.free-energy-info.com/Smith.pdf in pdf form and it contains the following patent on a most interesting device which appears to have no particular limit on the output power. This is a slightly re-worded copy of that patent as patents are generally worded in such a way as to make them difficult to understand.

Patent NL 02000035 A **20th May 2004** **Inventor: Donald Lee Smith**

TRANSFORMER GENERATOR MAGNETIC RESONANCE INTO ELECTRIC ENERGY

ABSTRACT

The present invention refers to an Electromagnetic Dipole Device and Method, where wasted radiated energy is transformed into useful energy. A Dipole as seen in Antenna Systems is adapted for use with capacitor plates in such a way that the Heaviside Current Component becomes a useful source of electrical energy.

DESCRIPTION

Technical Field:

This invention relates to loaded Dipole Antenna Systems and their Electromagnetic radiation. When used as a transformer with an appropriate energy collector system, it becomes a transformer/generator. The invention collects and converts energy which is radiated and wasted by conventional devices.

Background Art:

A search of the International Patent Database for closely related methods did not reveal any prior art with an interest in conserving radiated and wasted magnetic waves as useful energy.

DISCLOSURE OF THE INVENTION

The invention is a new and useful departure from transformer generator construction, such that radiated and wasted magnetic energy changes into useful electrical energy. Gauss meters show that much energy from conventional electromagnetic devices is radiated into the ambient background and wasted. In the case of conventional transformer generators, a radical change in the physical construction allows better access to the energy available. It is found that creating a dipole and inserting capacitor plates at right angles to the current flow, allows magnetic waves to change back into useful electrical (coulombs) energy. Magnetic waves passing through the capacitor plates do not degrade and the full impact of the available energy is accessed. One, or as many sets of capacitor plates as is desired, may be used. Each set makes an exact copy of the full force and effect of the energy present in the magnetic waves. The originating source is not depleted of degraded as is common in conventional transformers.

BRIEF DESCRIPTION OF THE DRAWINGS

The Dipole at right angles, allows the magnetic flux surrounding it to intercept the capacitor plate, or plates, at right angles. The electrons present are spun such that the electrical component of each electron is collected by the capacitor plates. Essential parts are the South and North component of an active Dipole. Examples presented here exist as fully functional prototypes and were engineer constructed and fully tested in use by the Inventor. In each of the three examples shown in the drawings, corresponding parts are used.

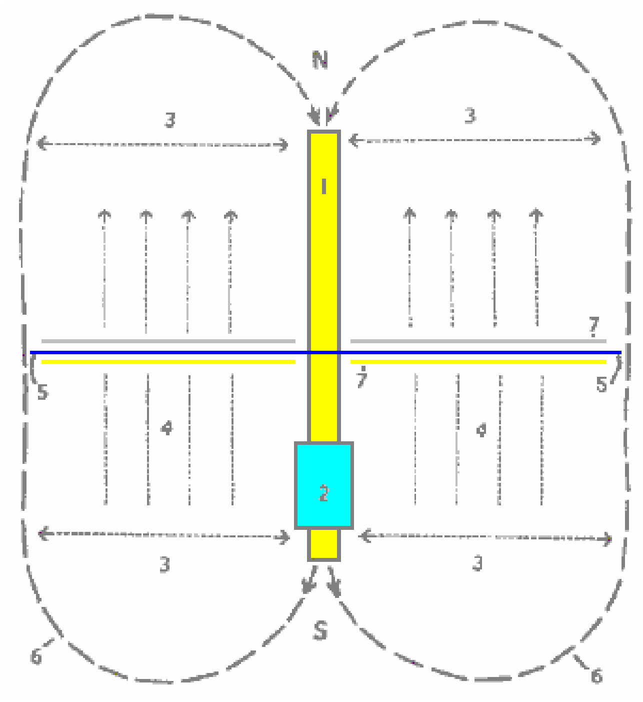

Fig.1 is a View of the Method, where **N** is the North and **S** is the South component of the Dipole.

Here, **1** marks the Dipole with its North and South components. **2** is a resonant high-voltage induction coil. **3** indicates the position of the electromagnetic wave emission from the Dipole. **4** indicates the position and flow direction of the corresponding Heaviside current component of the energy flow caused by the induction coil **2**. **5** is the dielectric separator for the capacitor plates **7**. **6** for the purposes of this drawing, indicates a virtual limit for the scope of the electromagnetic wave energy.

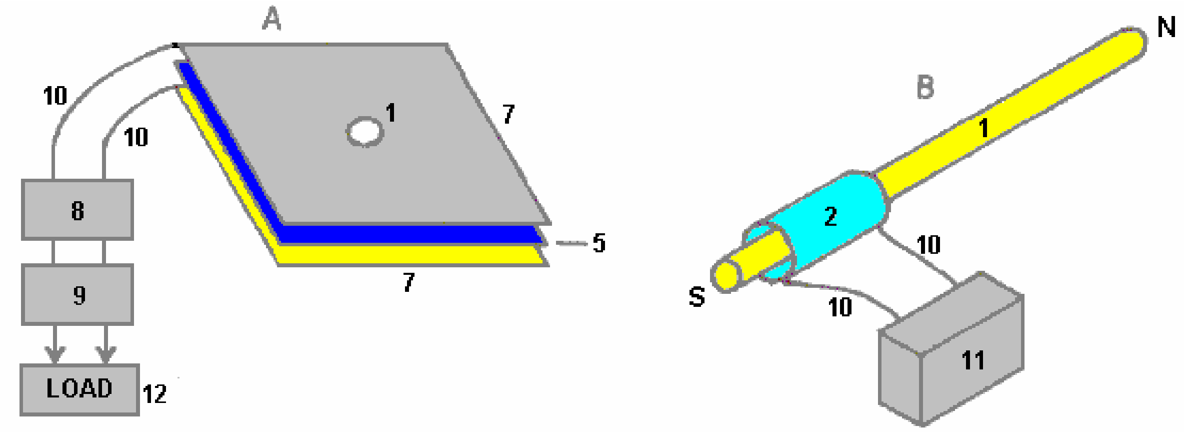

Fig.2 has two parts **A** and **B**.

In **Fig.2A** **1** is the hole in the capacitor plates through which the Dipole is inserted and in **Fig.2B** it is the Dipole with its North and South poles shown. **2** is the resonant high-voltage induction coil surrounding part of the Dipole **1**. The dielectric separator **5**, is a thin sheet of plastic placed between the two capacitor plates **7**, the upper plate being made of aluminium and the lower plate made of copper. Unit **8** is a deep-cycle battery system powering a DC inverter **9** which produces 120 volts at 60 Hz (the US mains supply voltage and frequency, obviously, a 240 volt 50 Hz inverter could be used here just as easily) which is used to power whatever equipment is to be driven by the device. The reference number **10** just indicates connecting wires. Unit **11** is a high-voltage generating device such as a neon transformer with its oscillating power supply.

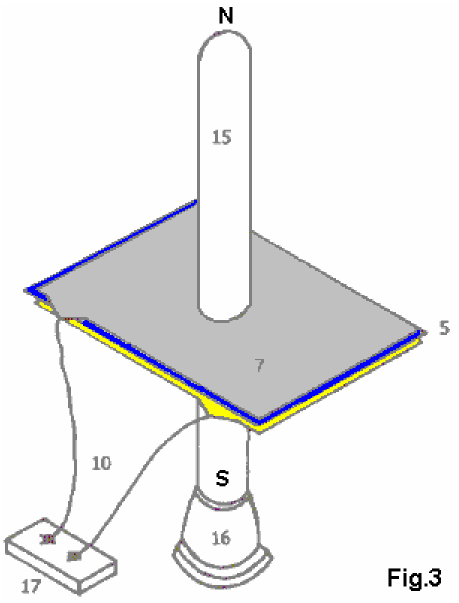

Fig.3

Fig.3 is a Proof Of Principal Device using a Plasma Tube as an active Dipole. In this drawing, **5** is the plastic sheet dielectric separator of the two plates **7** of the capacitor, the upper plate being aluminium and the lower plate copper. The connecting wires are marked **10** and the plasma tube is designated **15**. The plasma tube is four feet long (1.22 m) and six inches (100 mm) in diameter. The high-voltage energy source for the active plasma dipole is marked **16** and there is a connector box **17** shown as that is a convenient method of connecting to the capacitor plates when running tests on the device.

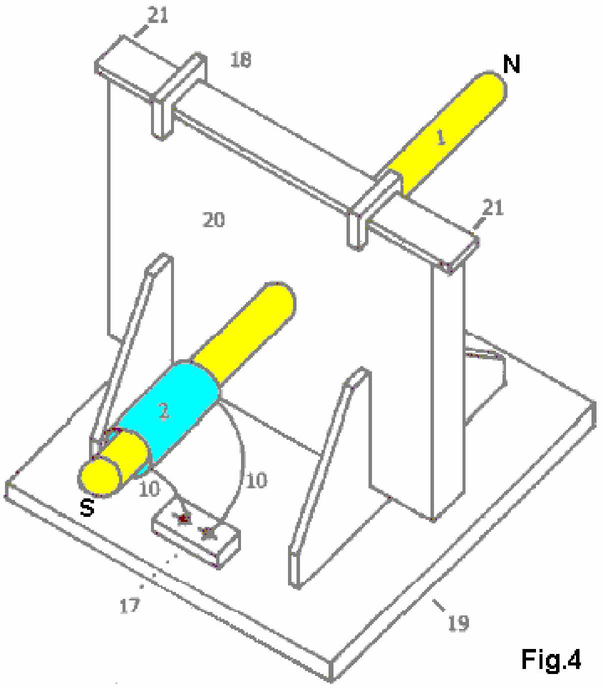

Fig.4

Fig.4 shows a Manufacturer's Prototype, constructed and fully tested. **1** is a metal Dipole rod and **2** the resonant high-voltage induction coil, connected through wires **10** to connector block **17** which facilitates the connection of it's high-voltage power supply. Clamps **18** hold the upper edge of the capacitor packet in place and **19** is the base plate with it's supporting brackets which hold the whole device in place. **20** is a housing which contains the capacitor plates and **21** is the point at which the power output from the capacitor plates is drawn off and fed to the DC inverter.

BEST METHOD OF CARRYING OUT THE INVENTION

The invention is applicable to any and all electrical energy requirements. The small size and it's high efficiency make it an attractive option, especially for remote areas, homes, office buildings, factories, shopping centres, public places, transportation, water systems, electric trains, boats, ships and 'all things great and small'. The construction materials are commonly available and only moderate skill levels are needed to make the device.

CLAIMS

1. Radiated magnetic flux from the Dipole, when intercepted by capacitor plates at right angles, changes into useful electrical energy.

2. A Device and Method for converting for use, normally wasted electromagnetic energy.

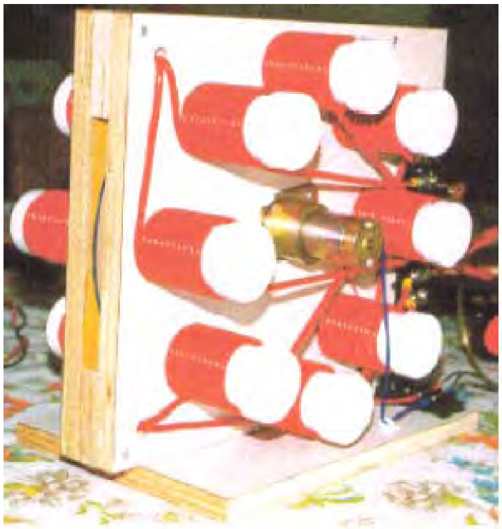
3. The Dipole of the Invention is any resonating substance such as Metal Rods, Coils and Plasma Tubes which have interacting Positive and Negative components.

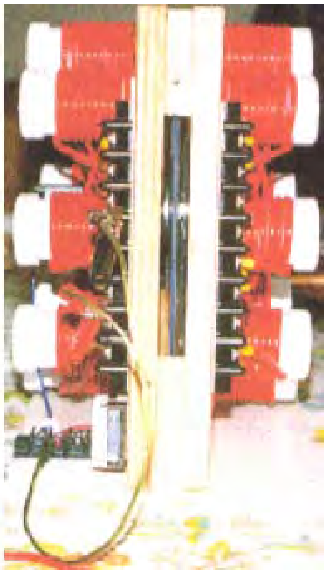
4. The resulting Heaviside current component is changed to useful electrical energy.

****

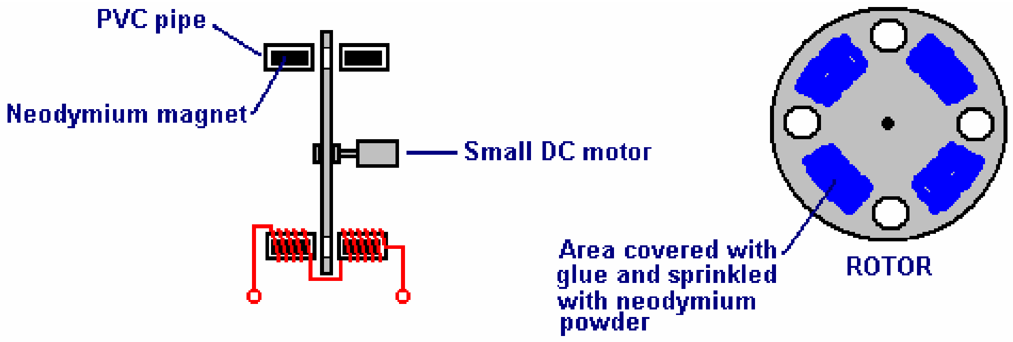
This patent does not make it clear that the device needs to be tuned and that the tuning is related to its physical location. The tuning will be accomplished by applying a variable-frequency input signal to the neon transformer and adjusting that input frequency to give the maximum output.

Don Smith has produced some forty eight different devices, and because he understands that the real power in the universe is magnetic and not electric, these devices have performances which appear staggering to people trained to think that electrical power is the only source of power. One of his devices is shown here:



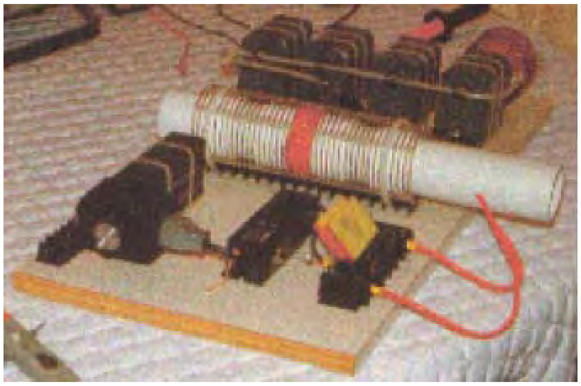


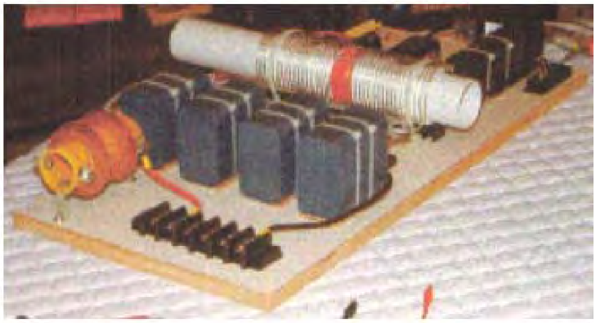
This is a small table-top device which looks like it is an experiment by a beginner, and something which would be wholly ineffective. Nothing could be further from the truth. Each of the eight coils pairs (one each side of the rotating disc) produces 1,000 volts at 50 amps (fifty kilowatts) of output power, giving a total power output of 400 kilowatts. It's overall size is 16" x 14.5" x 10" (400 x 370 x 255 mm). In spite of the extremely high power output, the general construction is very simple:



The device operates on a fluctuating magnetic field which is produced by a small low-power DC motor spinning a plastic disc. In the prototype shown above, the disc is an old vinyl record which has had holes cut in it. Between the holes is an area which was covered with glue and then sprinkled with powdered neodymium magnet material. It takes very little power to spin the disc, but it acts in a way which is very much like the Ecklin-Brown generator, repeatedly disrupting the magnetic field. The magnetic field is created by a neodymium magnet in each of the sixteen plastic pipes. It is important that the change in the magnetic flux between the matching magnets on each side of the disc is as large as possible. The ideal rotor material for this is "Terfenol-D" (tungsten zirconate) with slots cut in it but it is so expensive that materials like stainless steel are likely to be used instead. Please understand that all of Don's designs rely on resonant operation and so the coil impedance has to be matched to the pulse frequency used to drive the coil.

For Don Smith, this is not an exceptional device. The one shown below is also physically quite small and yet it has an output of 160 kilowatts (8000 volts at 20 amps) from an input of 12 volts 1 amp (COP = 13,333):

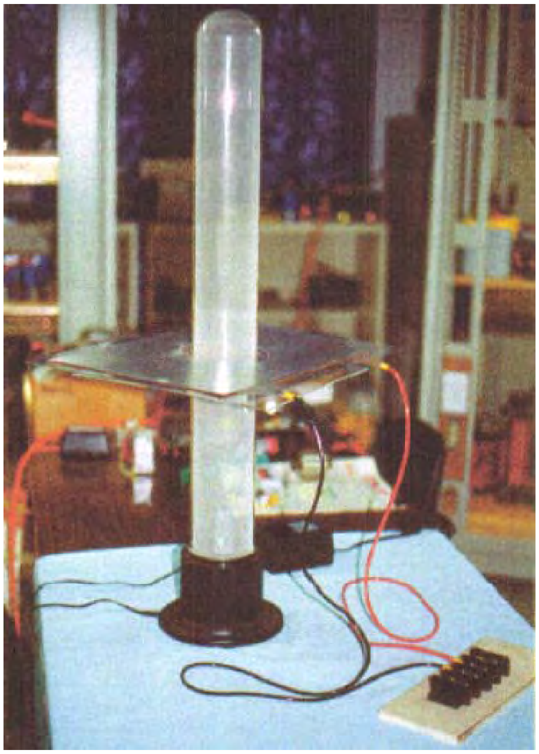




Again, this is a device which can be placed on top of a table and is not a complicated form of construction, having a very open and simplistic layout. However, some components are not mounted on this board. The twelve volt battery and connecting leads are not shown, nor is the ground connection, the step-down isolation transformer and the varistor used to protect the load from over-voltage by absorbing any random voltage spikes which might occur, but more of these things later on when a much more detailed description of this device is given. Again, please understand that Don does not reveal all of the details of any of his designs, and he deliberately omits to mention various important details, leaving us to deduce what is missing from our own understanding of how these devices work.

The device shown above is a typical example of this with various subtle points glossed over in spite of this being one device which Don says that we should be able to reproduce ourselves. Let me state here that reproducing this seemingly simple design of Don's is not an easy thing to do and it is not something which can be thrown together by a beginner using whatever components happen to be at hand at the time. Having said that, with careful study and commonsense application of some obvious facts, it should be possible to make one of these devices.

Another of Don's devices is shown here:



This is a larger device which uses a plasma tube four feet (1.22 m) long and 6 inches (100 mm) in diameter. The output is a massive 100 kilowatts. This is the design shown as one of the options in Don's patent. Being an Electrical Engineer, none of Don's prototypes are in the "toy" category. If nothing else is taken from Don's work, we should realize that high power outputs can be had from very simple devices.

There is one other brief document "Resonate Electrical Power System" from Don Smith which says:

Potential Energy is everywhere at all times, becoming useful when converted into a more practical form. There is no energy shortage, only grey matter. This energy potential is observed indirectly through the manifestation of electromagnetic phenomenon, when intercepted and converted, becomes useful. In nonlinear systems, interaction of magnetic waves amplify (conjugate) energy, providing greater output than input. In simple form, in the piano where three strings are struck by the hammer, the centre one is impacted and resonance activates the side strings. Resonance between the three strings provides a sound level greater than the input energy. Sound is part of the electromagnetic spectrum and is subject to all that is applicable to it.

"Useful Energy" is defined as "that which is other than Ambient". "Electric Potential" relates to mass and it's acceleration. Therefore, the Earth's Mass and Speed through space, gives it an enormous electrical potential. Humans are like the bird sitting unaware on a high voltage line. in nature, turbulence upsets ambient and we see electrical displays. Tampering with ambient, allows humans to convert magnetic waves into useful electricity.

Putting this in focus, requires a look at the Earth in general. During each of the 1,440 minutes of each day, more than 4,000 displays of lightning occur. Each display yields more than 10,000,000 volts at more than 200,000 amperes in equivalent electromagnetic flux. This is more than 57,600,000,000,000 volts and 1,152,000,000,000 amperes of electromagnetic flux during each 24 hour period. This has been going on for more than 4 billion years. The USPTO insist that the Earth's electrical field is insignificant and useless, and that converting this energy violates the laws of nature. At the same time, they issue patents in which, electromagnetic flux coming in from the Sun is converted by solar cells into DC energy. Aeromagnetic flux (in gammas) Maps World-Wide, includes those provided by the US Department of Interior-Geological Survey, and these show clearly that there is present, a spread of 1,900 gamma above Ambient, from reading instruments flown 1,000 feet above the (surface) source. Coulomb's Law requires the squaring of the distance of the remote reading, multiplied by the recorded reading. Therefore, that reading of 1,900 gamma has a corrected value of 1,900 x 1,000 x 1,000 = 1,900,000,000 gamma.

There is a tendency to confuse "gamma ray" with "gamma". "Gamma" is ordinary, everyday magnetic flux, while "gamma ray" is high-impact energy and not flux. One gamma of magnetic flux is equal to that of 100 volts RMS. To see this, take a Plasma Globe emitting 40,000 volts. When properly used, a gamma meter placed nearby, will read 400 gammas. The 1,900,000,000 gamma just mentioned, is the magnetic ambient equivalent of

190,000,000 volts of electricity. This is on a "Solar Quiet" day. On "Solar Active" days it may exceed five times that amount. The Establishment's idea that the Earth's electrical field is insignificant, goes the way of their other great ideas.

There are two kinds of electricity: "potential" and "useful". All electricity is "potential" until it is converted. The resonant-fluxing of electrons, activates the electrical potential which is present everywhere. The Intensity/CPS of the resonant-frequency-flux rate, sets the available energy. This must then be converted into the required physical dimensions of the equipment being used. For example, energy arriving from the Sun is magnetic flux, which solar cells convert to DC electricity, which is then converted further to suit the equipment being powered by it. Only the magnetic flux moves from point "A" (the Sun) to point "B" (the Earth). All electrical power systems work in exactly the same way. Movement of Coils and Magnets at point "A" (the generator) fluxes electrons, which in turn, excite electrons at point "B" (your house). **None of the electrons at point "A" are ever transmitted to point "B"**. In both cases, the electrons remain forever intact and available for further fluxing. This is not allowed by Newtonian Physics (electrodynamics and the laws of conservation). Clearly, these laws are all screwed up and inadequate.

In modern physics, USPTO style, all of the above cannot exist because it opens a door to overunity. The good news is that the PTO has already issued hundreds of Patents related to Light Amplification, all of which are overunity. The Dynode used to adjust the self-powered shutter in your camera, receives magnetic flux from light which dislodges electrons from the cathode, reflecting electrons through the dynode bridge to the anode, resulting in billions of more electrons out than in. There are currently, 297 direct patents issued for this system, and thousands of peripheral patents, all of which support overunity. More than a thousand other Patents which have been issued, can be seen by the discerning eye to be overunity devices. What does this indicate about Intellectual Honesty?

Any coil system, when fluxed, causes electrons to spin and produce useful energy, once it is converted to the style required by its use. Now that we have described the method which is required, let us now see how this concerns us.

The entire System already exists and all that we need to do is to hook it up in a way which is useful to our required manner of use. Let us examine this backwards and start with a conventional output transformer. Consider one which has the required voltage and current handling characteristics and which acts as an isolation transformer. Only the magnetic flux passes from the input winding to the output winding. No electrons pass through from the input side to the output side. Therefore, we only need to flux the output side of the transformer to have an electrical output. Bad design by the establishment, allowing hysteresis of the metal plates, limits the load which can be driven. Up to this point, only potential is a consideration. Heat (which is energy loss) limits the output amperage. Correctly designed composite cores run cool, not hot.

A power correction factor system, being a capacitor bank, maintains an even flow of flux. These same capacitors, when used with a coil system (a transformer) become a frequency-timing system. Therefore, the inductance of the input side of the transformer, when combined with the capacitor bank, provides the required fluxing to produce the required electrical energy (cycles per second).

With the downstream system in place, all that is needed now is a potential system. Any flux system will be suitable. Any amplification over-unity output type is desirable. The input system is point "A" and the output system is point "B". Any input system where a lesser amount of electrons disturbs a greater amount of electrons - producing an output which is greater than the input - is desirable.

At this point, it is necessary to present updated information about electrons and the laws of physics. A large part of this, originates from me (Don Smith) and so is likely to upset people who are rigidly set in the thought patterns of conventional science.

Non - Ionic Electrons

As a source of electrical energy, non-ionic electrons doublets exist in immense quantities throughout the universe. Their origin is from the emanation of Solar Plasma. When ambient electrons are disturbed by being spun or pushed apart, they yield both magnetic and electrical energy. The rate of disturbance (cycling) determines the energy level achieved. Practical methods of disturbing them include, moving coils past magnets or vice versa. A better way is the pulsing (resonant induction) with magnetic fields and waves near coils.

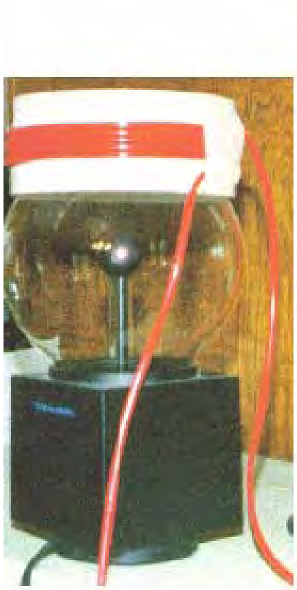
In coil systems, magnetic and amperage are one package. This suggests that electrons in their natural non-ionic state, exist as doublets. When pushed apart by agitation, one spins right (yielding Volts-potential electricity) and the other spins left (yielding Amperage-magnetic energy), one being more negative than the other. This further suggests that when they reunite, we have (Volts x Amps = Watts) useful electrical energy. Until now, this idea has been totally absent from the knowledge base. The previous definition of Amperage is therefore flawed.

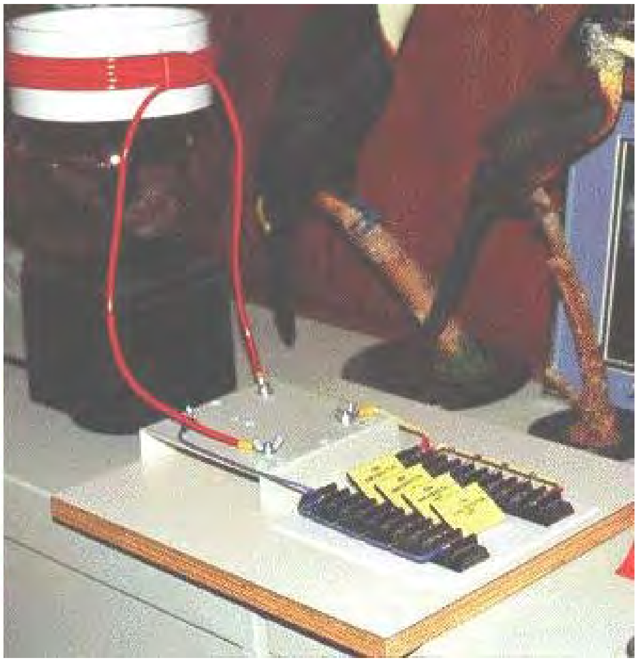
Electron Related Energy

	Energy Available	Method of Storage	Common Unit	Units of Measure
Electrons	Electrical	Capacitor/Coulombs	Volts	Flux Units
	Spin / Gravity	Momentum	Torque	Ergs
	Magnetic	Coils/Amp. turns	Amperes	Flux Units Teslas, Gauss, Gammas, Oesteds
	Light	Laser	Lux ,	Photons/Gamma Rays
	Impact / resistance			
	Heat	Various	Fahrenheit/Celsius	Temp

Left hand spin of electrons results in Electrical Energy and right hand spin results in Magnetic Energy. Impacted electrons emit visible Light and heat.

Useful Circuits, Suggestions for Building an Operational Unit





1. Substitute a Plasma Globe such as Radio Shack's "Illumna-Storm" for the source-resonant induction system. It will have about 400 milligauss of magnetic induction. One milligauss is equal to 100 volts worth of magnetic induction.

2. Construct a coil using a 5-inch to 7-inch (125 to 180 mm) diameter piece of PVC for the coil former.

3. Get about 30 feet (10 m) of Jumbo-Speaker Cable and separate the two strands. This can be done by sticking a carpet knife into a piece of cardboard or wood, and then pulling the cable carefully past the blade to separate the two insulated cores from each other. (PJK Note: "Jumbo-Speaker Cable" is a vague term as that cable comes in many varieties, with anything from a few, to over 500 strands in each core. As Don points out that the output power increases with each turn of wire, it is distinctly possible that each of these strands acts the same as individual insulated turns which have been connected in parallel, so a 500-strand cable may well be far more effective than a cable with just a few strands).

4. Wind the coil with 10 to 15 turns of wire and leave about 3 feet (1 m) of cable spare at each end of the coil. Use a glue gun to hold the start and finish of the coil.

5. This will become the "L - 2" coil shown in the Circuits page.

6. When sitting on top of the Plasma Globe (like a crown) you have a first-class resonant air-core coil system.

7. Now, substitute two or more capacitors (rated at 5,000 volts or more) for the capacitor bank shown on the Circuits page. I use more than two 34 microfarad capacitors.

8. Finish out the circuit as shown. You are now in business !

9. Voltage - Amperage limiting resistors are required across the output side of the Load transformer. These are used to adjust the output level and the desired cycles per second.

Don Smith's Suggestions: Get a copy of the "Handbook of Electronic Tables and Formulas", published by Sams, ISBN 0-672-22469-0, also an Inductance/Capacitance/Resistance meter is required. Chapter 1 of Don's pdf document has important time-constant (frequency) information and a set of reactance charts in nomograph style (*"nomograph": a graph, usually containing three parallel scales graduated for different variables so that when a straight line connects values of any two, the related value may be read directly from the third at the point intersected by the line*) which makes working, and approximating of the three variables (capacitance, inductance and resistance) much easier. If two of the variables are known, then the third one can be read from the nomograph.

For example, if the input side of the isolation transformer needs to operate at 60 Hz, that is 60 positive cycles and 60 negative cycles, being a total of 120 cycles. Read off the inductance in Henries by using the Inductance meter attached to the input side of the isolation transformer. Plot this value on the (nomographic) reactance chart. Plot the needed 120 Hz on the chart and connect these two points with a straight line. Where this line crosses the Farads line and the Ohms line, gives us two values. Choose one (resistor) and insert it between the two leads of the transformer input winding.

The Power Correction Factor Capacitor (or bank of more than one capacitor) now needs adjusting. The following formula is helpful in finding this missing information. The capacitance is known, as is the desired potential to pulse the output transformer. One Farad of capacitance is one volt for one second (one Coulomb). Therefore, if we want to keep the bucket full with a certain amount, how many dippers full are needed? If the bucket needs 120 volts, then how many coulombs are required?

$$\frac{\text{Desired Voltage}}{\text{Capacitance in Microfarads}} = \text{Required frequency in Hz}$$

Now, go to the nomograph mentioned above, and find the required resistor jumper to place between the poles of the Correction Factor Capacitor.

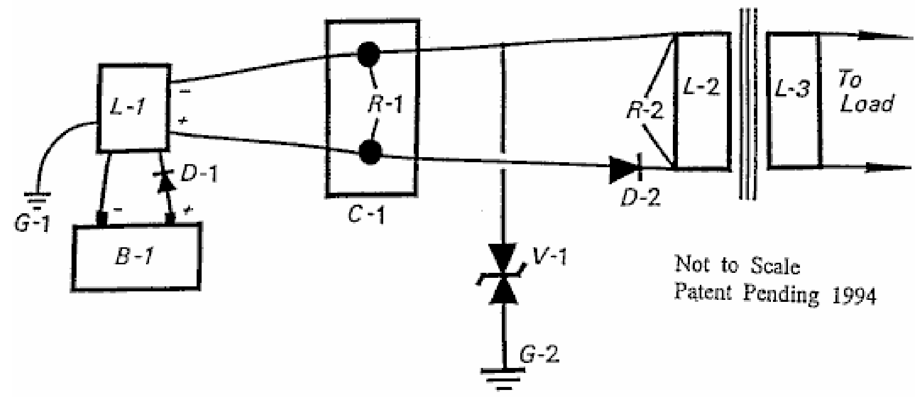
An earth grounding is desirable, acting as both a voltage-limiter and a transient spike control. Two separate earths are necessary, one at the Power Factor Capacitor and one at the input side of the isolation transformer. Off-the-shelf surge arrestors / spark gaps and varistors having the desired voltage/potential and amperage control are commonly available. Siemens, Citel America and others, make a full range of surge arrestors, etc. Varistors look like coin-sized flat capacitors. Any of these voltage limiters are marked as "V - 1" in the following text.

It should be obvious that several separate closed circuits are present in the suggested configuration: The power input source, the high-voltage module, a power factor capacitor bank combined with the input side of the isolation transformer. Lastly, the output side of the isolation transformer and its load. None of the electrons active at the power source (battery) are passed through the system for use downstream. At any point, if the magnetic flux rate should happen to vary, then the number of active electrons also varies. Therefore, controlling the flux rate controls the electron (potential) activity. Electrons active at point "A" are not the same electrons which are active at point "B", or those at point "C", and so on. If the magnetic flux rate (frequency Hz) varies, then a different number of electrons will be disturbed. This does not violate any Natural Law and it does produce more output energy than the input energy, should that be desirable.

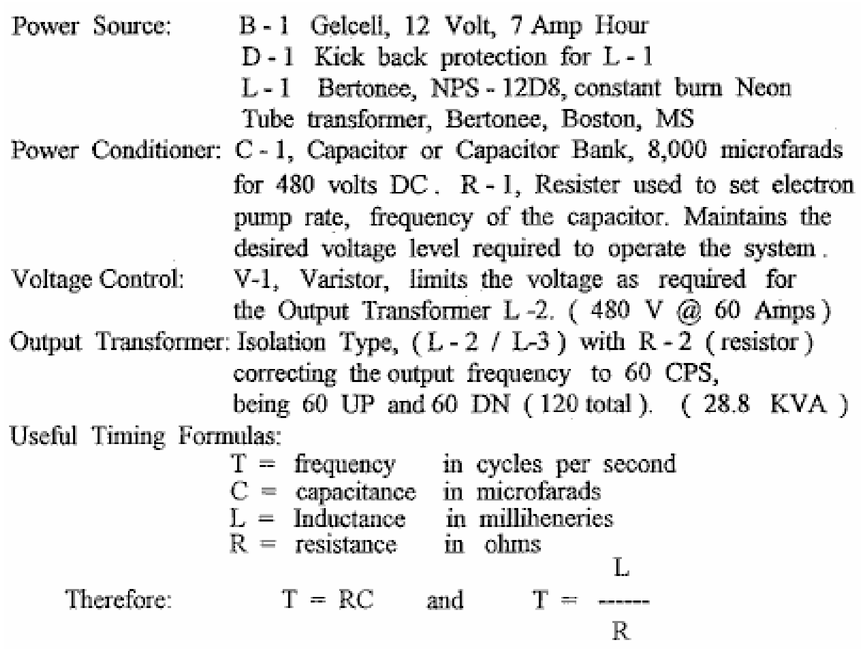
A convenient high-voltage module is a 12 volt DC neon tube transformer. The Power Factor Correction Capacitors should be as many microfarads as possible as this allows a lower operating frequency. The 12-volt neon tube transformer oscillates at about 30,000 Hz. At the Power Correction Factor Capacitor bank we lower the frequency to match the input side of the isolation transformer.

Other convenient high-voltage sources are car ignition coils, television flyback transformers, laser printer modules, and various other devices. Always lower the frequency at the Power Factor Correction Capacitor and correct, if needed, at the input side of the isolation transformer. The isolation transformer comes alive when pulsed. Amperage becomes a part of the consideration only at the isolation transformer. Faulty design, resulting in hysteresis, creates heat which self-destructs the transformer if it is overloaded. Transformers which have a composite core instead of the more common cores made from many layers of thin sheets of soft iron, run cool and can tolerate much higher amperage.

RESONATE ELECTROMAGNETIC POWER SYSTEM



Not to Scale
Patent Pending 1994



Power Source: B - 1 Gelcell, 12 Volt, 7 Amp Hour
D - 1 Kick back protection for L - 1
L - 1 Bertonee, NPS - 12D8, constant burn Neon Tube transformer, Bertonee, Boston, MS

Power Conditioner: C - 1, Capacitor or Capacitor Bank, 8,000 microfarads for 480 volts DC . R - 1, Resister used to set electron pump rate, frequency of the capacitor. Maintains the desired voltage level required to operate the system .

Voltage Control: V-1, Varistor, limits the voltage as required for the Output Transformer L -2. (480 V @ 60 Amps)

Output Transformer: Isolation Type, (L - 2 / L-3) with R - 2 (resistor) correcting the output frequency to 60 CPS, being 60 UP and 60 DN (120 total). (28.8 KVA)

Useful Timing Formulas:

T = frequency in cycles per second
C = capacitance in microfarads
L = Inductance in milliheneries
R = resistance in ohms

Therefore: $T = RC$ and $T = \frac{L}{R}$

The information shown above, relates to the small Suitcase Model demonstrated at the 1996 Tesla Convention, presented as Don Smiths' Workshop. This unit was a very primitive version and newer versions have atomic batteries and power output ranges of Gigawatts. The battery requirement is low level and is no more harmful than the radium on the dial of a clock. Commercial units of Boulder Dam size are currently being installed at several major locations throughout the world. For reasons of Don's personal security and contract obligations, the information which he has shared here, is incomplete.

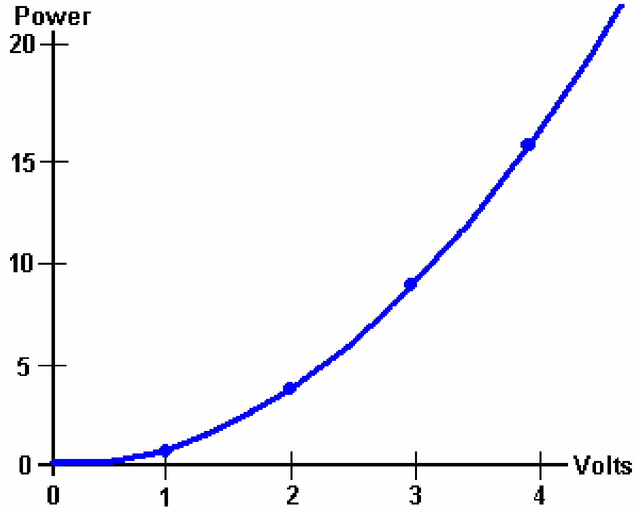
I am most definitely not an expert in this area. However, it is probably worth mentioning some of the main points which Don Smith appears to be making. There are some very important points being made here, and grasping these may make a considerable difference to our ability to tap into the excess energy available in our local environment. There are four points worth mentioning:

1. Voltage
2. Frequency
3. Magnetic / Electric relationship
4. Resonance

1. Voltage. We tend to view things with an 'intuitive' view, generally based on fairly simple concepts. For example, we automatically think that it is more difficult to pick up a heavy object than to pick up a light one. How much more difficult? Well, if it is twice as heavy, it would probably be about twice as much effort to pick it up. This view has developed from our experience of things which we have done in the past, rather than on any mathematical calculation or formula.

Well, how about pulsing an electronic system with a voltage? How would the output power of a system be affected by increasing the voltage? Our initial 'off-the cuff' reaction might be that the power output might be increased a bit, but then hold on… we've just remembered that Watts = Volts x Amps, so if you double the voltage, then you would double the power in watts. So we might settle for the notion that if we doubled the voltage then we could double the output power. If we thought that, then we would be wrong.

Don Smith points out that as capacitors and coils store energy, if they are involved in the circuit, then the output power is proportional to the **square** of the voltage used. Double the voltage, and the output power is four times greater. Use three times the voltage and the output power is nine times greater. Use ten times the voltage and the output power is one hundred times greater !



Don says that the energy stored, multiplied by the cycles per second, is the energy being pumped by the system. Capacitors and inductors (coils) temporarily store electrons, and their performance is given by:

Capacitor formula: $\mathbf{W = 0.5 \times C \times V^2 \times Hz}$ where:

W is the energy in Joules (Joules = Volts x Amps x seconds)
C is the capacitance in Farads
V is the voltage
Hz is the cycles per second

Inductor formula: $\mathbf{W = 0.5 \times L \times A^2 \times Hz}$ where:

W is the energy in Joules
L is the inductance in henrys
A is the current in amps
Hz is the frequency in cycles per second

You will notice that where inductors (coils) are involved, then the output power goes up with the square of the current. Double the voltage **and** double the current gives four times the power output due to the increased voltage and that increased output is increased by a further four times due to the increased current, giving sixteen times the output power.

2. Frequency. You will notice from the formulas above, that the output power is directly proportional to the frequency "Hz". The frequency is the number of cycles per second (or pulses per second) applied to the circuit. This is something which is not intuitive for most people. If you double the rate of pulsing, then you double the power output. When this sinks in, you suddenly see why Nikola Tesla tended to use millions of volts and millions of pulses per second.

However, Don Smith states that when a circuit is at it's point of resonance, resistance in the circuit drops to zero and the circuit becomes effectively, a superconductor. The energy for such a system which is in resonance is:

Resonant circuit: $\mathbf{W = 0.5 \times C \times V^2 \times (Hz)^2}$ where:

W is the energy in Joules
C is the capacitance in Farads
V is the voltage
Hz is the cycles per second

If this is correct, then raising the frequency in a resonating circuit has a massive effect on the power output of the device. The question then arises: why is the mains power in Europe just fifty cycles per second and in America just sixty cycles per second? If power goes up with frequency, then why not feed households at a million cycles per second? One major reason is that it is not easy to make electric motors which can be driven with power delivered at that frequency, so a more suitable frequency is chosen in order to suit the motors in vacuum cleaners, washing machines and other household equipment.

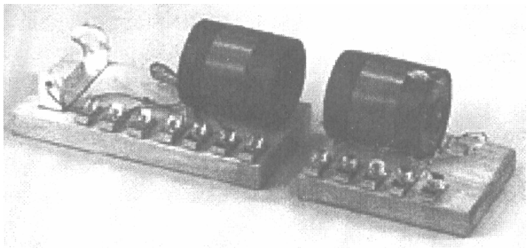
However, if we want to extract energy from the environment, then we should go for high voltage and high frequency. Then, when high power has been extracted, if we want a low frequency suited to electric motors, we can pulse the already captured power at that low frequency.

It might be speculated that if a device is being driven with sharp pulses which have a very sharply rising leading edge, that the effective frequency of the pulsing is actually determined by the speed of that rising edge, rather than the rate at which the pulses are actually generated. For example, if pulses are being generated at, say, 50 kHz but the pulses have a leading edge which would be suited to a 200 kHz pulse train, then the device might well see the signal as a 200 kHz signal with a 25% Mark/Space ratio, the very suddenness of the applied voltage having a magnetic shocking effect equivalent to a 200 kHz pulse train.

3. Magnetic / Electric relationship. Don states that the reason why our present power systems are so inefficient is because we concentrate on the electric component of electromagnetism. These systems are always COP<1 as electricity is the 'losses' of electromagnetic power. Instead, if you concentrate on the magnetic component, then there is no limit on the electric power which can be extracted from that magnetic component. Contrary to what you might expect, if you install a pick-up system which extracts electrical energy from the magnetic component, you can install any number of other identical pick-ups, each of which extract the same amount of electrical energy from the magnetic input, **without** loading the magnetic wave in any way. Unlimited electrical output for the 'cost' of creating a single magnetic effect.

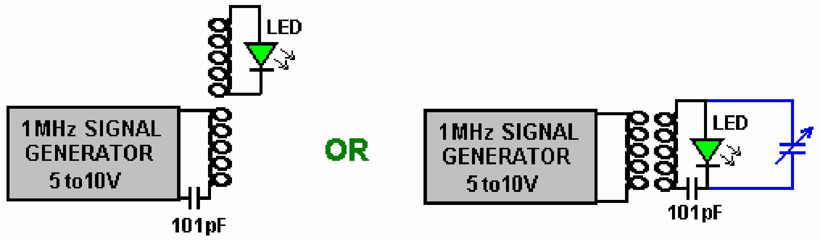
The magnetic effect which we want to create is a ripple in the zero-point energy field, and ideally, we want to create that effect while using very little power. Creating a dipole with a battery which has a Plus and a Minus terminal or a magnet which has North and South poles, is an easy way to do create an electromagnetic imbalance in the local environment. Pulsing a coil is probably an even better way as the magnetic field reverses rapidly if it is an air-core coil, such as a Tesla Coil. Using a ferromagnetic core to the coil can create a problem as iron can't reverse it's magnetic alignment very rapidly, and ideally, you want pulsing which is at least a thousand times faster than iron can handle.

Don draws attention to the "Transmitter / Receiver" educational kit "Resonant Circuits #10-416" supplied by The Science Source, Maine. This kit demonstrates the generation of resonant energy and it's collection with a receiver circuit. However, if several receiver circuits are used, then the energy collected is increased several times without any increase in the transmitted energy. This is similar to a radio transmitter where hundreds of thousands of radio receivers can receive the transmitted signal without loading the transmitter in any way.



If you get the Science Source educational kit, then there are some details which you need to watch out for. The unit supplied to me had two very nice quality plastic bases and two very neatly wound coils each of 60 turns of 0.47 mm diameter enamelled copper wire on clear acrylic tubes 57 mm (2.25") in diameter. The winding covers a 28 mm section of the tube. The layout of the transmitter and receiver modules does not match the accompanying instruction sheet and so considerable care needs to be taken when wiring up any of their circuits.

The circuit diagrams are not shown, just a wiring diagram, which is not great from an educational point of view. The one relevant circuit is:

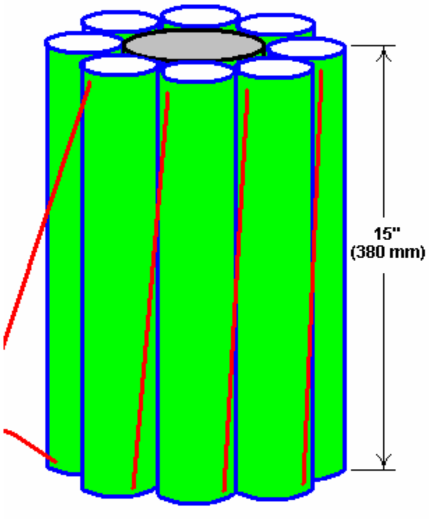


Before you buy the kit, it is not mentioned that in order to use it, you need a signal generator capable of producing a 10-volt signal at 1 MHz. The coil has a DC resistance of just 1.9 ohms but at a 1 MHz resonant frequency, the necessary drive power is quite low.

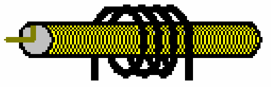
A variable capacitor is mounted on the receiver coil tube, but the one in my kit made absolutely no difference to the frequency tuning, nor was my capacitance meter able to determine any capacitance value for it at all, even though it had no trouble at all in measuring the 101 pF capacitor which was exactly the capacitance printed on it. For that reason, it is shown in blue in the circuit diagram above. Disconnecting it made no difference whatsoever.

In this particular kit, standard screw connectors have had one screw replaced with an Allen key headed bolt which has a head large enough to allow finger tightening. Unfortunately, those bolts have a square cut head where a domed head is essential if small diameter wires are to be clamped securely. If you get the kit, then I suggest that you replace the connectors with a standard electrical screw connector strip.

In tests, the LED lights when the coils are aligned and within about 100 mm of each other, or if they are close together side by side. This immediately makes the Hubbard device spring to mind. Hubbard has a central "electromagnetic transmitter" surrounded by a ring of "receivers" closely coupled magnetically to the transmitter, each of which will receive a copy of the energy sent by the transmitter:

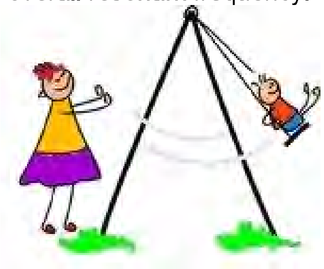


Don points to an even more clearly demonstrated occurrence of this effect in the Tesla Coil. In a typical Tesla Coil, the primary coil is much larger diameter than the inner secondary coil:



If, for example, 8,000 volts is applied to the primary coil which has four turns, then each turn would have 2,000 volts of potential. Each turn of the primary coil transfers electromagnetic flux to every single turn of the secondary winding, and the secondary coil has a very large number of turns. Massively more power is produced in the secondary coil than was used to energise the primary coil. A common mistake is to believe that a Tesla Coil can't produce serious amperage. If the primary coil is positioned in the middle of the secondary coil as shown, then the amperage generated will be as large as the voltage generated. A low power input to the primary coil can produce kilowatts of usable electrical power as described in chapter 5.

4. Resonance. An important factor in circuits aimed at tapping external energy is resonance. It can be hard to see where this comes in when it is an electronic circuit which is being considered. However, everything has it's own resonant frequency, whether it is a coil or any other electronic component. When components are connected together to form a circuit, the circuit has an overall resonant frequency. As a simple example, consider a swing:



If the swing is pushed before it reaches the highest point on the mother's side, then the push actually detracts from the swinging action. The time of one full swing is the resonant frequency of the swing, and that is determined by the length of the supporting ropes holding the seat and not the weight of the child nor the power with which the child is pushed. Provided that the timing is exactly right, a very small push can get a swing moving in a substantial arc. The key factor is, matching the pulses applied to the swing, to the resonant frequency of the swing. Get it right and a large movement is produced. Get it wrong, and the swing doesn't get going at all (at which point, critics would say "see, see …swings just don't work - this proves it !!").

Establishing the exact pulsing rate needed for a resonant circuit is not particularly easy, because the circuit contains coils (which have inductance, capacitance and resistance), capacitors (which have capacitance and a small amount of resistance) and resistors and wires, both of which have resistance and some capacitance. These kinds of circuit are called "LRC" circuits because "L" is the symbol used for inductance, "R" is the symbol used for resistance and "C" is the symbol used for capacitance.

Don Smith provides instructions for winding and using the type of air-core coils needed for a Tesla Coil. He says:

1. Decide a frequency and bear in mind, the economy of the size of construction selected. The factors are:

(a) Use radio frequency (above 20 kHz).
(b) Use natural frequency, i.e. match the coil wire length to the frequency - coils have both capacitance and inductance.
(c) Make the wire length either one quarter, one half of the full wavelength.
(d) Calculate the wire length in feet as follows:
    If using one quarter wavelength, then divide 247 by the frequency in MHz.
    If using one half wavelength, then divide 494 by the frequency in MHz.
    If using the full wavelength, then divide 998 by the frequency in MHz.
  For wire lengths in metres:
    If using one quarter wavelength, then divide 75.29 by the frequency in MHz.
    If using one half wavelength, then divide 150.57 by the frequency in MHz.
    If using the full wavelength, then divide 304.19 by the frequency in MHz.

2. Choose the number of turns to be used in the coil when winding it using the wire length just calculated. The number of turns will be governed by the diameter of the tube on which the coil is to be wound. Remember that the ratio of the number of turns in the "L - 1" and "L - 2" coils, controls the overall output voltage. For example, if the voltage applied the large outer coil "L - 1" is 2,400 volts and L - 1 has ten turns, then each turn of L - 1 will have 240 volts dropped across it. This 240 volts of magnetic induction transfers 240 volts of electricity to every turn of wire in the inner "L - 2" coil. If the diameter of L - 2 is small enough to have 100 turns, then the voltage produced will be 24,000 volts. If the diameter of the L - 2 former allows 500 turns, then the output voltage will be 120,000 volts.

3. Choose the length and diameter of the coils. The larger the diameter of the coil, the fewer turns can be made with the wire length and so the coil length will be less, and the output voltage will be lower.

4. For example, if 24.7 MHz is the desired output frequency, then the length of wire, in feet, would be 247 divided by 24.7 which is 10 feet of wire (3,048 mm). The coil may be wound on a standard size of PVC pipe or alternatively, it can be purchased from a supplier - typically, an amateur radio supply store.

If the voltage on each turn of L - 1 is arranged to be 24 volts and the desired output voltage 640 volts, then there needs to be 640 / 24 = 26.66 turns on L - 2, wound with the 10 feet of wire already calculated.

Note: At this point, Don's calculations go adrift and he suggests winding 30 turns on a 2-inch former. If you do that, then it will take about 16 feet of wire and the resonant point at 10-feet will be at about 19 turns, giving an output voltage of 458 volts instead of the required 640 volts, unless the number of turns on L - 1 is reduced to give more than 24 volts per turn. However, the actual required diameter of the coil former (plus one diameter of the wire) is 10 x 12 / (26.67 x 3.14159) = 1.43 inches. You can make this size of former up quite easily if you want to stay with ten turns on the L - 1 coil.

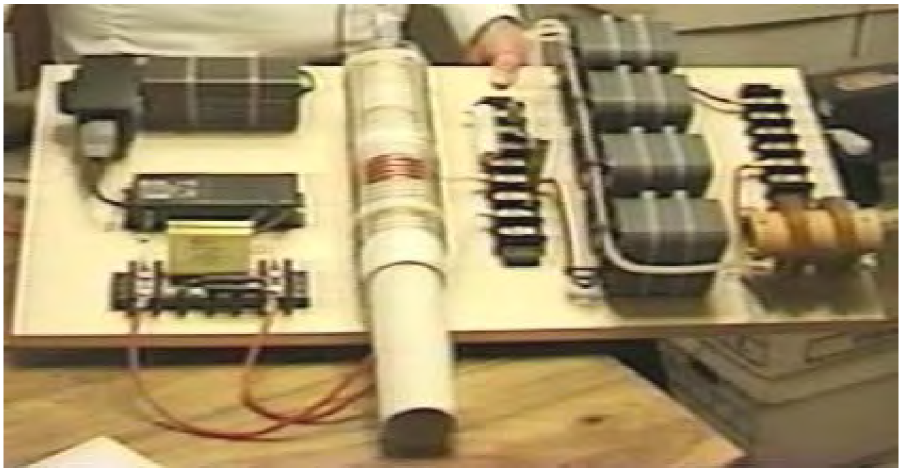
5. Connect to the start of the coil. To determine the exact resonant point on the coil, a measurement is made. Off-the-shelf multimeters are not responsive to high-frequency signals so a cheap neon is used instead. Holding one wire of the neon in one hand and running the other neon wire along the outside of the L - 2 winding, the point of brightest light is located. Then the neon is moved along that turn to find the brightest point along that turn, and when it is located, a connection is made to the winding at that exact point. L - 2 is now a resonant winding. It is possible to increase the ("Q") effectiveness of the coil by spreading the turns out a bit instead of positioning them so that each turn touches both of the adjacent turns.

6. The input power has been suggested as 2,400 volts. This can be constructed from a Jacob's ladder arrangement or any step-up voltage system. An off-the-shelf module as used with lasers is another option.

7. Construction of the L - 1 input coil has been suggested as having 10 turns. The length of the wire in this coil is not critical. If a 2-inch diameter PVC pipe was used for the L - 2 coil, then the next larger size of PVC pipe can be used for the L - 1 coil former. Cut a 10-turn length of the pipe (probably a 3-inch diameter pipe). The pipe length will depend on the diameter of the insulated wire used to make the winding. Use a good quality multimeter or a specialised LCR meter to measure the capacitance (in Farads) and the inductance (in henrys) of the L - 2 coil. Now, put a capacitor for matching L - 1 to L - 2 across the voltage input of L - 1, and a spark gap connected **in parallel** is required for the return voltage from L - 1. A trimmer capacitor for L - 1 is desirable.

8. The performance of L - 2 can be further enhanced by attaching an earth connection to the base of the coil. The maximum output voltage will be between the ends of coil L - 2 and lesser voltages can be taken off intermediate points along the coil if that is desirable.

Don provides quite an amount of information on one of his devices shown here:



I have recently been passed a copy of Don's circuit diagram for this device, and it is shown here:

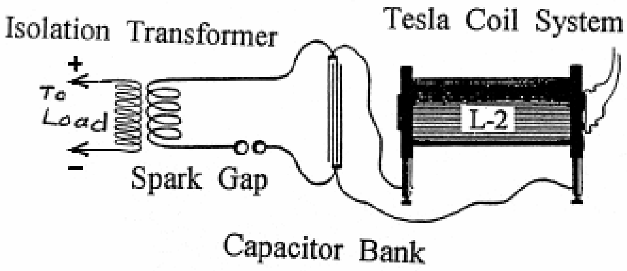
This circuit diagram contradicts what Don says in his video presentations as the output matches the photographs which show the four output capacitors wired in parallel. It appears that while using the prototype shown above as an example of the construction, in the videos Don is actually describing a later version of the circuit. The 4000V

30mA transformer shown in this circuit diagram, is a neon-tube driver module which steps up the voltage and raises the frequency to about 35 kilohertz.

There is always a tendency to think of a spark gap as being a device which is there to protect against excessive voltages rather than seeing it as an active component of the circuit, a component which is in continuous use as it is in this circuit. Tesla, who always speaks very highly of the energy released by the very sharp discharge produced by a spark, shows a high-voltage source feeding a capacitor with the energy passing through a spark gap to the primary winding of a transformer:



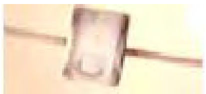
With Don's arrangement, it can be a little difficult to see why the capacitor is not short-circuited by the very low resistance of the few turns of thick wire forming the L1 coil. Well, it would do that if we were operating with DC, but we are most definitely not doing that as the output from the neon-tube driver circuit is pulsing 35,000 times per second. This causes the DC resistance of the L1 coil to be of almost no consequence and instead, the coil's AC "impedance" (effectively, it's AC resistance) is what counts. Actually, the “C1” capacitor and the L1 coil being connected across each other have a combined "impedance" or resistance to pulsing current at this frequency. This is where the nomograph diagram comes into play, and there is a much easier to understand version of it a few pages later on in this document. So, because of the high pulsing frequency, the L1 coil does not short-circuit the capacitor and if the pulsing frequency matches the resonant frequency of the L1 coil (or a harmonic of that frequency), then the L1 coil will actually have a very high resistance to current flow through it. This is how a crystal set radio receiver tunes in a particular radio station, broadcasting on it's own frequency.

Anyway, coming back to Don's device shown in the photograph above, the electrical drive is from a 12-volt battery which is not seen in the photograph. Interestingly, Don remarks that if the length of the wires connecting the battery to the inverter are exactly one quarter of the wave length of the frequency of the oscillating magnetic field generated by the circuit, then the current induced in the battery wires will recharge the battery continuously, even if the battery is supplying power to the circuit at the same time.

The battery supplies a small current through a protecting diode, to a standard off-the-shelf "true sine-wave" inverter. An inverter is a device which produces mains-voltage Alternating Current from a DC battery. As Don wants adjustable voltage, he feeds the output from the inverter into a variable transformer called a "Variac" although this is often made as part of the neon-driver circuit to allow the brightness of the neon tube to be adjusted by the user. This arrangement produces an AC output voltage which is adjustable from zero volts up to the full mains voltage (or a little higher, although Don does not want to use a higher voltage). The use of this kind of adjustment usually makes it essential for the inverter to be a true sine-wave type. As the power requirement of the neon-tube driver circuit is so low, the inverter should not cost very much and Don specifies just 140 watts of continuous current for the inverter specification.

The neon-tube (or "gas-discharge" tube) driver circuit is a standard off-the-shelf device used to drive neon tube displays for commercial establishments. The one used by Don contains an oscillator and a step-up transformer, which together produce an Alternating Current of 4,000 volts at a frequency of 35,100 Hz (sometimes written as 35.1 kHz). The term "Hz" stands for "cycles per second". It should be noted, however, that since Don bought his neon-tube driver module, the design of many of those modules has been altered to include protection circuitry which is liable to prevent the module operating properly in this circuit. It might be worth considering building your own solid-state circuit as shown later on in this chapter. If you do that, then you have full control of the frequency and the output and are not dependent on anyone else’s circuit design.

In this circuit, Don lowers the 4,000 volts as he gets great power output at lower input voltages and the cost of the output capacitors is a significant factor. The particular neon-tube driver circuit which Don is using here, has two separate outputs, so Don connects them together and uses a blocking diode in each line to prevent either of them affecting the other one. Not easily seen in the photograph, the high-voltage output line has a very small, encapsulated, spark gap in it and the line is also earthed. This device is commonly used as a lightning strike protection component but it is an active component in Don's circuit and it lights continuously when the device is running. It looks like this:

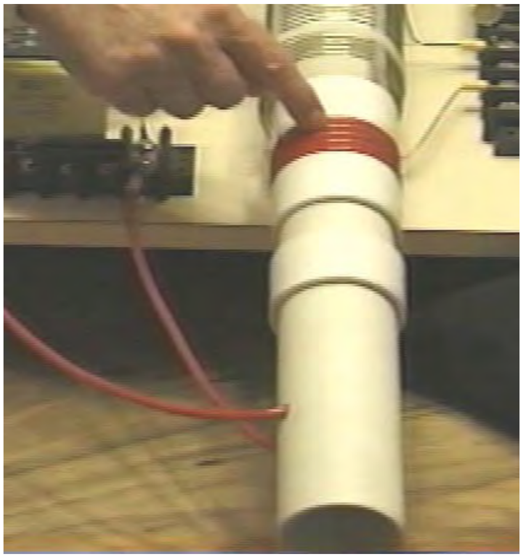


Please note that when an earth connection is mentioned in connection with Don Smith's devices, we are talking about an actual wire connection to a metal object physically buried in the ground, whether it is a long copper rod driven into the ground, or an old car radiator buried in a hold like Tariel Kapanadze uses, or a buried metal plate. When Thomas Henry Moray performed his requested demonstration deep in the countryside at a location chosen by the sceptics, the light bulbs which formed his demonstration electrical load, glowed more brightly with each hammer stroke as a length of gas pipe was hammered into the ground to form his earth connection.

The output of the neon-tube driver circuit is used to drive the primary "L1" winding of a Tesla Coil style transformer. This looks ever so simple and straightforward, but there are some subtle details which need to have attention paid to them.

The operating frequency of 35.1 kHz is set and maintained by the neon-tube driver circuitry, and so, in theory, we do not have to do any direct tuning ourselves. However, we want the resonant frequency of the L1 coil and the capacitor across it to match the neon-driver circuit frequency. The frequency of the "L1" coil winding will induce exactly the same frequency in the "L2" secondary winding with the “C6” tuning capacitor across it. However, we need to pay special attention to the ratio of the wire lengths of the two coil windings as we want these two windings to resonate together.

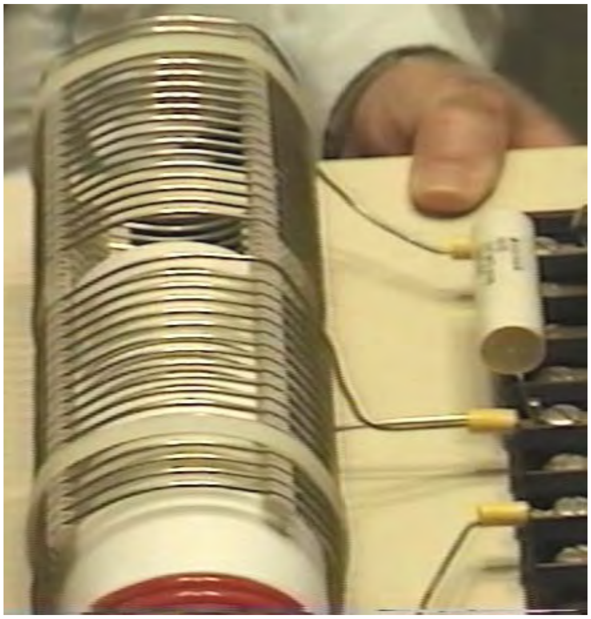
A rule of thumb followed by most Tesla Coil builders is to have the same weight of copper in the L1 and L2 coils, which means that the wire of the L1 coil is usually much thicker than the wire of the L2 coil. If the L1 coil is to be one quarter of the length of the L2 coil, then we would expect the cross-sectional area of the L1 coil to be four times that of the wire of the L2 coil (as the area is proportional to the square of the radius, and the square of two is four, so doubling the wire diameter gives four times the cross-sectional area of the copper wire).



Don uses a plastic tube as the former for his "L1" primary coil winding. As you can see here, the wire is fed into the former, leaving sufficient clearance to allow the former to slide all the way into the outer coil. The wire is fed up inside the pipe and out through another hole to allow the coil turns to be made on the outside of the pipe. There appear to be five turns, but Don does not always go for a complete number of turns, so it might be 4.3 turns or some other value. The key point here is that the length of wire in the "L1" coil turns should be exactly one quarter of the length of wire in the "L2" coil turns.

The "L2" coil used here is a commercial 3-inch diameter unit from Barker & Williamson, constructed from uninsulated, solid, single-strand "tinned" copper wire. Don has taken this coil and unwound four turns at the centre of the coil in order to make a centre-tap. He then measured the exact length of wire in the remaining section and made the length of the "L1" coil turns to be exactly one quarter of that length. The wire used for the "L1" coil looks like Don's favourite "Jumbo Speaker Wire" which is a very flexible wire with a very large number of extremely fine uninsulated copper wires inside it.

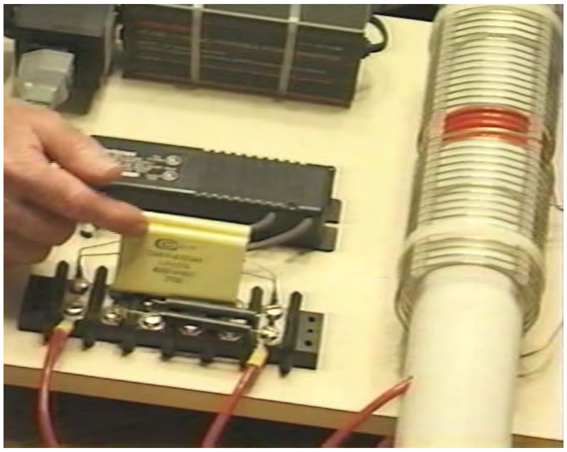
You will notice that Don has placed a plastic collar on each side of the winding, matching the thickness of the wire, in order to create a secure sliding operation inside the outer "L2" coil, and the additional plastic collars positioned further along the pipe provide further support for the inner coil. This sliding action allows the primary coil "L1" to be positioned at any point along the length of the "L2" secondary coil, and that has a marked tuning effect on the operation of the system. The outer "L2" coil does not have any kind of tube support but instead, the coil shape is maintained by the stiffness of the solid wire plus four slotted plastic strips. This style of construction produces a very high coil performance at radio frequencies. With a Tesla Coil, it is most unusual to have the L1 coil of smaller diameter than the L2 coil.



The "L2" coil has two separate sections, each of seventeen turns. One point to note is the turns are spaced apart using slotted strips to support the wires and maintain an accurate spacing between adjacent turns. It must be remembered that spacing coil turns apart like this alters the characteristics of the coil, increasing it's "capacitance" factor substantially. Every coil has resistance, inductance and capacitance, but the form of the coil construction has a major effect on the ratio of these three characteristics. The coil assembly is held in position on the base board by two off-white plastic cable ties.

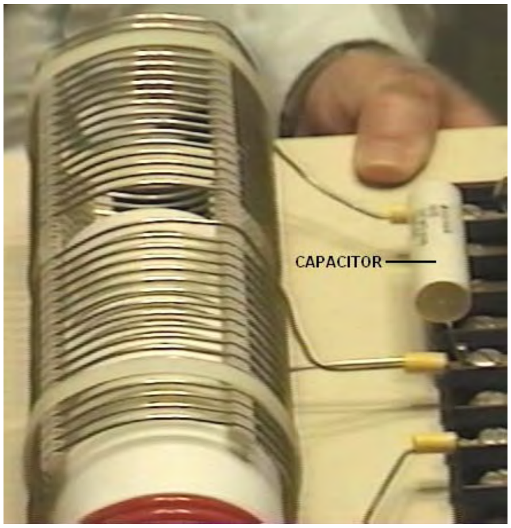
One point which Don stresses, is that the length of the wire in the "L1" coil and the length of wire in the "L2" coil, must be an exact even division or multiple of each other (in this case, the "L2" wire length in each half of the "L2" coil is exactly four times as long as the "L1" coil wire length). This is likely to cause the "L1" coil to have part of a turn, due to the different coil diameters. For example, if the length of the "L2" coil wire is 160 inches and "L1" is to be one quarter of that length, namely, 40 inches. Then, if the "L1" coil has an effective diameter of 2.25 inches, (allowing for the thickness of the wire when wound on a 2-inch diameter former), then the "L1" coil would have 5.65 (or 5 and 2/3) turns which causes the finishing turn of "L2" to be 240 degrees further around the coil former than the start of the first turn - that is, five full turns plus two thirds of the sixth turn.

The L1 / L2 coil arrangement is a Tesla Coil. The positioning of the "L1" coil along the length of the "L2" coil, adjusts the voltage to current ratio produced by the coil. When the "L1" coil is near the middle of the "L2" coil, then the amplified voltage and amplified current are roughly the same. However, Don stresses that the "height" length of the coil (when standing vertically) controls the voltage produced while the coil "width" (the diameter of the turns) controls the current produced.



The exact wire length ratio of the turns in the "L1" and "L2" coils gives them an almost automatic synchronous tuning with each other, and the exact resonance between them can be achieved by the positioning of the "L1" coil along the length of the "L2" coil.

Don has also connected a small capacitor across the "L2" coil, and that optional component is marked as "C2" in the circuit diagram and the value used by Don happened to be a single 47nF, high-voltage capacitor. As the two halves of the "L2" coil are effectively connected across each other, it is only necessary to have one capacitor for "L2":

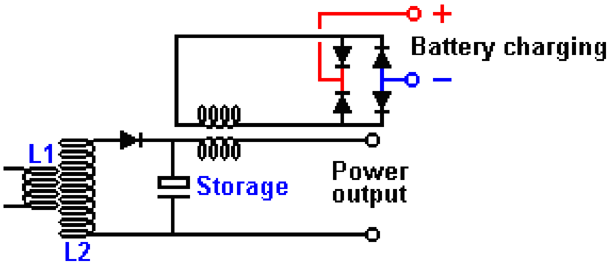


There are various ways of dealing with the output from the "L2" coil in order to get large amounts of conventional electrical power out of the device. The method shown here uses the four very large capacitors seen in the photograph. Don remarks that he has to be very careful to keep the voltage to the neon-tube driver circuit turned down in order to avoid getting more than 2,000 volts on these output storage capacitors.

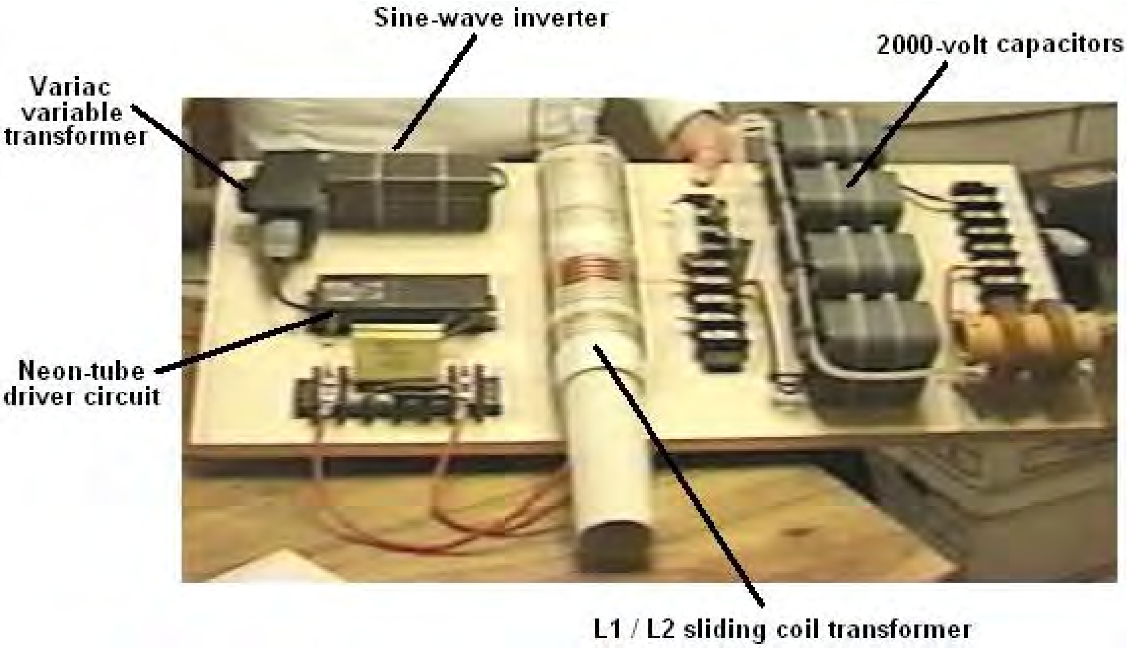
This capacitor bank is fed through two diodes which are rated for high voltage operation. In the build shown in the photographs and the circuit diagram, the output is rated at 2,000 volts and 6,000 watts, in which case, the output diodes have to be able to handle 3 amps continuously, but at start-up when the capacitor bank is fully discharged that current may well be exceeded while the capacitor bank charges up.

When the circuit is running, the storage capacitor bank behaves like a 2,000 volt battery which never runs down and which can supply 3 amps of current for as long as you want. The circuitry for producing a 220 volt 50 Hz AC output or a 110 volt 60 Hz AC output from the storage capacitors is just standard electronics.

The output current flows through the left hand winding on the brown cylindrical former, and that induces a current in the right-hand winding. This additional current is used to provide charging power for the battery used to drive the inverter. A possible circuit arrangement for doing this might be as shown here:



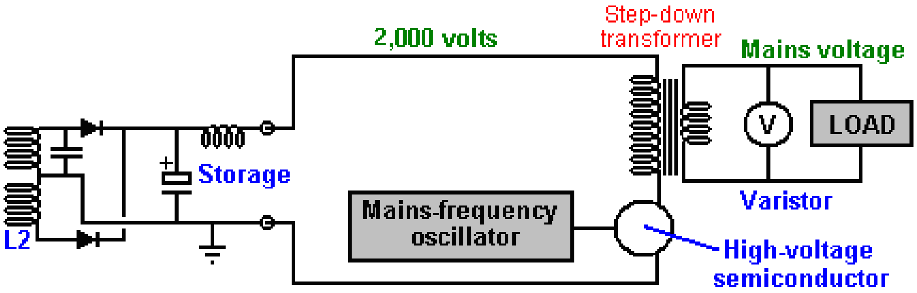
The DC output produced by the four diodes can then be used to charge the driving battery, and the power level produced is substantially greater than the minor current drain from the battery. Consequently, it is a sensible precaution to pass this current to the battery via a circuit which prevents the battery voltage rising higher than it should. A simple voltage level sensor can be used to switch off the charging when the battery has reached its optimum level. Other batteries can also be charged if that is wanted. Simple circuitry of the type shown in chapter 12 can be used for controlling and limiting the charging process. The components on Don's board are laid out like this:



Don draws attention to the fact that the cables used to connect the output of "L2" to the output of the board, connecting the storage capacitors on the way, are very high-voltage rated cables with special multiple coverings to ensure that the cables will remain sound over an indefinite period. It should be remarked at this point, that the outer 3" diameter coil used by Don, is not wound on a former, but in order to get higher performance at high frequencies, the turns are supported with four separate strips physically attached to the turns - the technique described later in this document as being an excellent way for home construction of such coils.

Please bear in mind that the voltages here and their associated power levels are literally lethal and perfectly capable of killing anyone who handles the device carelessly when it is powered up. When a replication of this device is ready for routine use, it must be encased so that none of the high-voltage connections can be touched by anyone. This is not a suggestion, but it is a mandatory requirement, despite the fact that the components shown in the photographs are laid out in what would be a most dangerous fashion were the circuit to be powered up as it stands. Under no circumstances, construct and test this circuit unless you are already experienced in the use of high-voltage circuits or can be supervised by somebody who is experienced in this field. This is a "one hand in the pocket at all times" type of circuit and it needs to be treated with great care and respect at all times, so be sensible.

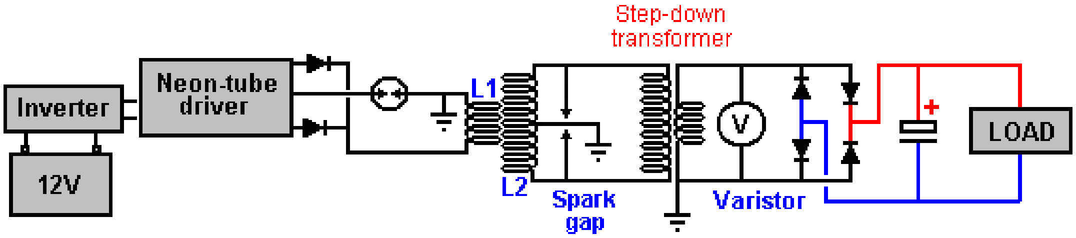
It may also be necessary to use an earthed screen around the device in order to prevent radio frequency emissions. The remainder of the circuit is not mounted on the board, possibly because there are various ways in which the required end result can be achieved. The one suggested here is perhaps the most simple solution:



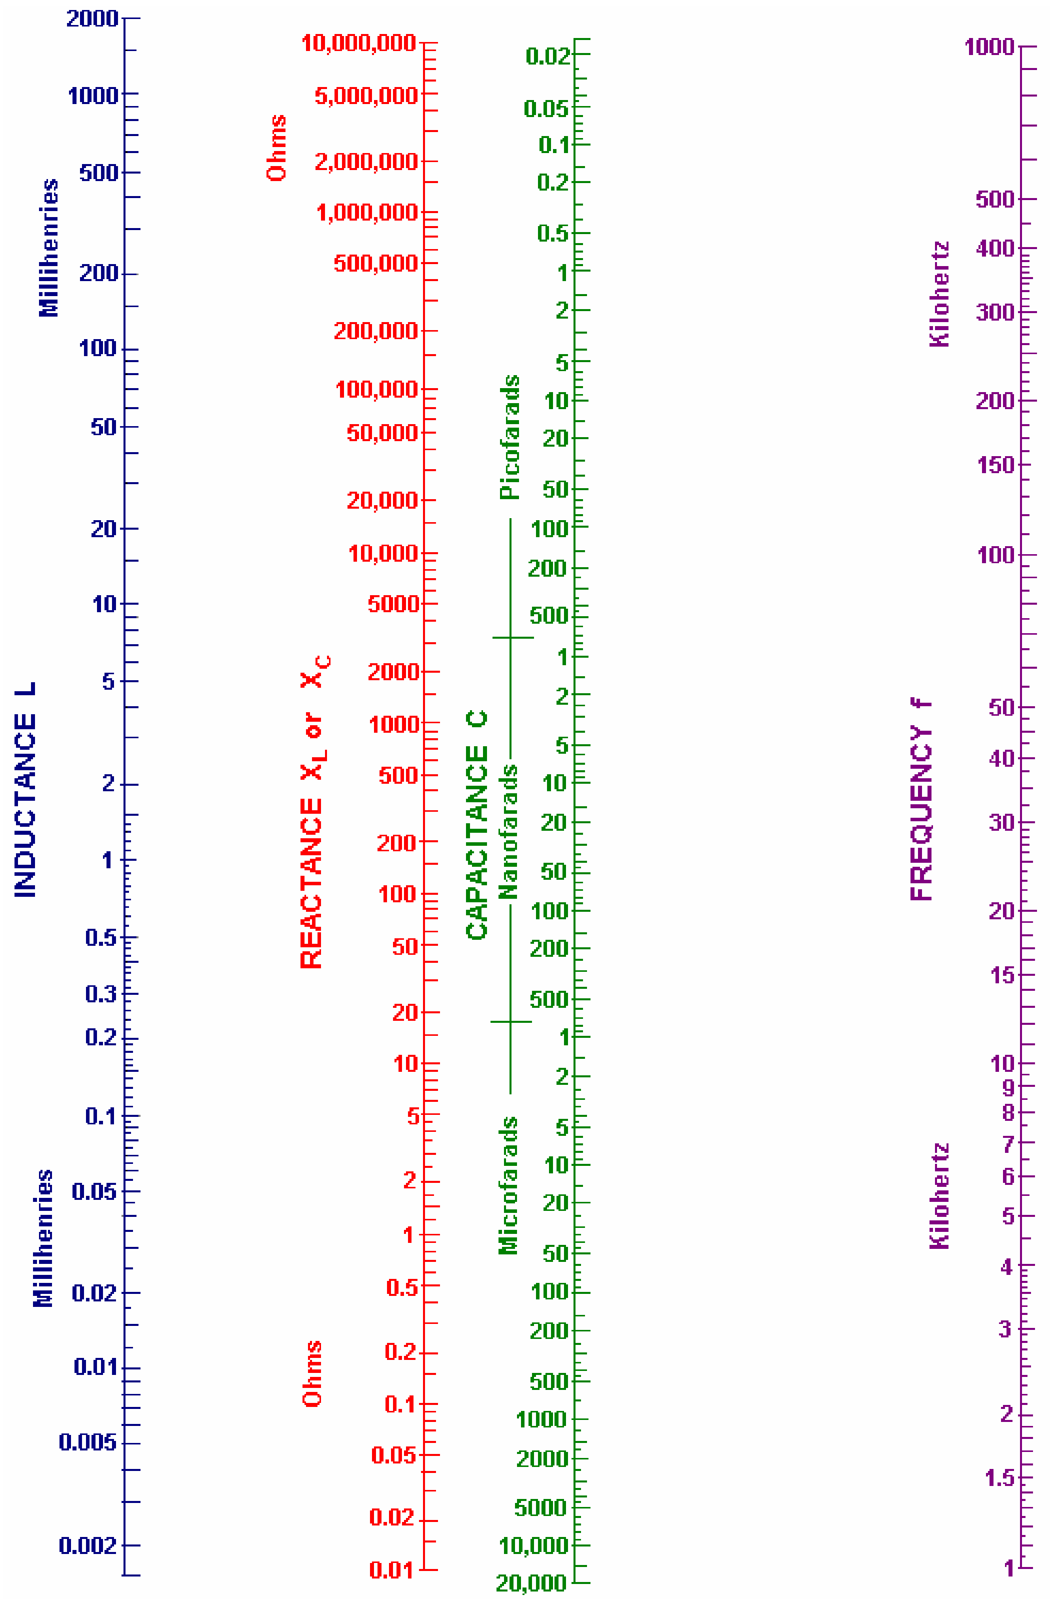
The voltage has to be dropped, so an iron-cored mains-frequency step-down transformer is used to do this. To get the frequency to the standard mains frequency for the country in which the device is to be used, an oscillator is used to generate that particular mains frequency. The oscillator output is used to drive a suitable high-voltage semiconductor device, be it an FET transistor, an IGBT device, or whatever. This device has to switch the working current at 2,000 volts, though admittedly, that will be a current which will be very much lower than the final output current, due to the higher voltage on the primary winding of the transformer. When using this circuit, the available power will be limited by the current handling capabilities of this output transformer, so a custom-wound unit with heavy-duty wire and a substantial frame will be needed to provide the full six kilowatts of power.

As the circuit is capable of picking up additional magnetic pulses, such as those generated by other equipment, nearby lightning strikes, etc. an electronic component called a "varistor" marked "V" in the diagram, is connected across the load. This device acts as a voltage spike suppressor as it short circuits any voltage above its design voltage, protecting the load from power surges.

Don also explains an even more simple version which does not need a Variac, high voltage capacitors or high voltage diodes. Here, a DC output is accepted which means that high-frequency step-down transformer operation can be used. This calls for an air-core transformer which you would wind yourself from heavy duty wire. Mains loads would then be powered by using a standard off-the-shelf inverter. In this version, it is of course, necessary to make the "L1" turns wire length exactly one quarter of the "L2" turns wire length in order to make the two coils resonate together. The operating frequency of each of these coils is imposed on them by the output frequency of the neon-tube driver circuit. That frequency is maintained throughout the entire circuit until it is rectified by the four diodes feeding the low-voltage storage capacitor. The target output voltage will be either just over 12 volts or just over 24 volts, depending on the voltage rating of the inverter which is to be driven by the system. This is effectively two Tesla Coils back-to-back and the circuit diagram might be:

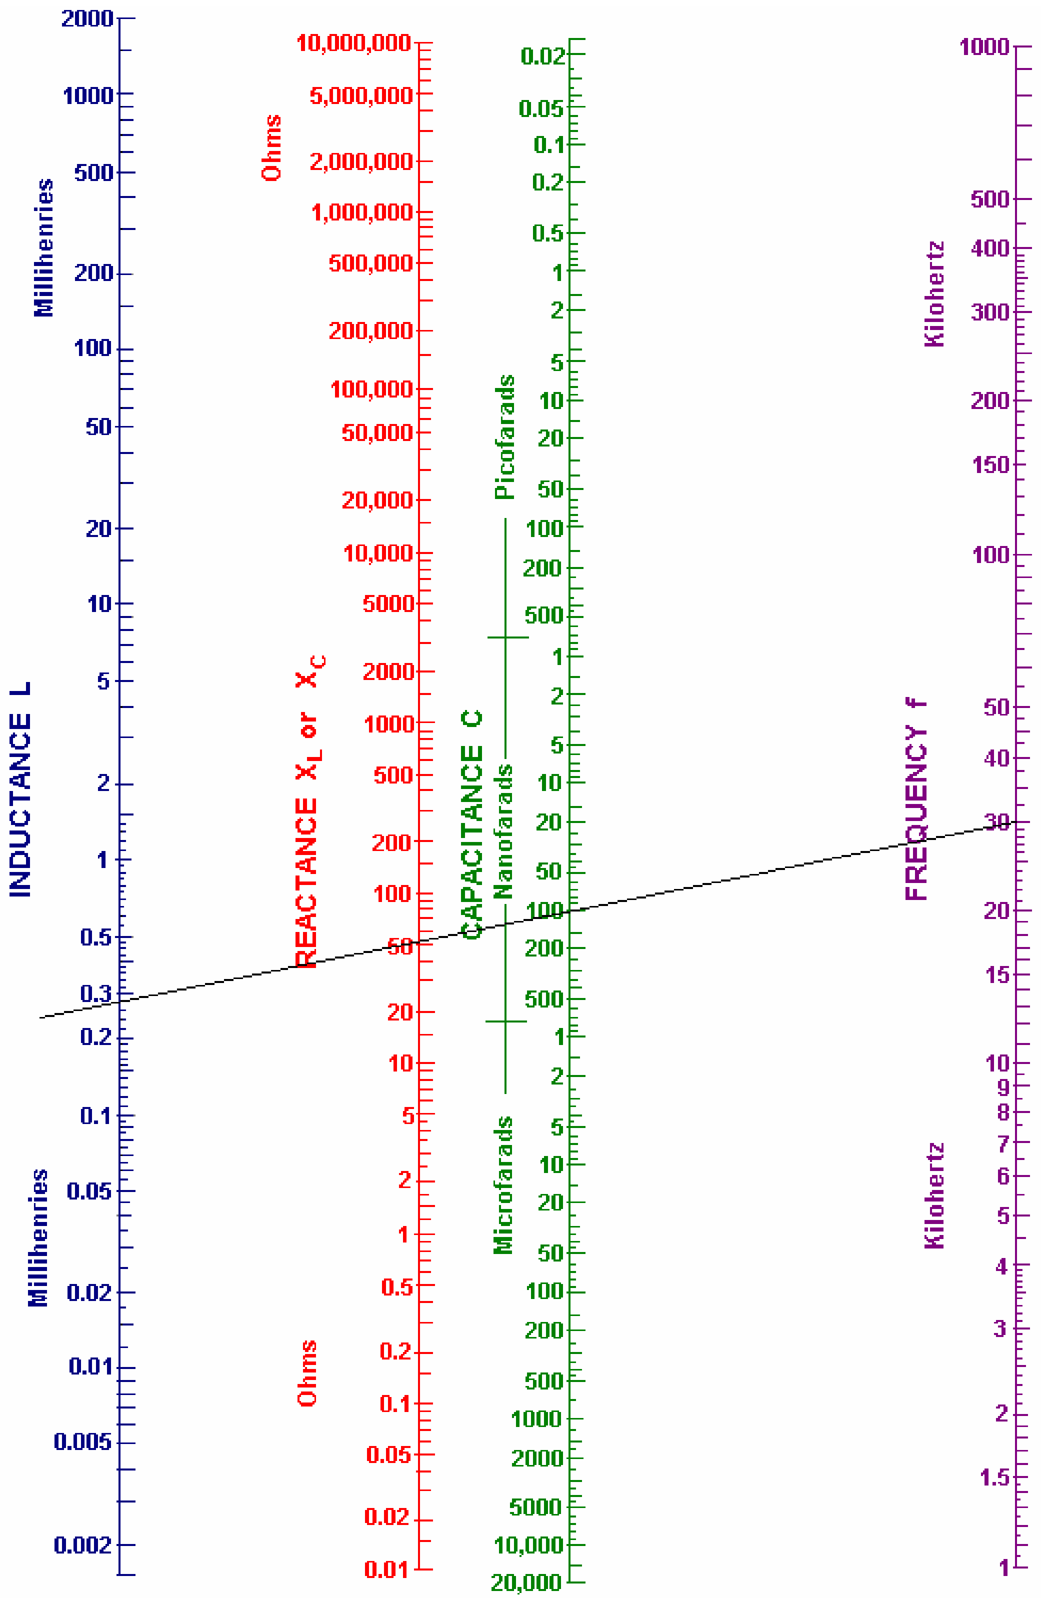


As many people will find the nomograph chart in Don's pdf document very difficult to understand and use, here is an easier version:



The objective here is to determine the "reactance" or 'AC resistance' in ohms and the way to do that is as follows:

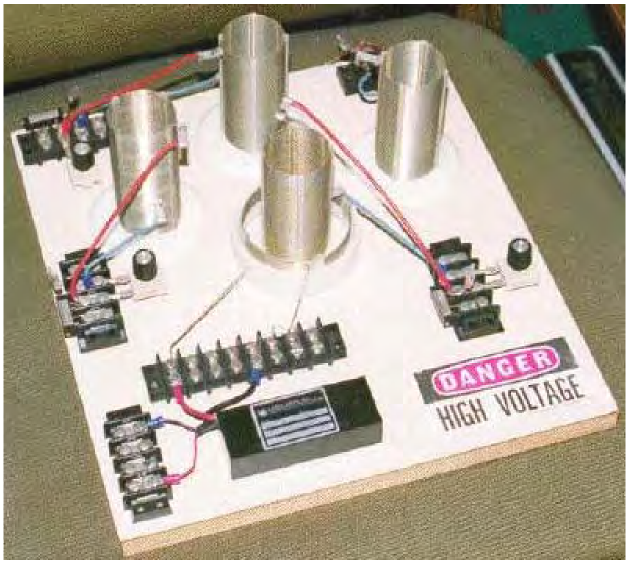
Suppose that your neon-tube driver is running at 30 kHz and you are using a capacitor of 100 nF (which is the same as 0.1 microfarad) and you want to know what is the AC resistance of your capacitor is at that frequency. Also, what coil inductance would have that same AC resistance. Then the procedure for finding that out is as follows:



Draw a straight line from your 30 kHz frequency (purple line) through your 100 nanofarad capacitor value and carry the line on as far as the (blue) inductance line as shown above.

You can now read the reactance off the red line, which looks like 51 ohms to me. This means that when the circuit is running at a frequency of 30 kHz, then the current flow through your 100 nF capacitor will be the same as through a 51 ohm resistor. Reading off the blue "Inductance" line that same current flow at that frequency would occur with a coil which has an inductance of 0.28 millihenries.

Another device of Don's is particularly attractive in that almost no home-construction is needed, all of the components being available commercially, and the output power being adaptable to any level which you want. Don particularly likes this circuit because it demonstrates COP>1 so neatly and he remarks that the central transmitter Tesla Coil on its own is sufficient to power a household.



The coil in the centre of the board is a power transmitter made from a Tesla Coil constructed from two Barker & Williamson ready-made coils. Three more of the inner coil are also used as power receivers. The outer, larger diameter coil is a few turns taken from one of their standard coils and organised so that the coil wire length is one quarter of the coil wire length of the inner coil ("L2").

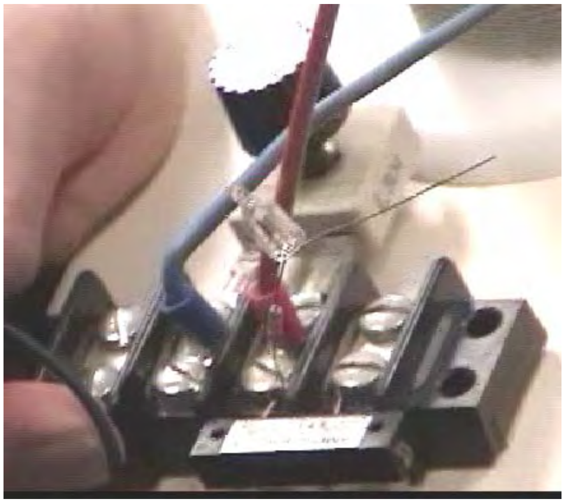
As before, a commercial neon-tube driver module is used to power the "L1" outer coil with high voltage and high frequency. It should be understood that as power is drawn from the local environment each time the power driving the transmitter coil "L1" cycles, that the power available is very much higher at higher frequencies. The power at mains frequency of less than 100 Hz is far, far less than the power available at 35,000 Hz, so if faced with the choice of buying a 25 kHz neon-tube driver module or a 35 kHz module, then the 35 kHz module is likely to give a much better output power at every voltage level.

HIGH VOLTAGE

The "L1" short outer coil is held in a raised position by the section of white plastic pipe in order to position it correctly relative to the smaller diameter "L2" secondary coil. Again, it appears to have five turns:

HIGH VOLTAGE
DANGER

The secondary coils are constructed using Barker & Williamson's normal method of using slotted strips to hold the tinned, solid copper wire turns in place.

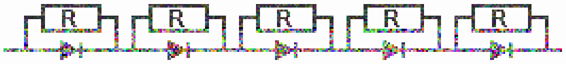


As there are very slight differences in the manufactured coils, each one is tuned to the exact transmitter frequency and a miniature neon is used to show when the tuning has been set correctly.

The key feature of this device is the fact that any number of receiver coils can be placed near the transmitter and each will receive a full electrical pick up from the local environment, without altering the power needed to drive the Tesla Coil transmitter - more and more output without increasing the input power - unlimited COP values, all of which are over 1. The extra power is flowing in from the local environment where there is almost unlimited amounts of excess energy and that inflow is caused by the rapidly vibrating magnetic field generated by the central Tesla Coil. While the additional coils appear to just be scattered around the base board, this is not the case. The YouTube video http://www.youtube.com/watch?v=TiNEHZRm4z4&feature=related demonstrates that the pick-up of these coils is affected to a major degree by the distance from the radiating magnetic field. This is to do with the wavelength of the signal driving the Tesla Coil, so the coils shown above are all positioned at exactly the same distance from the Tesla Coil. You still can have as many pick-up coils as you want, but they will be mounted in rings around the Tesla Coil and the coils in each ring will be at the same distance from the Tesla Coil in the centre.

Each of the pick up coils act exactly the same as the "L2" secondary coil of the Tesla Coil transmitter, each picking up the same level of power. Just as with the actual "L2" coil, each will need an output circuit arrangement as described for the previous device. Presumably, the coil outputs could be connected in parallel to increase the output amperage, as they are all resonating at the same frequency and in phase with each other. Each will have its own separate output circuit with a step-down isolation transformer and frequency adjustment as before. If any output is to be a rectified DC output, then no frequency adjustment is needed, just rectifier diodes and a smoothing capacitor following the step-down transformer which will need to be an air core or ferrite core type due to the high frequency. High voltage capacitors are very expensive. The http://www.richieburnett.co.uk/parts.html web site shows various ways of making your own high-voltage capacitors and the advantages and disadvantages of each type.

There are two practical points which need to be mentioned. Firstly, as the Don Smith devices shown above feed radio frequency waveforms to coils which transmit those signals, it may be necessary to enclose the device in an earthed metal container in order not to transmit illegal radio signals. Secondly, as it can be difficult to obtain high-voltage high-current diodes, they can be constructed from several lower power diodes. To increase the voltage rating, diodes can be wired in a chain. Suitable diodes are available as repair items for microwave ovens. These typically have about 4,000 volt ratings and can carry a good level of current. As there will be minor manufacturing differences in the diodes, it is good practice to connect a high value resistor (in the 1 to 10 megohm range) across each diode as that ensures that there is a roughly equal voltage drop across each of the diodes:



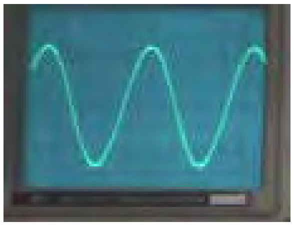
If the diode rating of these diodes were 4 amps at 4,000 volts, then the chain of five could handle 4 amps at 20,000 volts. The current capacity can be increased by connecting two or more chains in parallel.

Various questions from readers indicate that the operation of AC circuits is not really understood, so electronics experts can skip this next section.

AC Circuits. This is a lightweight introduction to Alternating Current circuits and pulsed DC circuits for people who have not read Chapter 12 which is an electronics tutorial. Let me say again, that I am mainly self-taught, and so this is just a general introduction based on my present understanding.

Alternating Current, generally called “AC” is called that because the voltage of this type of power supply is not a constant value. A car battery, for instance, is DC and has a fairly constant voltage usually about 12.8 volts when in it’s fully charged state. If you connect a voltmeter across a car battery and watch it, the voltage reading will not change. Minute after minute it says exactly the same because it is a DC source.

If you connect an AC voltmeter across an AC power supply, it too will give a steady reading, but it is telling a lie. The voltage is changing all the time in spite of that steady meter reading. What the meter is doing is **assuming** that the AC waveform is a sine wave like this:



and based on that assumption, it displays a voltage reading which is called the “Root Mean Square” or “RMS” value. The main difficulty with a sine wave is that the voltage is below zero volts for exactly the same length of time as it is above zero volts, so if you average it, the result is zero volts, which is not a satisfactory result because you can get a shock from it and so it can’t be zero volts, no matter what the arithmetical average is.

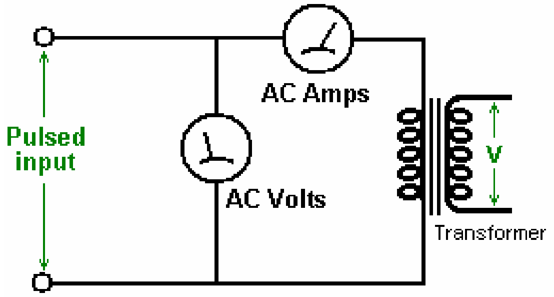
To get over this problem, the voltage is measured thousands of times per second and the results squared (that is, the value is multiplied by itself) and then those values are averaged. This has the advantage that when the voltage is say, minus 10 volts and you square it, the answer is plus 100 volts. In fact, all of the answers will be positive, which means that you can add them together, average them and get a sensible result. However, you end up with a value which is far too high because you squared every measurement, and so you need to take the square root of that average (or "mean") value, and that is where the fancy sounding "Root Mean Square" name comes from – you are taking the (square) root of the (average or) mean value of the squared measurements.

With a sine wave like this, the voltage peaks are 41.4% higher than the RMS value which everyone talks about. This means that if you feed 100 volts AC through a rectifier bridge of four diodes and feed it into a capacitor the capacitor voltage will **not** be 100 volts DC but instead it will be 141.4 volts DC and you need to remember that when choosing the voltage rating of the capacitor. In that instance I would suggest a capacitor which is made to operate with voltages up to 200 volts.

You probably already knew all of that, but it may not have occurred to you that if you use a standard AC voltmeter on a waveform which is **not** a sine wave, that the reading on the meter is most unlikely to be correct or anywhere near correct. So, please don't merrily connect an AC voltmeter across a circuit which is producing sharp voltage spikes like, for instance, one of John Bedini's battery pulsing circuits, and think that the meter reading means anything (other than meaning that you don't understand what you are doing).

You will, hopefully, have learned that power in watts is determined by multiplying the current in amps by the voltage in volts. For example, 10 amps of current flowing out of a 12 volt power supply, represents 120 watts of power. Unfortunately, that only holds true for circuits which are operating on DC, or AC circuits which have only resistors in them. The situation changes for AC circuits which have non-resistive components in them.

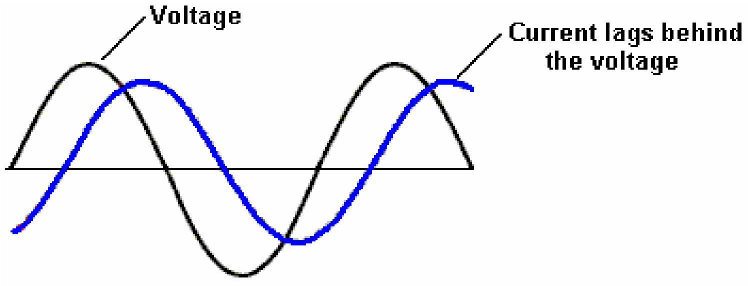
The circuits of this type which you are likely to come across are circuits which have coils in them, and you need to think about what you are doing when you deal with these types of circuit. For example, consider this circuit:



This is the output section of a prototype which you have just built. The input to the prototype is DC and measures at 12 volts, 2 amps (which is 24 watts). Your AC voltmeter on the output reads 15 volts and your AC ammeter reads 2.5 amps and you are delighted because 15 x 2.5 = 37.5 which looks much bigger than the 24 watts of input power. **But**, just before you go rushing off to announce on YouTube that you have made a prototype with COP = 1.56 or 156% efficient, you need to consider the real facts.

This is an AC circuit and unless your prototype is producing a perfect sine wave, then the AC voltmeter reading will be meaningless. It is just possible that your AC ammeter is one of the few types that can accurately measure the current no matter what sort of waveform is fed to it, but it is distinctly possible that it will be a digital meter which assesses current by measuring the AC voltage across a resistor in series with the output, and if that is the case, it will probably be assuming a sine wave. The odds are that both readings are wrong, but let's take the case where we have great meters which are reading the values perfectly correctly. Then the output will be 37.5 watts, won't it? Well, actually, no it won't. The reason for this is that the circuit is feeding the transformer winding which is a coil and coils don't work like that.

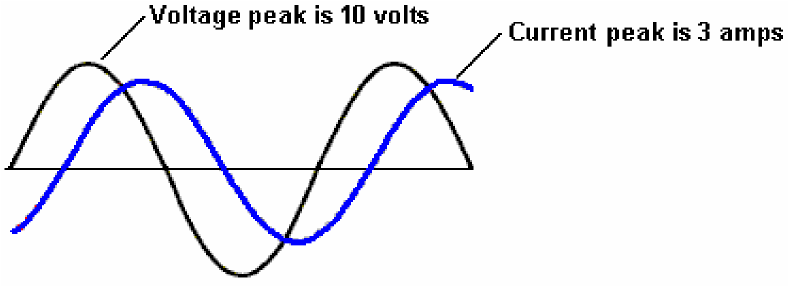
The problem is that, unlike a resistor, when you apply a voltage across a coil the coil starts absorbing energy and feeding it into the magnetic field around the coil, so there is a delay before the current reaches it's maximum value. With DC, this generally doesn't matter very much, but with AC where the voltage is changing continuously, it matters a great deal. The situation can be as shown in this graph of both voltage and current:



Voltage
Current lags behind the voltage

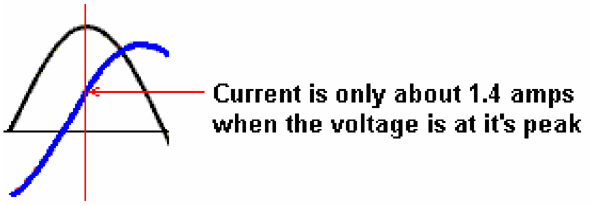
At first, this does not look like any great problem, but it has a very significant effect on the actual power in watts. To get the 37.5 watts output which we were talking about earlier, we multiplied the average voltage level by the average current level. But these two values do not occur at the same time and that has a major effect.

As this can be a little difficult to see, let's take the peak values rather than the averages as they are easier to see. Let's say that in our example graph that the voltage peak is 10 volts and the current peak is 3 amps. If this were DC we would multiply them together and say that the power was 30 watts. But with AC, this does not work due to the timing difference:



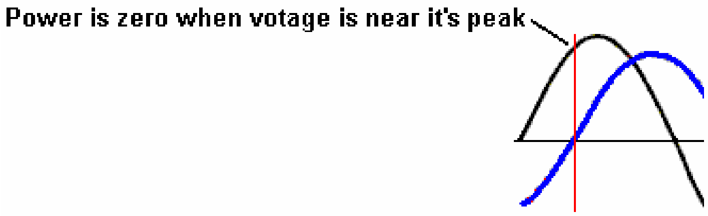
Voltage peak is 10 volts
Current peak is 3 amps

When the voltage is peaking, the current is nowhere near it's peak value of 3 amps:



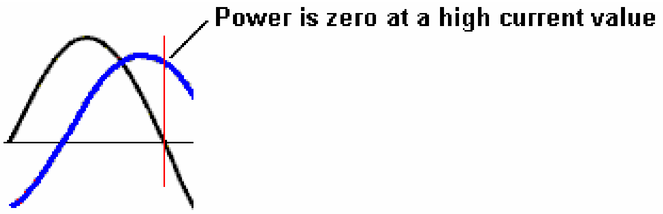
Current is only about 1.4 amps when the voltage is at it's peak

As a result of this, instead of getting our expected peak power at the top of the voltage peak, the actual power in watts is very much lower – less than half of what we were expecting. Not so good, but it gets worse when you look at the situation more closely. Take a look at what the voltage is when the current crosses the zero line, that is, when the current is zero. The output power is zero when the current is zero but this occurs when the voltage is at a very high value:



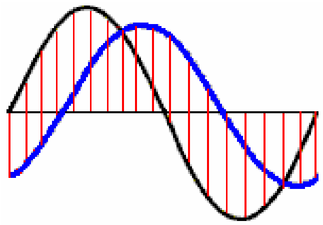
Power is zero when votage is near it's peak

The same goes for when the voltage is zero. When the voltage is zero, then the power is also zero, and you will notice that this occurs when the current is at a high value:



The power is **not** the average current multiplied by the average voltage if there is a coil involved in the circuit – it will be less than that by an amount known as the "power factor" and I'll leave you to work out why it is called that.

So, how do you determine what the power is? It is done by sampling the voltage and current many times per second and averaging those combined results:



Both the voltage and the current are sampled at the times indicated by the vertical red lines and those figures are used to calculate the actual power level. In this example, only a few samplings are shown, but in practice, a very large number of samples will be taken. The piece of equipment which does this is known as a wattmeter as it measures watts of power. The sampling can be done by windings inside the instrument, resulting in an instrument which can be damaged by overloading without the needle being anywhere near full deflection, or it can be done by digital sampling and mathematical integration. Most digital sampling versions of these meters only operate at high frequencies, typically over 400,000 cycles per second. Both varieties of wattmeter can handle any waveform and not just sine waves.

The power company supplying your home, measures the current and assumes that the full voltage is present during all of the time that the current is being drawn. If you are powering a powerful electric motor from the mains, then this current lag will cost you money as the power company does not take it into account. It is possible to correct the situation by connecting one or more suitable capacitors across the motor to minimise the power loss.

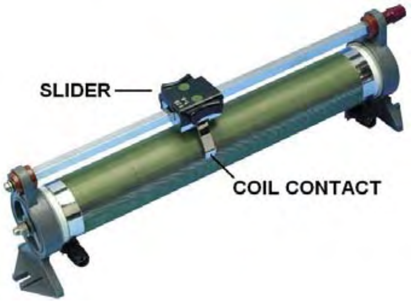
With a coil (fancy name "inductor" symbol "L"), AC operation is very different to DC operation. The coil has a DC resistance which can be measured with the ohms range of a multimeter, but that resistance does not apply when AC is being used as the AC current flow is **not** determined by the DC resistance of the coil. Because of this, a second term has to be used for the current-controlling factor of the coil, and the term chosen is "impedance" or for people who like to make everything sound unduly complicated "reactance". I will stick with the term "impedance" as it is clear that it is the feature of the coil which "impedes" AC current flow through the coil.

The impedance of a coil depends on it's size, shape, method of winding, number of turns and core material. It also depends on the frequency of the AC voltage being applied to it. If the core is made up of iron or steel, usually thin layers of iron which are insulated from each other, then it can only handle low frequencies. You can forget about trying to pass 10,000 cycles per second ("Hz") through the coil as the core just can't change it's magnetic poles fast enough to cope with that frequency. A core of that type is ok for the very low 50 Hz or 60 Hz frequencies used for mains power, which are kept that low so that electric motors can use it.

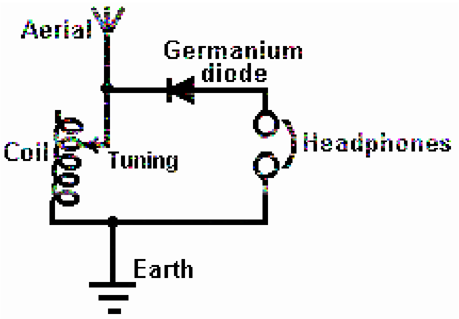
For higher frequencies, ferrite can be used for a core and that is why some portable radios use ferrite-rod aerials, which are a bar of ferrite with a coil wound on it. For higher frequencies (or higher efficiencies) iron dust encapsulated in epoxy resin is used. An alternative is to not use any core material and that is usually referred to as an "air-core" coil. These are not limited in frequency by the core but they have a very much lower inductance for any given number of turns. The efficiency of the coil is called it's "Q" (for "Quality") and the higher the Q factor, the better. The resistance of the wire lowers the Q factor.

A coil has inductance, and resistance caused by the wire, and capacitance caused by the turns being near each other. However, having said that, the inductance is normally so much bigger than the other two components that we tend to ignore the other two. Something which may not be immediately obvious is that the impedance to AC current flow through the coil depends on how fast the voltage is changing. If the AC voltage applied to a coil completes one cycle every ten seconds, then the impedance will be much lower than if the voltage cycles a million times per second.

If you had to guess, you would think that the impedance would increase steadily as the AC frequency increased. In other words, a straight-line graph type of change. That is not the case. Due to a feature called resonance, there is one particular frequency at which the impedance of the coil increases massively. This is used in the tuning method for AM radio receivers. In the very early days when electronic components were hard to come by, variable coils were sometimes used for tuning. We still have variable coils today, generally for handling large currents rather than radio signals, and we call them "rheostats" and some look like this:

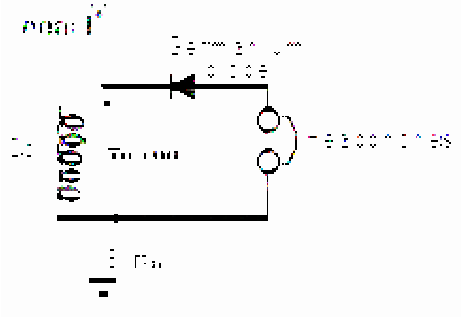


These have a coil of wire wound around a hollow former and a slider can be pushed along a bar, connecting the slider to different winds in the coil depending on it's position along the supporting bar. The terminal connections are then made to the slider and to one end of the coil. The position of the slider effectively changes the number of turns of wire in the part of the coil which is being used in the circuit. Changing the number of turns in the coil, changes the resonant frequency of that coil. AC current finds it very, very hard to get through a coil which has the same resonant frequency as the AC current frequency. Because of this, it can be used as a radio signal tuner:



If the coil's resonant frequency is changed to match that of a local radio station by sliding the contact along the coil, then that particular AC signal frequency from the radio transmitter finds it almost impossible to get through the coil and so it (and only it) diverts through the diode and headphones as it flows from the aerial wire to the earth wire and the radio station is heard in the headphones. If there are other radio signals coming down the aerial wire, then, because they are not at the resonant frequency of the coil, they flow freely through the coil and don't go through the headphones.

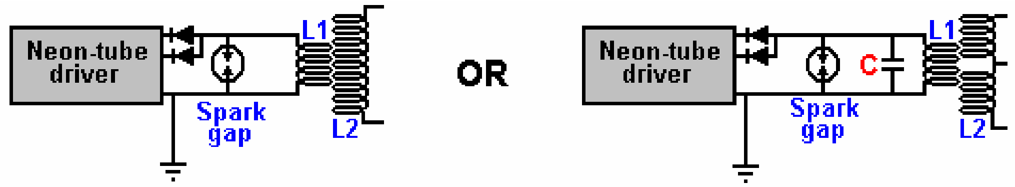
This system was soon changed when variable capacitors became available as they are cheaper to make and they are more compact. So, instead of using a variable coil for tuning the radio signal, a variable capacitor connected across the tuning coil did the same job:



While the circuit diagram above is marked "Tuning capacitor" that is actually quite misleading. Yes, you tune the radio receiver by adjusting the setting of the variable capacitor, **but**, what the capacitor is doing is altering the resonant frequency of the coil/capacitor combination and it is the resonant frequency of that combination which is doing exactly the same job as the variable coil did on it's own.

This draws attention to two very important facts concerning coil/capacitor combinations. When a capacitor is placed across a coil "in parallel" as shown in this radio receiver circuit, then the combination has a very high impedance (resistance to AC current flow) at the resonant frequency. But if the capacitor is placed "in series" with the coil, then there is nearly zero impedance at the resonant frequency of the combination:

This may seem like something which practical people would not bother with, after all, who really cares? However, it is a very practical point indeed. Remember that Don Smith often uses an early version, off-the-shelf neon-tube driver module as an easy way to provide a high-voltage, high-frequency AC current source, typically, 6,000 volts at 30,000 Hz. He then feeds that power into a Tesla Coil which is itself, a power amplifier. The arrangement is like this:



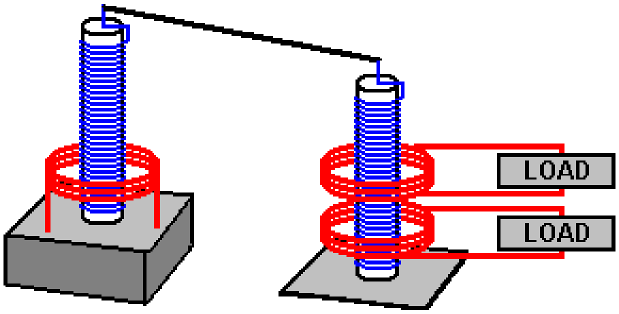
People who try to replicate Don's designs tend to say "I get great sparks at the spark gap until I connect the **L1** coil and then the sparks stop. This circuit can never work because the resistance of the coil is too low".

If the resonant frequency of the **L1** coil does not match the frequency being produced by the neon-tube driver circuit, then the low impedance of the **L1** coil at that frequency, will definitely pull the voltage of the neon-tube driver down to a very low value. But if the **L1** coil has the same resonant frequency as the driver circuit, then the **L1** coil (or the **L1** coil/capacitor combination shown on the right, will have a very high resistance to current flow through it and it will work well with the driver circuit. So, no sparks, means that the coil tuning is off. It is the same as tuning a radio receiver, get the tuning wrong and you don't hear the radio station.

This is very nicely demonstrated using simple torch bulbs and two coils in the YouTube video showing good output for almost no input power: http://www.youtube.com/watch?v=kQdcwDCBoNY and while only one resonant pick-up coil is shown, there is the possibility of using many resonant pick-up coils with just the one transmitter.

It should be stated that people have tried to replicate the devices which Don has described and have not been successful. Consequently, they believe that Don's presentations are a hoax and that he has never had any device which worked as he claimed. That is a rather doubtful conclusion to draw as the only certain thing which can be concluded is that they failed in their attempt. It is my experience that some people who attempt replications do not seem to have the 'knack' or perseverance needed to reach a successful result, while others do have what it takes. For example, many people tried to replicate Stan Meyer's water-splitter which he called his "Water Fuel Cell" or "WFC" for short, and they did not succeed. Dave Lawton in Wales decided to produce a replication and he had zero success for a whole month of effort. After a month of trying, his cell suddenly bust into substantial gas production, showing that the electrode pipes had to be "conditioned" before the cell would work properly. Most people would have given up long before the month was up, and declared that the WFC was a hoax. As a result of Dave's efforts and his generous sharing of what he did (in chapter 10), many people have now been very successful in replicating Stan Meyer's design. So, I will leave it up to you to decide if Don Smith's devices are a hoax. It should be understood, that there is no particular reason why anyone who was successful with Don's designs would necessarily tell me. Most will never even have heard of me.

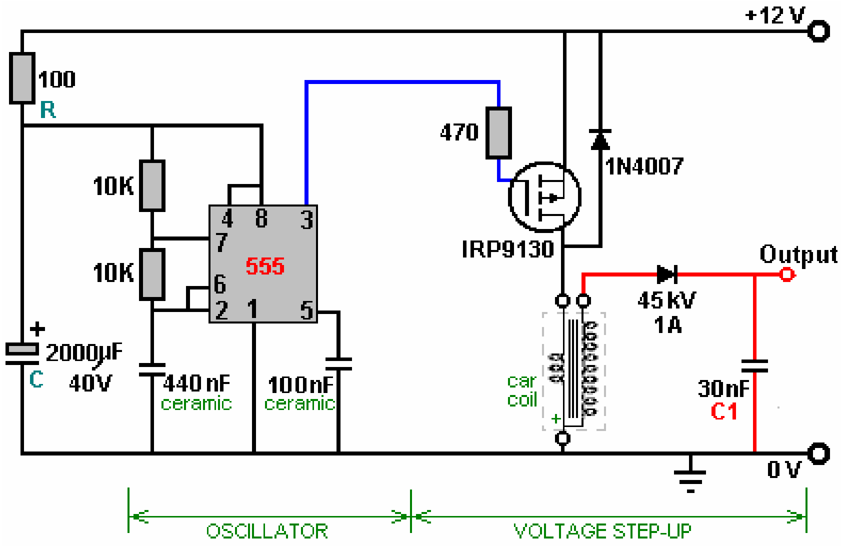
Bearing that in mind, I have been told of one man who used his common sense and produced an impressive result. He used a Tesla Coil as the driving force, and then used a second Tesla Coil back-to-back with the first one, to step the high voltage back down again. Doing that, he was able to light a series of powerful light bulbs from the "L1" output coils. He also confirmed that doubling the voltage, quadrupled the power output, verifying what Don said. He also found that adding additional coils with bulbs to the output Tesla Coil, did not increase the input power at all, did not cause any of the existing light bulbs to shine any less brightly, and yet lit the additional bulbs. That would appear to be confirmation of Don's statement that any number of magnetic copies of the original oscillating magnetic field of the first Tesla Coil, can provide a full-power electrical output without requiring any additional input power. I'm no expert, but my understanding of the arrangement is:



As the large diameter coil is exactly one quarter the length of the smaller diameter coil, there is an automatic resonance of both when the applied frequency is just right. As the first narrow coil is identical to the second narrow coil, they are also automatically resonant together. Again, as the large coils which feed the loads are exactly one quarter the wire length of the narrow coils, they also resonate at the common frequency and at that frequency, the input power is at its minimum while the output power is at its maximum. The spike at the top of each of the narrow coils is connected with a wire to channel the generated power from the first Tesla Coil to the second one.

As some readers may feel that there is some "black magic" about the neon-driver circuit used by Don to drive the Tesla Coil section of his circuitry and that if a suitable unit could not be purchased then the circuit could not be reproduced or tested, it seems reasonable to show how it operates and how it can be constructed from scratch:

The circuit itself is made up of an oscillator to convert the 12-volt DC supply into a pulsating current which is then stepped up to a high voltage by a transformer. Here is a circuit which has been used for this:



The supply for the 555 timer chip is protected against spikes and dips by the resistor "R" and the capacitor "C". The 555 timer chip acts as an oscillator or "clock" whose speed is governed by the two 10K resistors feeding the 440 nF capacitor. The step-up transformer is an ordinary car coil and the drive power to it is boosted by the IRP9130 FET transistor which is driven by the 555 chip output coming from it's pin 3.

The output from the (Ford Model T) car coil is rectified by the diode, which needs to have a very high voltage rating as the voltage at this point is now very high. The rectified voltage pulses are stored in a very high-voltage capacitor before being used to drive a Tesla Coil. As a powerful output is wanted, two car coils are used and their outputs combined as shown here:

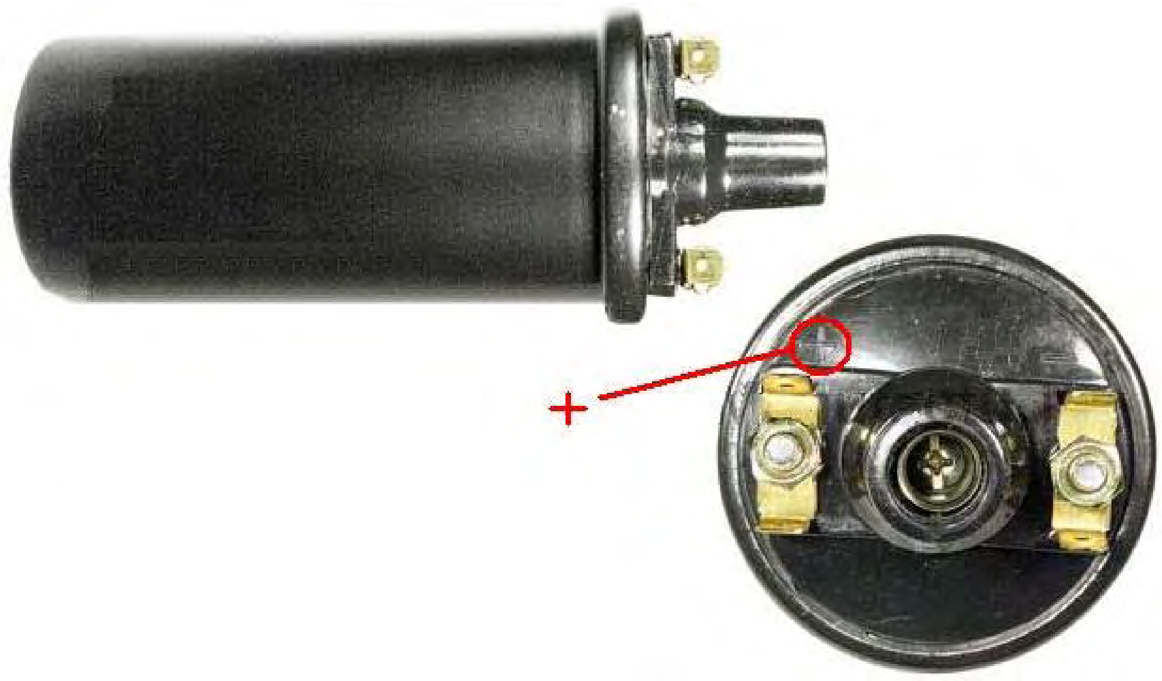
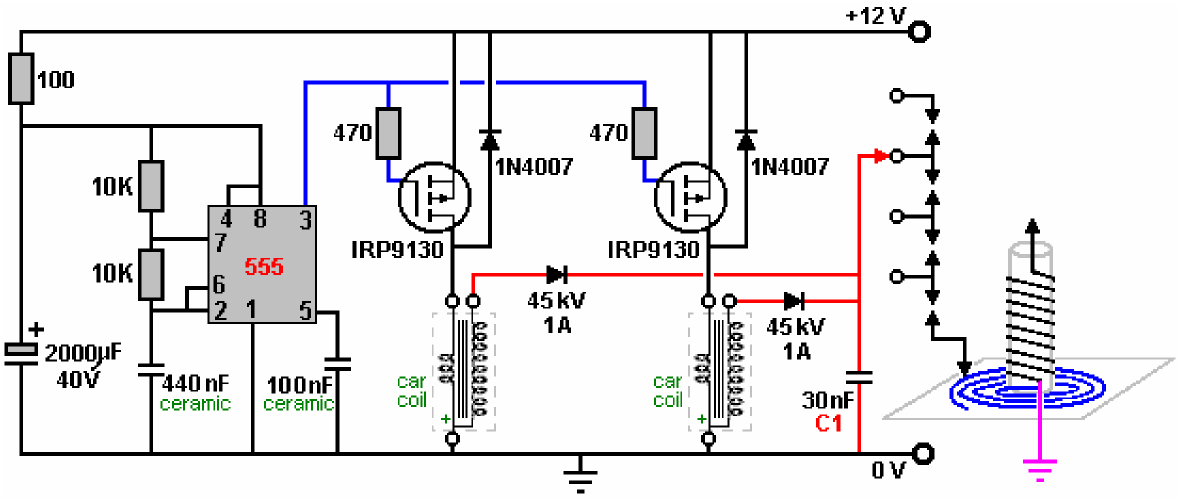
You will notice that the car coil has only three terminals and the terminal marked "+" is the one with the connection common to both of the coils inside the housing. The coil may look like this:

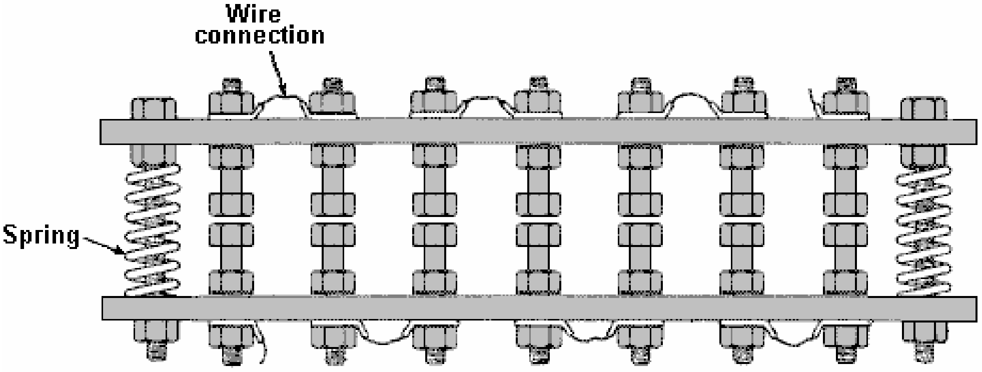


and the "+" is generally marked on the top beside the terminal with the two internal connections running to it. The circuit described so far is very close to that provided by a neon-tube driver circuit and it is certainly capable of driving a Tesla Coil.

There are several different way of constructing a Tesla Coil. It is not unusual to have several spark gaps connected in a chain. This arrangement is called a "series spark gap" because the spark gaps are connected "in series" which is just a technical way of saying "connected in a row". In the chapter on aerial systems, you will see that Hermann Plauston uses that style of spark gap with the very high voltages which he gets from his powerful aerial systems. These multiple spark gaps are much quieter in operation than a single spark gap would be. One of the possible Tesla Coil designs uses a pancake coil as the "L1" coil as that gives even higher gain. The circuit is as shown here:



The connection to the pancake coil is by a moveable clamp and the two coils are tuned to resonance by careful and gradual adjustment of that connection. The series spark gap can be constructed in various ways, including using car spark plugs. The one shown here uses nuts and bolts projecting through two strips of a stiff, non-conducting material, as that is much easier to adjust than the gaps of several spark plugs:



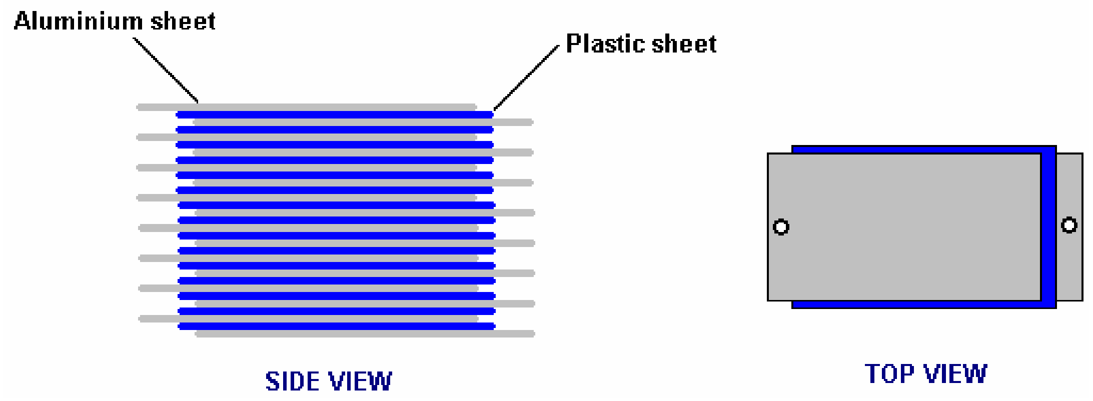
Tightening the bolts which compress the springs moves the bolt heads closer together and reduces all of the spark gaps. The electrical connections can be made to the end tags or to any of the intermediate wire connection straps if fewer spark gaps are required in the chain.

Let me remind you again that this is not a toy and very high voltages will be produced. Also, let me stress again that if you decide to construct anything, then you do so entire on your own responsibility. This document is only provided for information purposes and must not be seen as an encouragement to build any such device nor is any guarantee given that any of the devices described in this eBook will work as described should you decide to attempt to construct a replication prototype of your own. Generally, it takes skill and patience to achieve success with any free-energy device and Don Smith's devices are some of the most difficult, especially since he admits quite freely that he does not disclose all of the details.

The output capacitor marked "C1" in the circuit diagram above has to be able to handle very high voltages. There are various ways of dealing with this. Don dealt with it by getting very expensive capacitors manufactured by a specialist company. Some home-based constructors have had success using glass beer bottles filled with a salt solution. The outside of the bottles are wrapped in aluminium foil to form one of the contacts of the capacitor and bare wires are looped from deep inside each bottle on to the next one, looping from the inside of one bottle to the inside of the next one, and eventually forming the other contact of the capacitor. While that appears to work well, it is not a very convenient thing to carry around. An alternative is just to stand the bare bottles in a container which is lined with foil which forms the second contact of the capacitor.

One method which has been popular in the past is to use two complete rolls of aluminium foil, sometimes called "baking foil", laying them one flat, covering it with one or more layers of plastic cling film and laying the second roll of foil on top of the plastic. The three layers are then rolled up to form the capacitor. Obviously, several of these can be connected together in parallel in order to increase the capacitance of the set. The thicker the plastic, the lower the capacitance but the higher the voltage which can be handled.

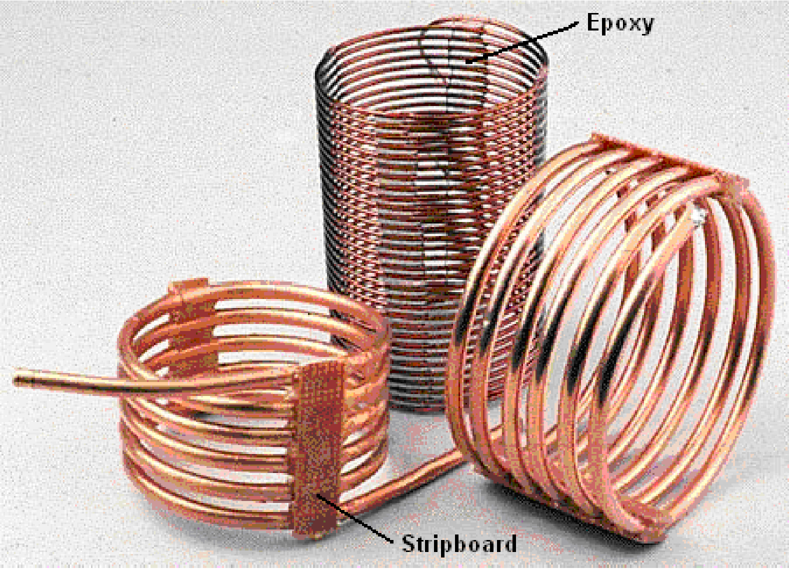
The November 1999 issue of Popular Electronics suggests using 33 sheets of the thin aluminium used as a flashing material by house builders. At that time it was supplied in rolls which were ten inches (250 mm) wide, so their design uses 14" (355 mm) lengths of the aluminium. The plastic chosen to separate the plates was polythene sheet 0.062 inch (1.6 mm) thick which is also available from a builders merchants outlet. The plastic is cut to 11 inch (280 mm) by 13 inch (330 mm) and assembly is as follows:



The sandwich stack of sheets is then clamped together between two rigid timber sheets. The tighter that they are clamped, the closer the plates are to each other and the higher the capacitance. The electrical connections are made by running a bolt through the projecting ends of the plates. With two thicknesses of plastic sheet and one of aluminium, there should be room for a washer between each pair of plates at each end and that would improve the clamping and the electrical connection. An alternative is to cut a corner off each plate and position them alternatively so that almost no plate area is ineffective.

As Don Smith has demonstrated in one of his video presentations, Nikola Tesla was perfectly correct when he stated that directing the discharge from a Tesla Coil on to a metal plate (or in Don's case, one of the two metal plates of a two-plate capacitor where a plastic sheet separates the plates just as shown above), produces a very powerful current flow onwards through a good earth connection. Obviously, if an electrical load is positioned between the plates and the earth connection, then the load can be powered to a high level of current, giving a very considerable power gain.

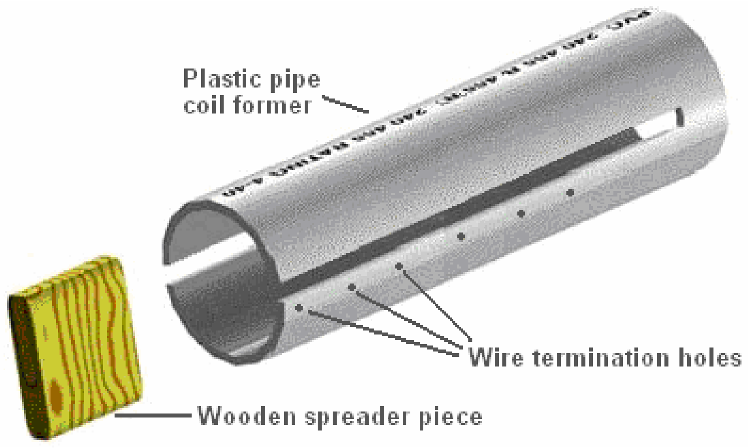
Coil Construction: The Barker & Williamson coils used by Don in his constructions are expensive to purchase. Some years ago, in an article in a 1997 issue of the “QST” amateur radio publication, Robert H. Johns shows how similar coils can be constructed without any great difficulty. The Electrodyne Corporation research staff have stated that off-the-shelf solid tinned copper wire produces three times the magnetic field that un-tinned copper does, so perhaps that should be borne in mind when choosing the wire for constructing these coils.



These home-made coils have excellent "Q" Quality factors, some even better than the tinned copper wire coils of Barker & Williamson because the majority of electrical flow is at the surface of the wire and copper is a better conductor of electricity than the silver tinning material.

The inductance of a coil increases if the turns are close together. The capacitance of a coil decreases if the turns are spread out. A good compromise is to space the turns so that there is a gap between the turns of one wire thickness. A common construction method with Tesla Coil builders is to use nylon fishing line or plastic strimmer cord between the turns to create the gap. The method used by Mr Johns allows for even spacing without using any additional material. The key feature is to use a collapsible former and wind the coil on the former, space the turns out evenly and then clamp them in position with strips of epoxy resin, removing the former when the resin has set and cured.

Mr Johns has difficulty with his epoxy being difficult to keep in place, but when mixed with the West System micro fibres, epoxy can be made any consistency and it can be applied as a stiff paste without any loss of it's properties. The epoxy is kept from sticking to the former by placing a strip of electrical tape on each side of the former.



I suggest that the plastic pipe used as the coil former is twice the length of the coil to be wound as that allows a good degree of flexing in the former when the coil is being removed. Before the two slots are cut in the plastic pipe, a wooden spreader piece is cut and it's ends rounded so that it is a push-fit in the pipe. This spreader piece is used to hold the sides of the cut end exactly in position when the wire is being wrapped tightly around the pipe.

Two or more small holes are drilled in the pipe beside where the slots are to be cut. These holes are used to anchor the ends of the wire by passing them through the hole and bending them. Those ends have to be cut off before the finished coil is slid off the former, but they are very useful while the epoxy is being applied and hardening. The pipe slots are cut to a generous width, typically 10 mm or more.

The technique is then to wedge the wooden spreader piece in the slotted end of the pipe. Then anchor the end of the solid copper wire using the first of the drilled holes. The wire, which can be bare or insulated, is then wrapped tightly around the former for the required number of turns, and the other end of the wire secured in one of the other drilled holes. It is common practice to make the turns by rotating the former. When the winding is completed, the turns can be spaced out more evenly if necessary, and then a strip of epoxy paste applied all along one side of the coil. When that has hardened, (or immediately if the epoxy paste is stiff enough), the pipe is turned over and a second epoxy strip applied to the opposite side of the coil. A strip of paxolin board or strip-board can be made part of the epoxy strip. Alternatively, an L-shaped plastic mounting bracket or a plastic mounting bolt can be embedded in the epoxy ready for the coil installation later on.

When the epoxy has hardened, typically 24 hours later, the coil ends are snipped off, the spreader piece is tapped out with a dowel and the sides of the pipe pressed inwards to make it easy to slide the finished coil off the former. Larger diameter coils can be wound with small-diameter copper pipe.

The coil inductance can be calculated from:

Inductance in microhenrys $L = d^2n^2 / (18d + 40l)$

Where:
d is the coil diameter in inches measured from wire centre to wire centre
n is the number of turns in the coil
l is coil length in inches (1 inch = 25.4 mm)

Using this equation for working out the number of turns for a given inductance in microhenrys:

$$n = \frac{\sqrt{L(18d + 40l)}}{d}$$

REX MILLER & MARK MILLER

Electricity and Electronics for HVAC

ABOUT THE AUTHOR

Rex Miller is Professor Emeritus of Industrial Technology at the SUNY College at Buffalo. He has taught technical curriculums at the high school, technical school, and college levels for more than 40 years. Dr. Miller is the author or coauthor of over 100 textbooks for vocational and industrial arts programs, including McGraw-Hill's best-selling *Carpentry and Construction* and *Electrician's Pocket Manual*.

Mark R. Miller is Professor and Coordinator of Industrial Technology at the University of Texas at Tyler. He has taught technical curriculums at the high school, technical school, and college levels for more than 25 years. Dr. Miller is the author or coauthor of over 30 textbooks for trade and technical programs, including McGraw-Hill's *Welding Licensing Exam Study Guide* and *Air Conditioning and Refrigeration.*

Contents

Preface xvii
Acknowledgments xix

Chapter 1. Introduction to Electricity 1

Performance Objectives 1
Introduction to Electricity 1
Static Electricity and Magnetism 2
Electricity 2
Electricity's Future 3
Matter and Electricity 4
  Solids, gases, and liquids 4
Atom 5
  Electrons, protons, and neutrons 6
Properties of Electrons 8
Orbiting Electrons 8
Electrical Charge 9
Outer Shell 10
  Valence electrons and ions 10
A Practical Unit of Charge 12
The Volt 12
Controlling Electrons 13
Difference of Potential (Voltage) 13
Electron Flow (Current) 14
Conductors 14
Resistance 14
The Electric Circuit 15
Connecting a Circuit 16
Switches Control Electron Flow 16
Schematic 17
Review Questions 17

Chapter 2. Current, Voltage, Resistance, Power, and Ohm's Law 19

Performance Objectives 19
Sources of Electricity 19
  Chemical action 19
  Heat 19
  Light 20
  Pressure 20
  Magnetism 20
Units of Measurement 21
  Unit of charge: coulomb 21
  Unit of current: ampere 22
  Unit of potential difference: volt 22
  Unit of resistance: ohm 22
  Siemens 23
Prefixes 23
Ohm's Law 24
  Ohm's law examples 25
  Ohm's law and the closed circuit 27
  Ohm's law in other forms 29
  Uses for ohm's law 30
Power 31
Joule 31
Watt 32
Putting Electricity to Work 32
  Resistors and heat 32
  Mechanical energy 32
A Practical Unit of Electrical Power: Kilowatt-Hour 34
Review Questions 35

Chapter 3. Resistors, Other Electric Components, and Their Symbols 37

Performance Objectives 37
Color Code 38
  Tolerance 39
  Examples 39
  Gold and silver third bands 40
Variable Resistors 41
Schematic 43
Types of Resistors 43
  Fixed resistors 43
  Tapped resistors 44
  Variable resistors 44
  Fusible resistors 44
  Temperature-compensating resistors 47
Types of Capacitors 47
  Fixed capacitors 47
  Electrolytic capacitors 48
  Variable capacitors 49
Types of Inductors 50
  Fixed inductors 50
  Variable inductors 51
Transformers 51

Semiconductors 52
  Diodes 52
  Transistors 52
Switches 53
Relays 53
Fuses and Circuit Breakers 53
Lamps 55
  Batteries 56
  Meters 57
Reading Schematics 57
Review Questions 57

Chapter 4. Series and Parallel Circuits 59

Performance Objectives 59
Series Circuit 59
  Resistances in series 61
  Voltages in series 61
  Current in series 61
  Series circuit rules 62
  Fuses 62
Parallel Circuit 63
  Cells in parallel 63
  Parallel circuit characteristics 63
  Currents in a parallel circuit 64
  Resistances in a parallel circuit 64
  Parallel circuit rules 65
Series-Parallel Circuits 65
  Series-parallel resistance circuits 66
  Determining resistance 66
  Determining current in series-parallel circuits 68
  Determining voltage in series-parallel circuits 68
Review Questions 72

Chapter 5. Magnetism, Solenoids, and Relays 73

Performance Objectives 73
Permanent Magnets 74
Temporary Magnets 75
Electromagnets 75
Magnetic Theory 76
Magnetic Permeability 76
Shapes of Magnets 76
  Poles of magnets 78
Electromagnetism 79
  Magnetism in a coil of wire 80
  Electromagnets 80
  Using electromagnetism 82
The Solenoids and Relays 82
  Power relays 86
  Solenoid valves 86
  Principles of operation 86
Applications 87
  Liquid line service 87
  Suction line service 89

High-Temperature Applications 89
  Hot-gas defrost service 90
Transformers for Low-Voltage Controls 91
Review Questions 92

Chapter 6. Electrical Measuring Instruments 93

Performance Objectives 93
Electricity 93
Types of Meter Movements 94
  D'Arsonval meter movement 94
  Analog meters 97
Parallax Error 97
Ammeters 98
  Extending the range of an ammeter 99
  Connecting an ammeter in the circuit 99
  Clamp-on ammeters 99
  AC ammeters 101
Voltmeters 101
  Connecting a voltmeter 102
AC Voltmeters 102
Ohmmeters 103
Multimeters 103
Meggers 104
Digital Meters 104
Other Instruments 106
  Automatic halogen leak detector 106
  Electronic sight glass 107
  Electronic charging meters 107
Using an Ohmmeter 108
  Warning 108
  Adjusting the meter 108
Review Questions 110

Chapter 7. Electrical Power: Direct Current and Alternating Current 111

Performance Objectives 111
Power Sources 111
Types of Batteries 112
  Primary cell 112
  Secondary cell 112
Dry Cells 112
Battery Specifications 115
Connecting Cells 115
Battery Maintenance 118
Nickel-Cadmium Cells 119
Alkaline Cells 119
Alternating Current 119
Sine Wave 120
Sine-Wave Characteristics 121
Phase 122
Average, RMS, and Peak Values of AC 122

Polyphase Alternating Current 123
  Three phase 124
  Three-phase connections 124
Electrical Properties of Delta and Wye 126
  Delta connection (Δ) 126
  Wye connection (Y) 126
  Delta and wye summarized 126
Review Questions 127

Chapter 8. Inductors and Transformers 129

Performance Objectives 129
Changing Inductance 130
Self-Inductance 130
Mutual Inductance 133
Inductive Reactance 134
  Measuring X_L 134
Power in an Inductive Circuit 134
Uses for Inductive Reactance 135
Transformers 135
  Mutual inductance in a transformer 135
  Iron-core transformer 136
  Construction 137
  Types of iron-core transformers 137
Voltage Transfer 138
  Step up, step down 139
  Turns ratio 139
Power Transformers 140
Audio Frequency and Radio Frequency Transformers 140
Autotransformers 141
Transformer Losses 142
Inductive Circuits 144
  Special handling 145
Utilizing the Inductive Delay 146
Review Questions 146

Chapter 9. Capacitors and Capacitive Reactance 147

Performance Objectives 147
The Capacitor 149
How the Capacitor Works 149
Capacity of a Capacitor 150
Breakdown Voltage 151
Basic Units of Capacitance 151
Types of Capacitors 151
Electrolytic Capacitors 153
  Making an electrolytic capacitor 154
  Connecting electrolytics 154
Working Voltage, Direct Current (WVDC) 155
Capacitive Reactance 155
Capacitor Causes a Lagging Voltage 156
Checking Capacitors 157
Review Questions 158

Chapter 10. Single-Phase and Three-Phase Alternating Current 161

Performance Objectives 161
Single-Phase and Three-Phase AC 161
Resistance, Capacitance, and Inductance 162
Power Factor 164
Distributing Electric Power 165
Polyphase 166
Circuit Breakers 169
Review Questions 171

Chapter 11. Solid-State Controls 173

Performance Objectives 173
Semiconductors 173
Semiconductor Principles 174
Diode 175
Silicon-Controlled Rectifiers 177
Transistors 178
  Transistor impedances 179
Integrated Circuits 180
  Solid-state demand defrost control 182
Thermistor Sensing 182
Humidity Sensing 184
Bridge Circuit 186
  Unbalanced bridge 187
Sensors 189
Controllers 189
Electronic Controllers 189
Differential Amplifiers 190
Actuators 191
Other Devices 192
Solid-State Compressor Motor Protection 192
  Operation of the module 192
  Troubleshooting the control 194
  Restoring service 196
Review Questions 197

Chapter 12. Alternating Current Motors 199

Performance Objectives 199
Motors 199
Split-Phase Motor 204
  Getting the motor started 204
Repulsion Start, Induction Run Motor 206
Capacitor-Start Motor 208
Permanent Split-Capacitor Motor 210
  Theory of operation 212
Capacitor-Start, Capacitor-Run Motor 215
  Theory of operation 215
Three-Phase Motor 216
  Theory of operation 216

Capacitor Ratings 219
Start Capacitors and Bleeder Resistors 219
  Run capacitors 221
Motor Protectors 221
Compressor Motor Relays 221
  Current-type relay 222
  Potential-type relay 222
Review Questions 224

Chapter 13. Electrical Safety 225

Performance Objectives 225
Safety Devices 225
Safety Precautions 225
Main Switches 226
Portable Electrical Tools 227
Ground-Fault Circuit Interrupters (GFCI) 229
Types of Circuit Protectors 230
Review Questions 231

Chapter 14. Control Devices 233

Performance Objectives 233
Power Relays 233
  Motor start relays 234
  Relays with more than one contact 235
  Thermal overload protectors 236
  Time-delay relays 237
Solenoids 238
Thermostats 239
  Bellows-type thermostats 239
  Bimetallic-type thermostats 241
  Heating and cooling thermostats 242
  Microprocessor thermostats 245
Thermostat Adjustments 245
  Heat anticipators 246
  Cold anticipators 246
Switches of Many Types 246
Pressure Control Switches 247
Water Tower Controls 248
Review Questions 250

Chapter 15. Heating Circuits 251

Performance Objectives 251
Basic Gas Furnace Operation 252
Basic Electric Heating System 253
  Basic operation 253
Ladder Diagrams 254
Manufacturer’s Diagrams 257
Field Wiring 258
Low-Voltage Wiring 258

Heat Pumps 260
  Operation 261
  Special requirements of heat-pump systems 266
  Heat-pump combinations 267
High-Efficiency Furnaces 267
  Operation 268
  Electrical controls 269
  Sequence of operation 270
  Combustion process 271
Troubleshooting the Pulse Furnace 271
Review Questions 278

Chapter 16. Air-Conditioning Circuits 279

Performance Objectives 279
Basic Air-Conditioning Unit 279
  Push-button switches 282
  Fans 283
Schematics 283
Ladder Diagrams 287
  Thermostats 287
  Fan switches 291
Troubleshooting 291
Review Questions 291

Chapter 17. Refrigeration Circuits 293

Performance Objectives 293
Basic Refrigerator 293
  Thermostats 293
  Start relays 295
